Sebright Bantams—Fowls for Egg-laying (*T. S.*).—Though the hens are darker golden than the cocks, you will breed good Bantams if the colours are clear and the lacing quite distinct. They must have double combs, and the tails should be clear, tipped at the end with black. The cock should have neither hackle, saddle, nor sickle feathers. The difference in colour between the cock and pullets is probably caused by the former having some Silver blood in him. This is immaterial, as many breeders run the two colours together. We think the Houdans will be the fowls to suit best, as bearing confinement perfectly, being good layers and non-sitters.

Pigeon with Diseased Wing (*G. R.*).—It is not at all likely that the disease is infectious, nor is it likely that it will interfere with the bird's breeding. To merely say a wing is "diseased" is very indefinite.

Turbit Pigeons—Shell-crowned and Shields, &c. (*A. L. B.*).—Some Turbits are shell-crowned, but usually the head is smooth-crowned. It is generally believed that the smooth-crowned is the original variety, and is therefore to be preferred. Shell-crowns usually are from Germany. By Shield Turbits you doubtless mean the Shield Pigeon, a German Toy thought to be produced from a Turbit and some other Pigeon. The "Pigeon-Book," to be had at our office post free for twenty stamps, will give you full information concerning this Pigeon. The head of a Turbit should be very broad, the beak the shorter the better, and the eyes large and of a black or dark hazel colour.

Pigeons (*A Young Beginner*).—"The Pigeon Book," by Mr. Brent. You can have it free by post from our office if you enclose twenty postage stamps with your address.

Peerage (*H. M. S.*).—As you require a Baronetage, Knightage, and Parliamentary Guide as well, at a moderate price, you cannot do better than purchase Debrett's. It is in two portable volumes, and well illustrated.

Sprouted Wheat (*J. H.*).—It is perfectly good for fowls, either chickens or adults.

Ailanthus Silkworm Eggs (*H. J. O.*).—Write to Lady Dorothy Nevill, Dangstein, Petersfield, or to Mr. W. B. Jefferies, Ipswich.

Bees Condemned and Saved—Hives (*W. H. Steer*).—We are glad to learn that you have succeeded so well in saving condemned bees. They need not be fed so long as they possess a tolerable store of sealed food. If you mean to go in for scientific bee-keeping, you cannot do better than adopt the Woodbury frame hive. Your measurements are correct, but the frames should not fit tightly, and in practice we do not make the notches in which they rest quite three-eighths of an inch deep, whilst they slope a little, so that being shallower at bottom than at top the frames lift out more easily.

Artificial Swarms (*Idem*).—In making artificial swarms from common hives, we prefer using two stocks. No transfer into frame hives should take place until the stocks to be operated on become well populated. We should say towards the end of April or in the month of May, according to the strength of the colony.

POULTRY MARKET.—March 13th.

We have little change to note. Our supply is still small, and the trade but middling.

From observations taken near London during the last forty years, the average day temperature of the week is 50.9°; and its night temperature 32.9°. The greatest heat was 75°, on the 27th, 1830; and the lowest cold 14°, on the 25th, 1850. The greatest fall of rain was 0.60 inch.

HOTBED FOR CUTTINGS AND SEEDS.

IN fulfilment of a former promise, I now offer a few hints on the raising of plants from cuttings and seeds at this season, certain, from the number of inquiries, that such will be acceptable to many persons. My friends of the spade may consider any hints I may give as too late to be available for the present season, but I have well considered this matter, and find that amateurs generally have not the convenience to winter plants to afford cuttings early, have no means of accommodating early-struck cuttings so as to keep them slowly growing, nor, in fact, accommodation for more than one lot of cuttings and seeds. Those for whom I at present write cannot place the stock plants in heat to force for cuttings, but are to a great extent dependant on the season for the growth of the plants furnishing the cuttings. To advise any one to make up a bed in February for the propagation of plants from cuttings, while his accommodation for wintering the plants is confined to a structure from which frost is barely excluded, would be practically absurd, as the plants would not have grown sufficiently, and, besides, the cuttings so raised would require greater protection when struck than he could afford them. Hence they would become stunted, and instead of gaining time, the cuttings would be later than those put in a month further on, and receiving no check after being struck. It will, therefore, be perceived, that in the case which I shall endeavour to meet there do not exist the means for affording heat with the view of securing and striking early cuttings, but merely protection from frost. With such, however, late cuttings may be struck, and these very often make the finest plants.

By this time subjects which have had no more than protection from frost will have begun to grow, and cuttings may be taken from them with advantage to the plants, as these will become more bushy in consequence, and the cuttings put in now will by the end of May be good plants, blooming well in the summer.

For the purpose of raising cuttings and seeds at this time the bed need not be made so high as earlier in the season. A space 1 foot wider than the frame all round should be marked out, and a bed formed of hot sweetened stable dung, the dung and litter being well shaken out evenly, and beaten down with the back of the fork as the work proceeds. If leaves are at hand they may be used in the formation of the bed, mixing them with the stable manure as the work proceeds, and putting the litter on the sides of the bed. If the bed is of stable litter, a height of 2 feet 6 inches will be sufficient; if the bed is one-third leaves, it may be from 3 feet to 3 feet 6 inches in height according to the quality of the litter and leaves. To secure a steady heat the materials cannot be too well shaken out and beaten. This done put on the frame and lights, and within a week the bed will have heated, when the lights should be taken off, and, after levelling the surface, at 6 inches below this thrust in a stick as thick as the thumb till its point reach the centre of the bed. Draw out this stick daily, and if on holding it tightly in the hand it is not uncomfortably hot the time has arrived for making use of the bed, but if the heat be more than the hand can bear then the bed must not be used until the heat declines.

The bed being of a proper temperature—that is, if a ground thermometer with the bulb 6 inches in the fermenting materials indicates a heat of 90°, and not more than 100°, the operator must decide whether he will strike the cuttings in pots or pans, or in the soil that may be placed within the frame. For bedding Pelargoniums, I think it best to strike the cuttings in two-inch pots, an inch or two of sandy soil, sand, or even finely sifted coal ashes being placed over the surface of the bed, and then 3 inches of sawdust in which the pots are to be plunged to the rim.

Another plan is to cover the surface of the bed with strips of turf from a loamy pasture cut 2 inches thick and the same in width, and to make, at 2 inches apart along the centre of each, holes of about the same size as those formed by thrusting the finger into sand. The strips of turf are then to be placed close together, grass side downwards, on the bed, beginning at one end and proceeding until the area of the frame is covered. The next proceeding is to put in the cuttings, but before doing this it will be necessary to have ready sufficient silver sand to fill the holes in the turf, and a quantity of soil consisting of two-thirds light sandy loam and one-third leaf mould. If the loam is not sandy, then one-sixth of sand should be added to it. Drop the sand into the holes and introduce the cutting, resting its base on the sand; then fill up the hole with sand, and when a row of cuttings is inserted place from three-quarters of an inch to 1 inch of soil all over the turves and around the cuttings. In this manner proceed until the frame is filled. This plan will answer admirably for Pelargoniums, Calceolarias, Ageratums, and all bedding plants of strong growth, or of which the cuttings are of large size; but for Verbenas and Lobelias the turf should be cut into 1½-inch shreds, and holes should be made in them with a dibber at the same distance apart, and the cuttings inserted in the same way as for Pelargoniums.

If pots are used for the Pelargoniums, they should be filled with a compost of turfy loam two-thirds and leaf mould one-third, and a cutting inserted in the centre of each pot, filling up the space around the cuttings with silver sand.

After inserting the cuttings the lights should be drawn on close, the cuttings gently sprinkled overhead, and a thin mat thrown over the glass during bright sun. The sashes should be kept close, and a gentle sprinkling of tepid water given overhead if the cuttings flag and the surface of the bed appear dry, but do not overwater. The tem

perature of the frame should be 70°, or it may range from 65° to 80°. If there be an excess of steam the lights may be tilted or opened at back. Shade from bright sun must be afforded, and when the nights are frosty a double covering of mats over the lights will be necessary, care being taken that they do not hang over the bed, otherwise there will be danger of the frame being filled with rank steam from the dung. When the heat declines the frame should be covered with mats to preserve the proper temperature, litter being placed against the sides.

In a fortnight the Pelargoniums, Calceolarias, and Ageratums will have struck root, and the Verbenas and Lobelias will be well rooted in that time. In any case when the cuttings begin to grow air should be given—a little at first, increasing the quantity until it can be admitted early, or by 8 A.M., if the weather is mild, and it should be reduced to a minimum by 4 or 5 P.M., when by watering the plants overhead and shutting up close the temperature will be increased, and a moisture highly favourable to growth will be secured. The points of the cuttings, or rather plants, should be taken out after they have struck root, and this will cause the plants to become bushy and stiff. The soil is to be kept moist, but the sprinkling overhead will in most cases be sufficient. Continue this treatment until the end of the second week in May; then draw down the lights every day in mild weather after 7 A.M., and shut them up at night, but only to afford protection from frost. The plants being thus hardened-off should be planted out at the end of the month, or early in June, and this is easily done if they are in pots, but if in turf it is merely necessary to cut it between the plants in order to secure to each a small ball, and they do better thus than in any way I know.

As to striking the cuttings in pots or pans I do not recommend it for Pelargoniums at this season, though it may be done if the plants be potted off afterwards; but I do not consider that there is anything gained thereby. However, whether for Pelargoniums, Calceolarias, Ageratums, Verbenas, or Lobelias, the pots or pans should be well drained and the rougher parts of the compost placed at the bottom upon the crocks, afterwards filling to within half an inch of the rim with a mixture of turfy loam two-thirds, one-third leaf mould, and one-sixth sand, well incorporated, the pot or pan being surfaced with silver sand. Insert the cuttings, give a gentle watering, place in the frame, and plunge in the sawdust, the bed being covered with from 3 to 6 inches of that or some other loose material, or set the pots on a layer of sand an inch thick. The cuttings must have shade and a gentle watering overhead to keep the soil moist and the foliage fresh. They will be well rooted in a fortnight; then gradually harden them off. Set a frame on bricks under each corner, and place within it 6 inches deep of rough ashes, clinkers, brick rubbish, or better still, rough gravel; level and place thereon the riddlings of the following compost:—Light loam from rotted turves three-fourths, one-fourth leaf mould, and then 6 inches of sifted soil. Put on the lights and keep them close, and in a day or two the soil will have become warmed and aired; the rooted cuttings may then be planted out, not nearer than 1½ inch or 2 inches apart, but twice that distance should be allowed if there is room. After planting give a good watering with water of a temperature equal to that of the frame, and shut up the lights closely; keep them on continually, except when opened for watering, and protect with a mat in cold, frosty nights. Slight shade from bright sun will be beneficial for a few days until the plants begin to root and grow freely, then take out the points of the shoots, and give air by opening the sashes about an inch at back early in the morning, but on cold days keep them close, or admit less air, and about 2 or 3 P.M. water the plants overhead and shut up closely. Pursue this treatment, keeping them well but not immoderately watered until the middle of May, then harden off, and you will probably find autumn-struck plants cramped in pots over the winter and starved in spring not doing half so well when planted out as these, which should be moved and planted with a ball, giving a good watering after planting.—G. ABBEY.

VINES AND VINE BORDERS.

In an article under the above heading by "H. S.," in the Number for January 15th, the writer begins by criticising Mr. Wills's system of making Vine borders; then proceeds to find fault with him in no measured terms for not denouncing certain recommendations made by me as to the proper temperature for Vines at particular seasons of their growth in the treatise I wrote on the cultivation of the Grape Vine. It may appear superfluous that I should enter on any defence of a monograph, which is on the eve of entering on a fifth edition in as many years, nor would I have done so, were it not that "H. S." in the following passage imputes a motive—certainly a very ridiculous one—to Mr. Wills for his silence on the subject:—"Why has he [Mr. Wills] not already given utterance to his indignation at the barbarity of shutting up a Vine in the midseason of its growth in a mean temperature of 81° for Hamburghs, and 85° for Muscats? Mr. Wills must surely know that the temperature, in which 'proprietors of villa residences, who are not supposed to employ scientific gardeners' [a quotation from my work on the Vine], are recommended to grow them, is wholly unnecessary. Is Mr. Wills's silence to be attributed to the benefit he has received from the application of the author's styptic to the bottoms of his Pelargonium cuttings?"

Now, whatever benefit Mr. Wills's Pelargonium cuttings received from the application of the styptic in question it could not by any possibility influence him or his judgment in regard to the proper temperature in which to grow Grapes, nor prevent his giving public expression to it, however much it might differ from my recommendations on the same subject, seeing that we are perfect strangers to each other, and that he had no interest in the world, except the public good, in making known that he had used the styptic with advantage in propagating Pelargoniums—a discovery in which he certainly preceded me, though I have since verified it.

As to the barbarity of shutting-up Vines in temperatures varying from 81° to 85° of *sun* heat, all Grape-growers of any experience know that these temperatures are by no means the maxima at which it is perfectly safe and advantageous to shut up Vines in the afternoon, and that 100° with a moist atmosphere is perfectly safe; and if "H. S." had as extensive a knowledge of Grape-growing as he seems to have of geography, he would know this. Does he for a moment suppose that Grapes grown in the open air in the countries he refers to, can compare with the best Grapes grown in hothouses in this country? If he does, I challenge him to the proof, after which I shall be ready to admit that the temperatures I have recommended are too high, but not till then.

"H. S." says, "The Vine seems to be very much at home in the valley of the Volga, where the mean summer temperature is 72°." Does he mean to say that at certain hours of the day during some part of the Vine's season of growth the maximum temperature does not reach 90°? the maximum named by me.

In the autumn of 1861 I visited the Vine-growing part of Germany on the Rhine, where, on the sloping terraced banks of that river, the Vines, both root and branch, must, during some portions of the day, be subject to a higher temperature than anything I have recommended for hothouses; but in the absence of a continuation of this high temperature the Grapes are wretched subjects in comparison with the best English Grapes. My observations on the subject in Holland, Belgium, and France led me to the same conclusion—*i.e.*, that the temperature is not sufficiently high to produce first-class Grapes in the open air; and from all I know, founded on the observations of others, the zone referred to by "H. S." affords nothing in the way of Grapes equal to those produced by the aid of artificial heat.

I may remark that I was so struck with the inferior character of the Grapes in the hothouses I saw on the Continent, that I wrote home for three bunches of Muscats, to be sent to meet me in Paris, where I exhibited them at the first great Exhibition of the "Société Impériale et Centrale d'Horticulture" on the 17th of September, and though the three bunches only weighed 10 lbs., they created as great a sensation as if the sea serpent, or some other semi-fabulous monster, had made his appearance. They had the Emperor's gold medal awarded to them, and during three days that I paid a visit to the showrooms the table where they lay was so crowded that I never saw more of them, but left them to the disposal of a friend. On one occasion, when standing with a friend who understood French near the part where the Grapes were, I observed a French gentleman gesticulating very much, and making use of the word "Ecosse;" I asked my friend what he was saying about Scotland, and he replied, "Oh, he is saying that there must be some mistake, for there are no Grapes grown in the latitude of Scotland; in England there are." Now, this worthy Frenchman was, no doubt, well up in his geography, like "H. S.:" but not so in the history and practice of Grape-growing.

At the exhibition I have referred to there were hundreds of samples of Grapes from all parts of France. Few, if any of them exceeded 1 lb. in weight, and such Muscats as I saw there were green, not having been grown in a *sufficiently high temperature*. Those which I exhibited, though only such as are to be met with at our large metropolitan and provincial shows in this country every year, were, as compared with the bunches around them, like Tritons among minnows, both in bunch and berry, and for "H. S.'s" information, I may state that they were cut from the Vines that were, and still are, subject to the barbarous treatment he denounces.—Wm. Thomson, *Dalkeith Park*.

TOWN GARDENING.

(*Continued from page* 190.)

I must here observe, once for all, that I do not profess to give directions for the proper treatment or culture of each plant—that must be obtained by the inquiring reader from your Journal, or from other sources. I am too much in the dark myself as regards the science of horticulture to dogmatise on the subject. It is only here and there that I venture to offer such hints as are the result of actual experience. It will, however, be encouraging to some to know that I had no greenhouse, and that mine was all out-door work, simple plain-saling, as it were.

To return to perennial plants. Auriculas generally do well, but they require renewing after a few years, and change of position. No renewal of soil will do: they decay at the junction of the offshoots with the main stem, and break off. The Polyanthus likewise will grow, but can hardly be said to flourish. The chief difficulty with which I had to contend was the foliage drying up and withering in the summer, to obviate which I used to sow around the plants early in the spring Virginiau Stock, or some other quick-growing annual, which shaded the plant from the sun and generally preserved it. Œnothera taraxacifolia, a bright yellow flower, low and spreading, does well; and I may mention, though out of place, being a biennial, the well-known Eveniug Primrose (Œnothera biennis), which rarely flowers in the first year. It commonly grew to the height of 4 or 5 feet near the walls, and its fragrance is delightful on a still summer's evening; but it has its defects, it scatters its seed all over the beds, and becomes a weed unless well watched and only a few plants are permitted to grow.

The small dwarf Campanula, blue and white; Arabis albida; the Aubrietia; the Fraxinella, red and white; and Saxifraga carnosa [?] all do well and increase. There is a perennial Hawkweed and a perennial Coreopsis, both of which increase; the former is a showy rich brown and yellow flower, the Coreopsis is poor. Fuchsias, the old sorts more especially, flower well, and stand the winter when well established, bnt they require to be cut down in the spring. Potentillas generally do not flourish, but the Geums succeed tolerably well. Aster alpinus, a dwarf perennial, with pretty mauve petals and a yellow centre, does well and increases, and is always admired. Gentiana acaulis, or Gentianella, grows well, looks healthy, and increases by division of the roots; but its beautiful deep blue flowers never appear, not even a bud. On the other hand, King's or Catesby's Gentian grows poor and wiry, looking unhealthy, but flowers freely, both the blue and the white. The Spiderwort (Tradescantia), all colours, but chiefly the purple with golden eye, is a valuable plant, but must be occasionally divided; for if suffered to grow too large, the outer stems become flaccid and trail on the earth, and if tied up to prevent this, the central flowers rot, after rain or watering, and do not come to perfection.

The Lily of the Valley is likewise most useful and agreeable. It will grow at the roots of Lilacs and in corners where nothing else will succeed, the only care required being to prevent its twitch-like roots from roving among plants where they are not wanted. The little yellow and fragrant flower called Musk has likewise a twitch root, and though it dies down in winter, it will live and spring up again the followiug summer. It requires a moist soil, or good watering. Pinks will languish for a year or two, Carnations rather longer, but both require to be renewed. Some of the Indian Pinks, however, succeed better; and I was much surprised on sowing, rather hopelessly, the seed of the pretty little wild Pink (Dianthus deltoides), which grows in the neighbourhood, to find that it was green and healthy during the first year, and the second it flowered well, a mass of bloom, but did not seed.

I must not omit the Clematis integrifolia, bearing a handsome velvety flower of purple and cream colour. I grew this in long iron baskets about 3½ feet in height out of the ground, and it never failed during the whole term of my residence. I had a species of Scabious which likewise continued throughout the same period. I do not remember its name; its leaves grow somewhat like those of the Pine Strawberry, and its flowers are first of a greenish white, and become pink when matured. The London Pride must not be overlooked, which probably has its name from its prospering so well amid smoke and soot; and the blue Cornflower is also useful for variety.

I must now notice a few that will *not* succeed. Money and labour are thrown away in the attempt to cultivate Roses in smoke; they must have pure fresh air. I have tried all sorts, and have bought the dwarfer kinds in pots, and plunged them whilst flowering, only to see the remaining buds refuse to open. The Chinese sorts are the best, if kept well watered and cut in; but these rarely survive the season, and then only to betray melancholy symptoms of decline. I must not, however, omit to state that I have seen in the same town, on the outside of a house much exposed to smoke, a Banksian Rose, which for several years blossomed well, and then decayed and died. Pæonies, Hepaticas, and Pansies will not respond to coaxing. The latter if purchased and planted in the spring will throw out flowers throughout the season charily and diminishing in size; if they survive the winter they degenerate into the smallest Heartsease and fill the beds with seeds. Violets do no better. Garden Daisies immediately begin to degenerate to the common field sorts. Antirrhinums, Columbines, and Salvias make but a poor figure, and will not increase. The Helleborus niger, or Christmas Rose, declines and dies in a season or two. The Phlox tribe will flower during one season, but rarely the next; if they do, it is only to exhibit a few miserable buds. The plant itself will continue for several years, but in a declining state. It is the same with the Delphinium family. I may here state that when I succeeded to the garden I found in it a a plant which, every year for twenty years, continued to grow in great vigour and health to the height of from 3 to 4 feet, according to the season, but never flowered; once or twice there was a slight indication of buds forming in the autumn, but they never came forward. I concluded it to be one of the larger species of Phlox; but, on removing a portion of it into the country, to my surprise it proved to be a fine purple Michaelmas Daisy with a yellow centre. A variety of the ordinary Michaelmas Daisy, which flowers in August, always did well in the smoke; so did a small bushy sort, with flowers not larger than a silver penny, but the remaining sorts did not succeed.

I next proceed to mention bulbous plants. The whole of the Lily tribe will generally thrive, but more especially the large Orange and the White, and they plentifully increase. There is an early orange Lily, also, growing only about 1 or 1½ foot in height, which does well, but does not throw off fresh bulbs so profusely as the larger sort. Lilium lancifolium roseum and splendens succeed, and may be left in the ground all the winter, being perfectly hardy; but in this case the leaves, though they push up with great vigour in the spring, begin to decay before the flower is fully developed. The Turncap Lily, though it grows well, never, or very rarely, puts out a flower; the Crown Imperial is nearly as shy, and the Tigridia pavonia still more so. In the instance of the Crown Imperial it need not be regretted, for the foxy disagreeable odour from the bulb more than counterbalances, in a small and confined garden, any pleasure to be derived from looking at the plant. Hyacinths, Tulips, Cyclamens, most kinds of Iris, and the commoner sorts of Gladiolus, succeed well, the latter, however, requiring some care. Aconitum napellus, so named from the tubers resembling little Turnips, is a delicate and elegant species of Monkshood, and flourishes in smoke under trees or anywhere. I am sorry that I cannot include the Anemone and Ranunculus in this list: there is, however, the common Globe Ranunculus which answers pretty well; and there is a valuable autumnal Anemone, from Japan, growing 1½ to 2 feet high, with a good flower in two varieties, rose and white, but this also requires watching, for it spreads itself in an unaccountable manner. It is neither bulbous nor tuberous, and should be purchased in the plant. Narcissi and Jonquils languish for years, becoming more and more attenuated, but produce no flowers. So likewise the family of Muscari Hyacinths (the Feathered, the Tasselled, the Grape), dwindle in like manner. Neither Snowdrops nor Crocuses do well; the Yellow Crocus is the best; but of these the mice eat the bulbs, and of those which escape, the sparrows peck out the buds to get at the saffron, and litter the flowers about. I have often been angry

with these feathered depredators in the country, when a few modest Primroses have ventured to show themselves, to see them speedily nipped off and strewed upon the ground. Their dust-baths, also, which they are so fond of taking in dry weather, are an awful nuisance, spoiling the surface of the newly-raked beds, and often exposing the roots of plants to destruction. I remedied this, however, in some measure by placing garden-pot saucers filled with water on the spots which they attacked, which the generality preferred; but a few of the old school, bigotted to their ancient ways, still took to the dust, delighting to half bury themselves in it, as a hen does, and to lie basking in the sun. Watering the bed well at the top will prevent this, but it is not always expedient to do so in the morning of a hot day, as it scorches the plants.

Annuals next invite attention. Marigolds, Asters, and Stocks all do well, but I should advise that they be purchased always of the gardeners at the season when they are brought into the markets in bunches for planting out. A penny will buy a dozen, and they are but precarious if raised from seed. The German and French Asters should be purchased in pots just when first putting forth their flowers. They last well, and are very handsome. Lobelia gracilis and Nemophila are also safest if bought in pots, and transferred to the earth. The Lychnis does best if bought in the plant, and with care, cutting the stems down to the roots after flowering, is almost perennial, certainly the scarlet variety will last for three or four years. Convolvulus major and minor, Nasturtium (now termed Tropæolum), Mignonette, Virginian Stock, Clarkia, Godetia, Sweet Sultan, Sweet Pea, Sweet William, Erysimum Peroffskianum, Wallflowers, Zinnias, and Canterbury Bells, purple and white, also succeed. This list might be considerably added to, I have no doubt, but it contains what were abundantly sufficient for my wants, and I only occasionally tried others. Having no space to spare in my miniature garden, I used to sow or plant annuals among and closely around those bulbs which flower in the earlier part of the year, and they were ready in their places when it was time to cut down the decaying leaves of the bulbs.

Of those annuals which will not succeed, I may just mention the pretty scarlet Linum, which I have tried both from seed and by purchasing plants, but it would not be persuaded. Lupins of all sorts I consider a failure, the larger and smaller blue and the rose Lupin especially. The common yellow sometimes put out a few miserable spikes, both in form and colour, so I discarded them. I must except, however, one of the perennial kinds, Lupinus Moritzianus, which does tolerably for two or three years. The Silenes and the Eutocas fail; so, also, do the Gilias, Limnanthes, Lasthenias, Cenias, Monolopias, Schizopetalons, and many others, which I consider only as rubbish in any garden, whether in town or country.

Most of the usual bedding plants will run their summer course satisfactorily, though some better than others. Verbenas mostly do well, the scarlet and the white the best; the former will often stand the winter. All the Pelargoniums succeed, especially the old scarlet. They continue in flower for four or five months, till the frosts cut them down. Latterly instead of throwing them away I used to anticipate the frosts, and in October gave them away among the working men of the town, who nursed them in windows and considered them great prizes. Cinerarias, though pretty while they last, I discarded because they were so soon over, and left only unseemly stumps. For the same reason I did not care for the generality of Calceolarias; but the bright yellow herbaceous sorts are admirable, keeping up a gay appearance throughout the season by simply taking care to cut off the stalks as soon as the heads of buds have dropped their little slippers. Petunias do not relish smoke; as soon as they are brought under its influence the flowers begin to dwindle. I purchased a magnificent plant in full flower of the Double White variety, took it with its ball of earth out of the pot, and plunged it in one of the best situations in a border. The plant continued to look healthy throughout the summer, and buds showed themselves profusely; but the flowers, which at first were the size of a florin, soon dwindled to that of a shilling, then to that of a sixpence, after which they refused to open, and when the frosts came it had at the least a hundred buds upon it not larger than a pin's head. Ageratums, Heliotropes, Pentstemons, and Cupheas all do tolerably; but the last-named make but little growth.

If the reader should be ambitious of a rockery he will find several of the plants already named of a dwarf character succeed upon it, to which may be added the common Bracken Fern, which dies down in the winter, but puts up its fronds again in the spring; the Gazania, which largely increases, apparently unconscious of smoke, sometimes surviving the winter; and, for the season, most species of the Mesembryanthemum. Nor should I omit to state that, if vegetables are desired, Rhubarb and the Jerusalem Artichoke will thrive. I planted them in a very narrow border at the south end under the dwarf wall, and though they had but little sun they yielded well.—Philokepos.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

March 19th.

First Spring Show.—A heavy sky, a keen northerly wind, drifts of snow, slush under foot, and then a close drizzle—such was the character of Tuesday last, when the first Spring Show of the season took place; but though the weather was about the worst that could have been, not so was the Exhibition, for take it all in all, it was one of the finest which have been seen at South Kensington so early in the season, and that season, too, one of the most unfavourable that could well have happened for the development of the fine productions which were exhibited. These productions were a triumph of horticultural skill, and a proud evidence of what our horticulturists can do in contending with adverse circumstances of climate; for to attain such perfection in cultivation requires years of experience, and to shew flowers as they were shown on this occasion months of unremitting attention, and at last no small degree of courage to expose them in such a day. The Fellows of the Society ought to feel much indebted to the numerous exhibitors for the support which was so heartily afforded under such trying circumstances, and that that support was most fully and generally appreciated we have every reason to believe; indeed, had there been an opportunity, some expression, we understand, would have been given to the feeling entertained on the subject by the Council.

Hyacinths formed the most important feature of the Show, the principal exhibitor being Mr. William Paul, of Waltham Cross, who was far in advance of any other in the size and beauty of the noble spikes which he placed in competition. It would be difficult to say more in their praise than that they were quite equal to those which he exhibited last year, and were remarkable for the same vigour and the same freshness of colour. In the class for eighteen he was first with magnificent spikes of King of the Blues, Princess Mary of Cambridge, and Blondin (new), much paler in colour than the preceding, and broader in the petal; Charles Dickens, Van Speyk, Baron Von Tuyll, all three very fine; General Havelock and Feruck Khan, two varieties closely approaching to black, and both very good; Solfaterre, Koh-i-Noor, Macaulay, Vunxbauk, all excellent, the latter large and very compact in spike, but scarcely so brilliant in colour as last year; Prince Albert Victor, a new and very fine purplish crimson with lighter edges; a splendid spike of Sir Henry Havelock, Grandeur à Merveille, Snowball, a fine spike for that kind, Mont Blanc, and La Grandesse, a large pure white. Messrs. Cutbush, of Highgate, were second with an excellent collection, though the spikes were scarcely so fine as those which they usually exhibit, and which have given them so well-deserved a reputation in connection with this flower. The sorts were Baron Von Tuyll, Charles Dickens, Grand Lilas, General Havelock, Cavaignac, Von Schiller, fine colour; Gigantea, Princess Clothilde, Florence Nightingale, immense spike; Le Prophète, Grand Vainqueur, Macaulay, Duc de Malakoff, Mrs. James Cutbush, Mont Blanc, Snowball, Princess Helena, like the preceding three, a very good white, and Haydn, a beautiful mauve. Mr. J. Kirtland, Albion Nursery, Stoke Newington, and Mr. William Cuthush, of Barnet, were equal third with collections containing good examples of Von Schiller, Sultan's Favourite, Charles Dickens, Grand Lilas, Baron Von Tuyll, Orondates, Mimosa, Argus, Queen of the Netherlands, Maria Catharina, fine in colour though not large in spike, and Ida, yellow.

In the Amateurs' Class for twelve Hyacinths, of six kinds, Mr. Bartlett, Shaftesbury Road, Hammersmith, had a third prize; and in the open class for six kinds Mr. W. Paul was first with splendid examples of Grandeur à Merveille, Prince Albert, Macanlay, King of the Blues, a magnificent spike; Lord Cowley, pale porcelain, fine spike, large bells; and Victor Emmanuel, pale crimson, striped with deeper crimson. Mr. W. Cutbush, of Barnet, was second with very good examples of General Havelock, Macaulay, Mont Blanc, Couronne de Celle, remarkable for its beautiful azure colour; Alba Maxima, and Von Schiller, the last very fine. Mr. Kirtland, who was third, had the same variety and Macaulay very good.

Hyacinths grown in pots and glasses in windows were not as a whole so good as could be desired. Some very good specimens in 48-pots from Mr. Beach, gardener to C. J. Herries, Esq., Sevenoaks, were awarded a first prize, and Mr. Bartlett, of Hammersmith, was second with fair but rather unequally grown spikes in 32-sized pots. For Hyacinths in glasses Mr. Rumsey, Waltham Cross, had a first and Mr. Beach a third prize. It may be remarked that Charles Dickens was shown both in glasses and in pots better than most of the other varieties.

In the class for six Hyacinths, new kinds of 1866-67, the only exhibitor was Mr. William Paul, who had a first prize for Bird of Paradise, Linnæus, Sir Henry Havelock, Blondin, Lord Shaftesbury,

and Prince Albert Victor, which will be noticed more particularly in our Floral Committee report.

In addition to his other fine collections Mr. W. Paul exhibited in the Miscellaneous class upwards of a hundred pots, and received an extra prize. Among the Blues were splendid examples of Argus, King of the Blues, Baron Von Tuyll, Couronne de Celle, Grand Lilas, Blondin, Leonidas, and Bleu Aimable; of the nearly Black kinds, Feruck Khan and Prince Albert; of Whites, Mont Blanc, Snowball, and Alba Maxima; Reds, Von Schiller, Howard, Garibaldi, Princess Clothilde, Macaulay, Duc de Malakoff, buff striped with red; Haydn, mauve; and Ida and Bird of Paradise, yellow. For this collection an extra prize was given.

Narcissuses were not very numerously shown. Messrs. Cutbush were first with Bazelman Major and Lord Canning, white, with a yellow cup, both fine large flowers; Cleopatra, with an orange cup; and in the same way, but with smaller flowers, Jocrisse, Parfaite, and Regulus. Mr. Bartlett was second with, among others, Grand Monarque and Gloriosa, the latter a fine white, with a deep yellow cup. Mr. W. Paul had an extra prize for a numerous and fine collection in the Miscellaneous class.

Tulips, though the day was too dull for them to be seen in their full beauty, yet made a fine display. Mr. W. Paul was first for twelve pots of six kinds, these being Proserpine, violet shaded rose; Keizerskroon, deep red, edged with yellow; Couleur Cardinal, deep scarlet shaded with violet, small but effective; Fabiola, rosy purple and white; White Pottebakker, and Van der Neer, violet shaded rose. Messrs. Cutbush were second with Tournesol, Vermilion Brilliant, Couleur Cardinal, Globe de Rigaud; and Duke of York, red edged with cream white. A similar prize was awarded to Mr. Burley, nurseryman, Bayswater, for a collection containing several varieties stated to be new, among which, Queen, white feathered with crimson, and Bride, crimson and white, were very pleasing.

In the Amateurs' Class for twelve pots, four kinds, Mr. Bartlett was first with Keizerskroon, Vermilion Brilliant, White Pottebakker, and Globe de Rigaud. A fine collection of about one hundred, from Mr. W. Paul, received an extra prize.

Cyclamens, especially the large and beautiful collection from Messrs. E. G. Henderson, formed one of the most effective features of the Show. Very good collections, though not so numerous, were furnished by Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, and others. For six, Mr. Wiggins was first; and Mr. Fairbairn, Sion; Mr. Todman, gardener to R. Hudson, Esq., Clapham Common; and Mr. Butter, gardener to B. Hooke, Esq., Fulham, equal third; whilst for collections not limited as regards number, Messrs. E. G. Henderson were first, Mr. Wiggins second, and Mr. Todman third.

Crocuses.—A beautiful collection was furnished by Mr. Wm. Paul, and received the first prize in the Nurserymen's Class. The varieties most noticeable for their beauty were Sir Walter Scott, a fine large flower, lilac striped with white; Cloth of Silver; Mammoth, large-flowered white; Princess of Wales, a fine pure white; Princess Alexandra, white, pencilled with purple; Prince of Wales, bluish violet; David Rizzio, and Sir John Franklin, purple; and Golden Yellow. Mr. Bartlett, of Hammersmith, had a first prize in the Amateurs' Class with good examples of Albion, Sir W. Scott, Victoria, and other kinds.

Chinese Primulas likewise afforded a fine display, and were almost without exception excellent. For six plants, Mr. Wiggins was first, Mr. Fairbairn second, Mr. Todman third; and for three, Mr. Wiggins was first, Mr. Todman second, and Mr. Fairbairn third.

Lily of the Valley.—Finer examples of this flower have probably never been exhibited than the six pots shown by Mr. Howard, gardener to J. Brand, Esq., Balham, and to which the first prize was awarded. The foliage was equally ornamental with the flowers, which were large and of a beautifully pure white. Mr. W. Paul's pots, to which the second prize was awarded, contained a great profusion of bloom, but the bells though more numerous were not so large. Mr. Todman, Mr. Cuthush, of Barnet, and Mr. Bartlett also received prizes.

Camellias, Forced Shrubs, &c.—Mr. W. Paul received a first prize for a box of Camellia blooms containing excellent examples of Ochroleuca and Fimbriata, white; Eximia, Mathotiana, and Belle Jeannette, red; Lavinia Maggi, Prince de Canino, and Princesse Clothilde, carnation-striped; and La Reine, delicate pink. Mr. Todman, who had also good blooms, was second. For four plants in flower, Mr. Bull, who was the only exhibitor, received a first prize for Valtevaredo, Anna Frost, Tentonia rosea, and another; and a similar award was made to him for a single specimen of Princess Bacchiochi, which, though good, was not so fully in bloom as desirable.

Of forced shrubs the best six came from Mr. W. Paul, who had a fine specimen of the fragrant white-flowered Raphiolepis ovata, the variegated Weigela rosea, and Rhododendron Schilleri, both in fine bloom, Deutzia gracilis, Double Pink Thorn, and lastly a half standard Genista purgans, worked on the Laburnum, with its head one mass of yellow flowers. Mr. Bartlett was second with Kalmia latifolia, a white variety of Rhododendron catawbiense in profuse bloom, Rhododendron Everestianum, Deutzia, and Yellow Ghent Azalea.

In Miscellaneous collections of plants in flower, the first prize was awarded to a numerous one from Mr. Bull, containing six beautiful specimens of the charming Odontogloasum Alexandræ, the brown-apotted O. gloriosum and maculatum, a variety of Phajus grandifolius having the leaves very distinctly striped with cream yellow, several Lycastes, Cypripediums Dayanum, Lowii, hirsutissimum, and concolor, Phalænopsis Schilleriana, Rudgea leucocephala alluded to farther on, the showy Imantophyllum miniatum, variegated Selaginella denticulata, Palms, Dracænas, fruiting Orange trees, variegated Euonymus, several plants of the small white-flowered Rhododendron virgatum, and various Aucubas in flower and fruit, of which the common variegated covered with fine berries and standing about 4 feet high received and well deserved an extra prize. Mr. W. Cutbush, of Barnet, took the second prize with a small well-bloomed collection, containing Tetratheca ericæfolia, Boronia pinnata, Cinerarias, Cytisus racemosus, Mignonette, and fruiting Aucubas; and Mr. Bartlett was third with Azalea amœna, Cinerarias, Hyacinths, Tulips, &c.

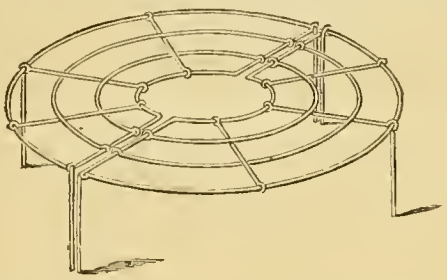
Among miscellaneous subjects were beautiful collections of Roses in pots from Mr. W. Paul and Messrs. Paul & Son, to both of whom extra prizes were awarded. The plants from Mr. W. Paul were remarkable for their fine large foliage, and were, besides, in excellent bloom for the season, especially Madame Victor Verdier, President, Paul Delameilleray, Alba Rosa, Le Rhone, and Madame Willermoz. Messrs. Paul & Son's plants were likewise very good, and some of them were blooming very freely, especially Princess Mary of Cambridge, Lord Raglan, Gloire de Dijon, Devoniensis, Souvenir d'Elise, Maurice Bernardin, and Anna Alexieff were the most noticeable of the others. Mr. W. Paul contributed, besides, several boxes of cut Roses, many of which were excellent; among them were fine buds of Maréchal Niel, Narcisse, Safrano, and Madame Falcot. Pierre Notting was remarkable for its fine, violet-shaded, deep red colour, and that old favourite, Gloire de Dijon, was also fine. Mr. Bartlett, besides wire-baskets filled with Hyacinths and Tulips, had a highly creditable set of Filmy Ferns, for which he received an extra prize; and a similar award was made to Mr. Todman for Azaleas, and to Mr. W. Cutbush for half-a-dozen pots of Mignonette trained so as to form pyramids from 18 inches to 2 feet high, and about 18 inches in diameter at the base.

Sub-Floral Committee.—An unusual number of interesting plants were brought before the Committee at this first spring Show. It is seldom in the height of summer that so many certificates are awarded, and for such choice plants. Mr. Shenton, Biggleswade, Beds., sent small specimens of a seedling Retinospora, golden variety, the plants much too young for any judgment as to their merits. Messrs. F. & A. Smith, Dulwich, sent seedling Azalea Hector, very dark red, upper petals spotted; the flowers dull in appearance. It received a commendation. From the same firm came also a collection of golden Zonal Pelargoniums, not in season for displaying their merits, and which should be seen again. Mr. G. Fairbairn, gardener to the Duke of Northumberland, Sion Gardens, sent a seedling Cineraria Duke of Northumberland, deep ruby-coloured ray florets, too long for an exhibition flower. It was commended as a decorative variety. Messrs. E. G. Henderson exhibited a nice plant of Rudgea leucocephala, also shown by Mr. Bull under the name of Psychotria macrophylla, the former being the correct name. This is a plant of great beauty, and was described last year. Mr. Bull sent Aucuba japonica macrodontha mascula; Aralia spathulata, a very curious and beautiful-foliaged plant, with long, linear, toothed foliage—first-class certificate; Aralia crassifolia, dark green, also distinct—first-class certificate; Agave macrocantha, a curious new form of this section of plants, the short thick leaves furnished with sharp teeth, pointed with a sharp needle-like spine—first-class certificate; Imantophyllum miniatum superbum, much like I. miniatum, so much so that the difference of the flowers as to colour was not perceptible. Messrs. E. G. Henderson received a special certificate for six seedling tricolor Pelargoniums, which the Committee hope to see again at the proper season—Mrs. Grove, Caroline Longfield, Anna Paget, Tamworth Pet, and Emma Cheere were very promising varieties. Pyrethrum Golden Feather was sent by the same exhibitors, but not in a condition at this early season of the year to display its merits as a bedding plant. Mr. W. Cruickshanks, gardener to W. Jones Loyd, Esq., Langleybury, Watford, received a special certificate for a box containing twelve trusses of his seedling Verbena Lady of Langleybury, a pale lilac-striped variety, which was awarded a first-class certificate last summer—a very promising, useful, bedding plant. Mr. Preece, gardener to E. Wood, Esq., Acton, exhibited seedling Zonal Pelargonium Hanger Hill Gem, a flower without any merit. It is much to be regretted that exhibitors should send seedlings so completely out of their season. Messrs. Veitch exhibited a new Orchid not named, probably a Mormodes—a second-class certificate was awarded, it being distinct from others; also Hippeastrum pardinum, a beautiful spotted form of this superb flower, which was awarded a first-class certificate: this was very distinct from any other Hippeastrum ever seen. Mr. Cannell, of Woolwich, exhibited for Mr. Bennett, of Osberton Hall Gardens, a few flowers of a Pansy of the Viola cornuta strain, pure yellow, said to be constantly in blossom, and a very decorative flower.

Mr. William Paul exhibited several new Hyacinths, all of them of first-rate quality. It is impossible to describe the magnificence of Mr. Paul's collection. The spikes of flowers were grand and better than ever before exhibited by him. Lord Shafteshury, a very large single white bell, loose spike, received a first-class certificate; also Blondin, light grey, single flower, compact spike, very beautiful—first-class certificate; Prince Albert Victor, a dark purplish red single

flower of great beauty—first-class certificate; Linnæus, a brilliant deep single rose flower—second-class certificate, one of the brightest varieties grown, the flowers of the spike not quite in perfection; Vunxhaak, a fiery red flower, which was awarded a first-class certificate last year; also Bird of Paradise, which was equally noticed; both continue to maintain their character. It is not our duty to notice the several varieties, but we must add, never were such fine specimens exhibited before; and we hope to see them in their special colours and merits duly noticed. Mr. Paul also exhibited a standard plant of Nosegay Pelargonium Dr. Hogg, deeper in colour than that great favourite Amy Hogg; but at this early season it is impossible to risk any decision on the merits of Zonals. Justice cannot be done to the plant nor to the judgment of the Committee.

Fruit Committee.—Mr. Johnson, gardener to the Marquis of Ailesbury, Sevenoaks, sent Lady Downe's Grape in excellent condition as a proof of its superiority over Ahbee, shown at the last Meeting; and Mr. Holliday, gardener to H. B. Walmsley, Esq., Acton, a very good fruit of the Ripley Queen Pine, apparently upwards of 3 lbs. in weight. For this a special certificate was awarded. Mr. Lydiard, Batheaston, sent Asparagus, and from Mr. Budd came a Cucumber, the result of a cross between Telegraph and Munro's Prolific, like the Sion House, but rather more prickly. James's Long-keeping and Brown Spanish Onions from Mr. Whiting, The Deepdene, and that called Nuneham Park, from Messrs. Cutbush, were also placed on the table to show their keeping properties. Mr. R Holliday, 2A, Portobello Terrace, Notting Hill, exhibited a contrivance called "Paxton's Strawberry Crinoline," consisting of a circular table of



galvanised wire, as in the accompanying engraving, made in halves to put round the plants, in order to prevent the berries coming in contact with the ground. The cost was stated to be £5 5s. per gross. The Committee, however, considered that though the contrivance might be useful to amateurs, yet the cost would prevent its being employed where Strawberries are grown on an extensive scale.

General Meeting.—G. F. Wilson, Esq., F.R.S., in the chair. The business of the meeting was purely of a formal character, and after the election of fourteen new Fellows and the admission of the Worksop Floral and Horticultural Society into union, the Chairman announced that in consequence of the small attendance the lecture, which was to have been given by Mr. W. Paul, would be deferred till Tuesday, the 26th inst., at 3 P.M.

SIZE AND SEPARATION OF GEOMETRICAL FLOWER-BEDS.

I purpose forming one or two groups of geometrically arranged flower-beds—about nine beds in each group. I think I have somewhere seen a remark, that the size of flower-beds should be determined by the distance one can reach over the bed without placing the foot on the bed. I can reach about 2 feet, so presume that no part of a bed should be more than 2 feet distant from a walk.

I should also be glad to know how far apart the flower-beds in the before-mentioned groups should be, so that without interfering with the harmonious blending of the different colours in the beds viewed as a whole, there would still be sufficient space between the beds. I should, perhaps, mention that I intend having them edged with Box, and gravel walks between.—C.

[As you can reach 2 feet, beds of 4 feet in diameter would suit you; but we presume that the rule about reaching was made with the understanding that one foot was placed on the bed. By this means you could extend your hand 2 feet more, and, therefore, your beds might be from 4 to 8 feet in width. By having only one foot on the bed and one on the walk, you can clean the foot from the bed before placing it on the walk if anything from the bed should adhere to it; and, removing the mark of the foot, the bed will retain no trace of your visit. If on grass, in such geometrical groups, and the beds are 4 feet or more in width, the paths should be from 3½ to 4 feet wide. On gravel, if the beds are 4 feet, wide the paths might be 3 feet or even less, but we believe in most cases 4 feet would be more satisfactory.]

GREEN TURF FOR CAMELLIAS.

I have great pleasure in adding my testimony to the value of fresh turf for Camellias. I have used it for the last five years, and my plants never looked so well as they do now. I hope more of your readers may, after reading Mr. Pearson's recommendations, be induced to give it a trial.

In one respect, perhaps not essential, my practice has differed a little from Mr. Pearson's. Before using the turf I place it grass side downwards on a flue, not long enough to dry the soil to dust, but merely to char the blade sufficiently to kill any insects' eggs, &c., that may have been deposited there. In two or three days after potting I give the plants a thorough watering with lime water.—H. F. B.

PROTECTIVE POWER OF AN ORCHARD HOUSE.

My object in writing is to point out the protective power of an orchard-house. When the open air temperature during the severe frost of January was about zero, the thermometer in the orchard-house never fell below 20°, so this was better than Cornwall, where it went down to 15°. Of course, the snow-covered roof, and the short duration of the frost, assisted the orchard-house. Many things in pots placed on the borders, covered with bell-glasses, and these with straw and mats, passed through the ordeal uninjured. The shoots of Figs in pots, with straw round their roots, but unprotected above, are quite green, while against a building, though covered with two or three mats, the extremities seem killed back.—G. S.

WHAT SHRUBS AND TREES ARE NOT INJURED BY GAME?

"E. F. G." asks for some information on this point; I have, unfortunately, a sad experience in such matters, and have given great attention to the subject. In a hard winter like the last, I may say the present, for we have here now, March 12th, heavy snow falling, and 8° of frost, all shrubs and young trees have suffered dreadfully from hares and rabbits. My place is in a valley, and the starved-out mountain hares visited me every night in droves. Large drifts of snow several yards high enabled them to make their way into every place to which they should not have had access, and they climbed up the espaliers, and wall fruit trees like cats. This has also happened in many town nursery grounds, and immense damage has been done.

I hardly know what shrubs suffer least. "E. F. G." is perfectly correct in stating that hares and rabbits will attack a newly-planted clump or isolated bush, no matter what it is, and the smaller it is the more sure is it to be visited and destroyed. I watched my shrubberies and made notes every morning, and found that as in former severe winters, Hollies went first, then Laburnums and Broom. They also ate odd Rhododendrons, and Berberis aquifolium, but not to any considerable extent when in a mass, or when the bushes were of a good size, and dense. It is the bark they want, not the leaves. It is rather odd that hares, in particular, are so fond of Yew and Laburnum, two very poisonous trees. They must take it as a medicine, as we use calomel, &c., to digest other things.

With regard to the Fir tribe, I have invariably found that the Pines go first, then Larch, then the Abies class. I have lost every Scotch Fir and Austrian Pine which has been planted for the last two or three seasons. The Norway Spruce, Silver Spruce, and Balm of Gilead, are merely nibbled, and may come round; but many Scotch Firs 6 feet high are peeled entirely, and hopelessly destroyed.

Allow me to recommend "E. F. G.," when forming a new plantation, to gather his Laburnum seeds, and either sow them broadcast in the woods, or, which is better, raise as many seedling plants in his nursery garden as he can, and plant them for underwood. This will afford food in hard weather, and hares, &c., will touch nothing else as long as any are left; when eaten off the plants come up again next season. Ash is a favourite food also, and I have seen a cartload of Ash tops thoroughly

peeled in a night. I have preserved my young woods to a great extent by throwing down heaps of Ash tops and thinnings in the fields adjoining the coverts; hares like Crabs and the Apple tribe better still. In hard weather I should advise the snow-plough to be used when requisite, and to throw Turnips or Cabbages on the bare part.

In 1860-61 hares ate nearly all my Araucarias. This season, though the frost was more severe, but of not so long duration, Araucarias, Deodars, Cupressus Lawsoniana, Hemlock Spruce, &c., have hitherto escaped; but, perhaps, this is because they had become good-sized specimens, and the bole or main stem was not a salient object.

As "E. F. G." suggests, the difficulty under such circumstances, is to have young plants well established. If we can get three or four years over, we may hope for success. My advice is to plant plenty of undergrowth in young woods, and have as much Broom as possible about the neighbouring banks and hedges, so as to entice the game away from more valuable food. I once saved a plot of young Pines by dragging their tops through the liquid manure hole before planting. This may be renewed in a small home plantation.—Jackson Gillbanks, *Cumberland.*

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Pleroma sarmentosa.—(Sarmentose Pleroma).—*Nat. ord.*, Melastomaceæ. *Linn.*, Decandria Monogynia. Native of cool valleys near Cuenca, in Peru, and at elevations of 8000 feet. A great acquisition to our greenhouses, being much more beautiful than P. monochætum. Flowers violet. — (*Bot. Mag.*, *t.* 5629.)

Sarcanthus erinaceus (Hairy-stemmed Sarcanthus).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Probably a native of Moulmein, being introduced by the Rev. Mr. Parish. Flowers white tinted with pink.—(*Ibid.*, *t.* 5630.)

Siphocampylus Humboldtianus (Humboldt's Siphocampylus). —*Nat. ord.*, Lobeliaceæ. *Linn.*, Pentandria Monogynia. Native of Peru. Introduced by Mr. Bull, Chelsea. Very ornamental in a warm greenhouse. Flowers scarlet, with purple stamens protruding.—(*Ibid.*, *t.* 5631.)

Oncidium serratum (Saw-toothed Oncid).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monogynia. Native of Peru, and thrives under moderately cool treatment. Flowers chocolate-brown, edged with yellow.—(*Ibid.*, *t.* 5632.)

Synadenium Grantii (Capt. Grant's Milkbush).—*Nat. ord.*, Euphorbiaceæ. *Linn.*, Monœcia Monandria. Among the dried specimens collected by Captains Speke and Grant in their exploring visit to the heads of the Nile was a fragment of a succulent Euphorbiaceous plant, which, having retained its vitality, was taken by Dr. Thomson to the propagating-pits, and being planted, has now developed into a striking green Euphorbiaceous bush, 7 feet high. It belongs to a very curious genus, Synadenium, closely allied to Euphorbia itself, established by M. Boissier in his excellent monograph of Euphorbia and its allies, published in the fifteenth volume of De Candolle's "Prodromus." *S. Grantii* was found by Captain Grant near villages in lat. 3° 15′ N., in February, 1862, and there only. The Kew plant flowered in November, 1866. It is an erect bush, 6 to 10 feet high, with a stout, terete, green stem, few very thick, erect branches, and columnar branchlets thicker than the thumb. The flowers are crimson, and of very peculiar form.—(*Ibid.*, *t.* 5633.)

Peperomia arifolia *var.* argyreia (Silver-striped Arum-leaved Peperomia).—*Nat. ord.*, Piperaceæ. *Linn.*, Diandria Monogynia. Native of South Brazil. Leaves dark green, with silvery longitudinal bands on the upper surface. Well suited for the front of borders in the house for tropical plants. —(*Ibid.*, *t.* 5634.)

Sophronitis grandiflora, *variety.*—A bright scarlet Orchid, blooming in winter. At Mr. Williams's, Victoria Nursery, Holloway.—(*Floral Mag.*, *pl.* 329.)

Camellia—*Mrs. Dombrain.*—Delicate pink. Introduced by M. Verschaffelt, Ghent, being raised by a Belgian amateur.—(*Ibid.*, *pl.* 330.)

Pompon Chrysanthemums.—*Saint Michael*, bright golden yellow. *The Countess*, pink, softening to white in the centre. *Madge Wildfire*, scarlet, with golden-tipped petals. Raised by Mr. Salter, Versailles Nursery, Hammersmith. — (*Ibid.*, *pl.* 331.)

Zonale Pelargonium—*Miss Martin*—raised by Mr. Groom, Ipswich. Soft rosy peach, truss very large and globular.—(*Ibid.*, *pl.* 332.)

Beurré Clairgeau Pear.—"The Beurré Clairgeau is a Pear which ought to have a place in every garden which is not of the most limited extent. It combines in itself so many of the qualifications that go to make a good fruit, that wherever there is room it ought to find a place. Its size is of the largest, and its colour the brightest, its form is most graceful, and its quality in certain situations is excellent. For the dessert it has few rivals, and as its season extends from the beginning of November till January, it is invaluable for keeping up a supply. The tree is of remarkable fertility, and of moderate size. It does not produce a very vigorous growth, and is consequently well adapted either for bush culture, or for pyramids. To have the fruit in the finest possible condition, it ought to be grown in one of these forms. We have seen dwarf bushes laden with fruit equal in size and colour to that represented in our figure, where proper attention has been paid to thinning and exposure to the sun's rays, and particularly so when it was so near the soil as to benefit from the radiation. On espaliers, or against an east or west wall, we have also seen it produced in high condition.

"This beautiful Pear originated at Nantes about the year 1838, in the garden of Pierre Clairgeau, a gardener in Rue de la Bastille of that city. It first fruited in 1848, and that same year he exhibited it on the 22nd of October at the Horticultural Society of Loire-Inférieur. It is believed to have been produced from a cross between the Brown Beurré and Duchesse d'Angoulême. The original tree was purchased by M. De Jonghe, of Brussels, and formed part of his collection at St. Gilles in the suburbs of that city."—(*Florist and Pomologist*, vi., 45.)

GROUND VINERIES.

From no mention being made by Mr. Broome of the inventor of these valuable structures (see page 179), and from all his remarks being confined to the hinged ground vineries of Mr. Wells, I am inclined to think he has not made himself acquainted with some particulars relating to them, and I am sure he will pardon me for supplying some omissions.

Ground vineries were invented by a gentleman in Sussex, well known for his inventive powers and horticultural skill, about ten years since; and the first idea, under the name of the "curate's vinery" was carried out here (Sawbridgeworth), in 1857-8. The ground vineries under the name just given were glass ridges—still in existence—placed over a furrow lined with slates. Across the furrow were placed slight bars, which supported the Vines, so that the bunches of Grapes were suspended in the furrow. They ripened well, but were liable to mould. In 1860-1 the slate flooring was invented here, to which the Vines were pegged down. This is the mode still in use here.

The next improvement was to make these ridges barless by a very simple process, not patented; and these are so light, elegant-looking, and cheap, as to have superseded ground vineries with bars. The difference in expense between these and the recently invented hinged vineries is so great as to be of much consequence to those who employ these structures largely. Two seven-feet lengths of the barless ground vinery, 3 feet wide, with two closed ends, making a 14-feet ground vinery, will cost, painted, and glazed with 21-oz. glass, £1 19*s.*; while a hinged vinery of the same dimensions costs, or did cost, £5 10*s.* For those who require but one or two vineries, and who can afford to pay the extra price, the hinged one is a most agreeable luxury; but when a Vine is well established, so as to require every season an additional seven, or even two seven-feet lengths, a hinged ground vinery becomes very expensive; and when a Vine reaches to 100 feet in length, which one of mine promises to do, it is rather alarming to have to pay nearly £40 for one's hobby, while the same length of a barless vinery would cost under £14. I need scarcely add that home-made barless ground vineries may be constructed very cheaply. I hope to be allowed to correct, in a kind spirit, a few trifling errors in Mr. Broome's paper.

1. They were not at first exclusively employed for Grape-growing. Lettuces* for early spring salads and Strawberries were planted in the first ground vineries employed here after

* Lettuces of the Cabbage kind, such as Tom Thumb, should be planted early in October, and protected as recommended for bedding plants; they come into use in February, when those imported cost from 4*s.* to 6*s.* per dozen, and are very inferior.

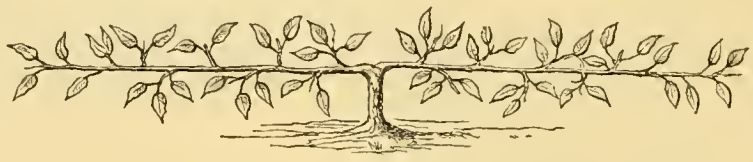
the disuse of the "curate's vinery;" and in 1859 I pointed out the valuable uses they might be employed for, such as "Pears on Quince stocks, Peaches and Nectarines, early Peas, Dwarf Kidney Beans, Cauliflower plants, and many other early vegetables." I mention these trifles only in justice to myself, as Mr. Broome seems not to have been aware of the origin of the ideas he gives.

2. It is bad practice to remove the glass ridge from the Vine in winter; the fruit-spurs often suffer from severe frosts and frozen snow. Here they are never removed except for a short time when the Vines are pruned. If used for bedding plants or other purposes separate structures are necessary—they are cheap enough. All that Mr. Broome says as to the various uses ground vineries can be applied to is correct, although he is rather figurative in saying "a thousand;" still it is on the right side.

3. There is no occasion to give air by lifting the roof or any part of it. The ventilation by bricks placed on the ground lengthwise to support the ground vinery, leaving apertures of 4 or 6 inches (the latter if the garden is warm and confined), between each, was the original idea, and has never been departed from, the success being perfect.

4. The laying down and pegging Peaches, Nectarines, and other trees to perforated slates has not answered well here; red spider, in spite of the slates being strewed with sulphur, constantly injured the trees, and the fruit was not good. A better mode of cultivating fruit trees under these glass ridges is on the double-lateral cordon principle, as in *fig.* 1.

Fig. 1.



The double lateral Cordon Tree.

The two branches may be fastened to a horizontal wire, or supported by slight iron uprights standing 9 inches out of the ground. A ground vinery (*fig.* 2), 3 feet wide at base will hold two rows of these cordons, which are kept in order by summer pinching. Apricots, Peaches, Nectarines, and Pears all do equally well. The Peaches and Pears were in 1866, in spite of the cloudy moist season, remarkably fine. These double lateral cordons should be 21 feet apart in the rows, so that three seven-feet lengths are required for two trees, planted opposite to each other in the central seven-feet length.

5. There is no occasion to admit air at 10 A.M. and shut it off at 2 P.M. From the long experience gained here it is useless trouble, as the ventilation from below is perfect, and no red spider has ever done any injury to the Vines; the evaporation at night is so abundant that the under surfaces of the Vine leaves are drenched with moisture, and red spiders suffocated.

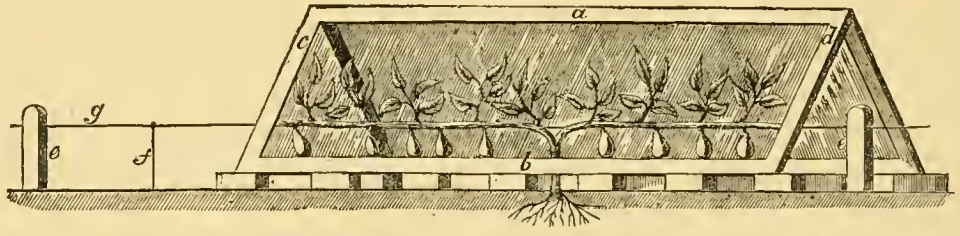
6. The Vines here in ground vineries are never syringed unless dust accumulates on the leaves; they are then thoroughly syringed once just before the fruit begins to colour. The slates are never watered with tepid water; the tepid evaporation at night amply suffices to keep the Vines in health.

Mr. Broome has given some useful hints, for which we owe him thanks; but he seems to have confined himself to one kind of ground vinery, and that the most expensive. He has not given the early history of these most useful structures, and, as it appears to me, has lessened the simplicity of Vine culture in them.

With respect to preserving trees under them from the effects of frost while in blossom, or protecting bedding plants from severe frost, I have elsewhere said that they may be made perfectly frost-proof by layers of straw. To make ground vineries perfectly frost-proof for bedding plants they should be taken from their brick supports as soon as severe frosts commence, and placed on the ground, the two ends closed, so that they are for a time almost hermetically sealed. For two seven-feet lengths, forming a structure 14 feet in length, two or three trusses of straw at a cost of 1*s.* each will keep out the most severe frost known in England. As soon as an interval of mild weather occurs in winter the bricks should be replaced for ventilation, or if the roof is hinged it should be opened. The most convenient size for protecting bedding plants during winter should be of the following dimensions:—Width at base, 42 inches; slope of roof, 28 inches; depth in centre, 20 inches. The cost is of course increased by increase of size, but the large size will be found more economical for bedding plants. Four seven-feet lengths placed so as to form a shelter 28 feet by 3½, closed at each end, will hold a nice little cottage-garden selection. These large glass ridges are also on the whole more economical for Vine culture, as two Vines may be, as they are here, cultivated under one ground vinery, so that there is a saving of something considerable.

In the usual single-vine ground vinery the question is, Which is the better mode of training—pegging down to the slates or training the Vine to a stout iron wire, supported by perforated iron rods about 9 inches from the slate-formed surface, so that the bunches of Grapes are suspended, their tips merely resting on the slates? In 1865 I strictly watched the ripening of my ground-vinery Grapes, and I found that the earliest to ripen were the suspended bunches with their ends resting on the slates.

Fig. 2.



a. The top bar with a groove half an inch deep.
b. The bottom bar with a rebate.
c and *d.* The end bars, each grooved half an inch deep.
e, *e.* Straining-posts 4 inches square, 20 yards asunder, less or more as required.
f. Upright iron rods flattened and perforated at top to pass the wire through.
g. The wire the thickness of whipcord.

With regard to the culture of Strawberries under ground vineries, but few amateurs have yet realised its advantages. The fruit are of the finest possible flavour, they are kept from injury by storms and birds, and all the ills they are liable to. The ground vinery best adapted to Strawberry culture is my favourite the harless kind, 3 feet wide at base. This will hold three rows of Strawberries, which may be 4 inches plant from plant to plant in the rows. To carry out this mode of culture thoroughly a fresh plantation should be made every year in August; and if the plants are taken from pots which have borne a crop in the forcing-house, all the better, otherwise they may be strong runners that have been potted in small pots in June and July. A plantation may be suffered to bear two annual crops; but the second year's crop has been found here to be not so abundant as the first.

In gathering Strawberries from ground vineries, one side of the roof on hinges, so as to be easily opened, is, doubtless, a luxury—the mode of giving air first suggested by the inventor; it would be curious to bring forward one of these original one-side-hinged ground vineries. Whether or no Mr. Wells's patent would be infringed by making one like it, I am not able to say; I should hope not. The method here is, when pruning or gathering Grapes, Strawberries, &c., to have a stout stick, 2 feet long, with a cross piece at top; the ridge is lifted and rests upon this crutch till the work is done. The barless ridges

are very light, and the lifting up one side of a seven-feet length not oppressive; but there is no doubt that one side of the ridge on hinges would be more agreeable. This mode should be followed by Mr. Wells (there is not the least occasion for hingea on both sides), and then he could lower the price of his hinged vineries, so as not to make them objectionable to amateurs with purses not overflowing.

Mr. Broome'e advice as to planting is good, as are, indeed, most of his remarks. The trifling errors I have noticed, I hope kindly, have arisen from his want of experience in the management of ground vineries. To me it seems highly necessary to simplify all new modes of culture, and this feeling alone has tempted me to write this article.

I must not conclude this, I fear, too tedious paper without giving a caution to the planter of Vines in ground vineries. A strong Vine, 6 feet or more in length, and capable of bearing ten or twelve bunches of Grapes, is often left at its full length and suffered to bear profusely the first season. This is ruinous to the Vine, which is often two or three years in recovering its normal vigour. A Vine from 6 to 8 feet long should when planted be cut down to 3 feet, or one of smaller size to 18 inches or 2 feet. Three or four bunches may be allowed the first season, certainly not more. If the Vines are trained to a wire 9 inches from the surface—the most eligible height, they may in time require more head room. This is easily given by adding a brick to each brick originally placed on the ground for ventilation; even a third brick may be added, so as to have a four-inch brick wall of three courses, with apertures for ventilation. In confined town gardens the single row of bricks may not admit air enough: it should, therefore, be known that two or more courses of bricks may remedy the evil.

With regard to the sizes of these vineries for the million—in 1877 they will be in every respectable cottager's garden—there are three:—

No. 1.—Thirty inches wide at base, 15 inches high in centre. This will hold one Vine, pegged down in the centre, and give room enough for many years' growth. My finest Vines are in No. 1 size.

No. 2 is 3 feet wide at base, 18 inches high inside. This size will hold one Vine in the centre, trained to a horizontal wire 9 inches from the surface, or two rows of double cordon Peach, Pear, or Apricot trees.

No. 3 is 3½ feet wide at base, slope of roof 28 inches, height inside 21 inches. This will give room enough for two Vines pegged down to the slates, and requires two ventilating bricks on each side.

I can see no reason why there should not be a No. 4, 4 feet wide; it would make a roomy place for bedding plants, salads, and Strawberries.

If your readers have patience enough to follow me through this article, they will, I think, see that I am what Sterne calls "hobby-horsical" about ground vineries. The truth is, that from the first moment I saw one at the residence of my friend, the inventor, and found him hesitating about making the hinged roof for ventilation, on the score of expense, as he intended them for "the million," and at once adopting my orchard-house idea of low ventilation by placing bricks at intervals to support the ridge, I prognosticated, to use a hackneyed phrase, a great future for these simple garden structures. Ten years' experience has confirmed all my anticipations.—Thos. Rivers.

PLANTING-OUT VERBENA CUTTINGS.

I can fully endorse all that your correspondent stated at page 176, as to the advantages of planting-out spring-struck cuttings of Verbenas. I have adopted the system for some length of time, and have found it answer most admirably; but in one respect I carry it out somewhat differently.

When my cuttings are all well rooted, which they invariably are about the middle or latter part of March, I make up a bed of half-spent dung, put on the frame, and insert a testing stick. In the course of a few days the bed is ready for the plants; I then shake them carefully out of the pots, and have ready a number of square pieces of turf of about 3 inches by 2½ inches. I then scoop a piece out of the centre of each, put in a little sand, and press a little more soil round the roots. The siftings from under the potting-bench answer well for this purpose. I next place the turves as closely together as possible, add a little soil to cover all over, and water. In this way much trouble in watering is saved, and those who adopt the system will be rewarded with strong, stiff, healthy plants. At bedding-out time they may be removed from the bed without receiving any severe check, each having a mass of roots.

Where pots are a consideration, the above plan relieves the gardener from all anxiety on their account, and as to air, I recommend the same treatment as that stated at page 176.—Berkshire.

HARDINESS OF TRITELEIA UNIFLORA.

I write to say that with me Triteleia uniflora is perfectly hardy in the most ordinary garden soil, and without the least protection in winter.

In the autumn of 1865, I purchased half a dozen bulbs and planted them out, understanding them to be quite hardy. These are now a clump, with, at the present moment, seven blooms fully expanded, and ten more in bud. They seem to increase rapidly, and the offsets flower later than the older bulbs, thus prolonging the blooming season. The flowers are as large as a florin, and beautifully tinted with a soft greyish blue; they remain totally unaffected by the changeable weather of the last few days. On the whole, I consider it one of the most exquisite gems of the spring garden. I wonder why it is called "uniflora?" With me each strong bulb sends up two or three footstalks, three of which have this year produced two flowers from one spathe.—A. S. M., *Brentford, Middlesex.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

Another week of winter weather has elapsed, during which rain, sleet, and snow have saturated the ground and prevented the putting in of every crop usually sown or planted in the present month. Even gardens well managed were scarcely ever known to be so little under crop as they are at the present time, or to contain so little either on or in the ground. Scarcely anything is to be seen except mere vestiges of some of the hardier Greens. *Asparagus*, be sure to salt the beds of this and *Sea-kale*; little and often is our maxim. The time is approaching for planting Asparagus; it should not be planted until 6 or 8 inches high. *Cauliflowers* will require to be forwarded by means of hand-lights or other modes of protection, and their growth promoted by stirring the soil and the application of liquid manure. *Carrots*, see to crops of the Early Horn; slugs are very destructive. Nothing, probably, is better than cinder ashes riddled extremely fine and the mere dust taken out; these sown thickly over the ground present such a sharp macadamised kind of surface, that the snails and slugs are at the last point of starvation before they will venture on it. As the cropping has been thrown out of its usual course, it will be necessary to make some additional sowings. *Cabbages*, sow Early Hope or Early Sugarloaf, as such will probably be early in demand; also the Yellow *Savoy* and some *German Greens*. *Kidney Beans* had best be sown in pots in a cool frame for planting out when the ground is sufficiently warm. *Peas* that are being forwarded under glass should be planted out as soon as the weather will permit in rows running east and west, and let them be sticked on the north side only. *Beans*, plant a full succession of the Windsor. *Potatoes*, forward some more early, by sprouting them in a warm place. Sow *Onions*, *Leeks*, *Carrots*, *Parsnips*, *Spinach*, *Turnips*, *Lettuces*, and the Large Red *Tomato* in a little heat.

FRUIT GARDEN.

If the weather prove clear the sun will have great power on fruit trees against south walls. The days being so long blossoms of Apricots and Peaches will expand, and more than usual protection ought to be provided for them, as severe nights frequently occur for some time after so much frost and snow leave the ground. Eradicate insects by all possible means. See that all the winter and early spring work amongst fruit trees is brought to a close forthwith. Finish root-pruning with all luxuriant trees; most persons may have observed the effect of moving a large Pear tree very late in the spring, it generally becomes covered with blossom-buds. Such, in degree, will be the effect of root-pruning at this period.

FLOWER GARDEN.

See that rolling, mowing, &c., proceed in due order. Now is the period to lay the foundation of a fine lawn, the pride of English gardening. Let all fresh turfing be completed forthwith; it is a good plan to scatter rough old tan thinly over it, as a screen from the sun, until the roots take hold; some waterings are also essential. Early herbaceous plants over-

grown may now be divided, the exterior portions of the stools should be reserved and the interior rejected. Be sure in planting again to introduce fresh soil. Cut in all coarse evergreens or shrubs before the buds become too much advanced. This is a good time to clip Holly hedges. Should the weather continue unfavourable very little can be done to florists' flowers; still, if the sun break out warmly in the middle of the day it will be well to protect the frames containing Carnations, Auriculas, &c., at night.

GREENHOUSE AND CONSERVATORY.

The climbers in the conservatory will now want attention, at least once a-week, whether under the roof or on pillars or trellises, in tubs or in pots. Prune off superfluous shoots, stop or pinch the points of gross leaders, to induce a flowering habit in those which produce blossoms from the axils of their leaves, and keep them neatly tied and trained. Large Acacias or gross climbers will require abundance of water; those growing beneath the floor level or under stone covers should, when watered, have a thorough soaking. In the greenhouse keep up a lively circulation of air all the early part of the day, and dispense with fire heat as much as possible. Where a greenhouse of a mixed character has stove as well as common greenhouse plants in it, a climate superior in point of heat to the common greenhouse must be maintained, and in order to do as little mischief as possible through the compromise necessary, let the advances in point of extra heat be made at all times during a considerable degree of light. To this end practice the early shutting-up, so much insisted on by all good gardeners, and on such occasions take care that the fire has been very low or out for an hour or two previously. The heat thus secured for the evening, if accompanied by sufficient atmospheric moisture, will establish a healthy and short-jointed growth. Make a sowing of tender annuals if not already done. Pot off Balsams, Cockscombs, &c. These plants, however, will do better by far in a frame with fermenting materials, close to the glass, and well matted up at night. If the weather continue unfavourable, and the potting-shed is situated so that injury is likely to result from carrying the plants to and fro, erect under the stages, or in some other convenient place, a temporary potting-bench, take in soil, and allow it to acquire the warmth of the house before using it. Look over every plant carefully, and let all that may require it receive attention. After potting keep the house rather close and warm—that is, warmer and closer than usual for a week or so, and at any rate increase the temperature of all plant-structures a few degrees, and slightly shade the newly-potted plants should the sun be bright and warm.

STOVE.

Attend to regular shifting, watering, and a free healthy circulation of air early in the morning, but take care to avoid draughts. Continue to cut down, disroot, and repot those plants which have been flowering through the winter. These will be better removed to a bottom heat of 80° in some spare pit or frame and shaded, treating them as young Pines until they break, when they may, if necessary, be returned to the stove for a time. Follow up the shifting and top-dressing of Orchids in general; syringe freely those on blocks and in baskets. Let this be done early on lively and sunny mornings, giving additional air, with a little fire heat, on such occasions to correct any excess of moisture. Growing Orchids should now be shaded for two or three hours in bright days, more especially those which have been disturbed at the root. These would be far better removed to a house or pit by themselves, as the established plants which have remained undisturbed will enjoy more sunshine.

PITS AND FRAMES.

This being the season for the importation of Tuberoses, they should be procured at once and potted in a mixture of sandy loam, and a small portion of either very rotten sheep or cow dung. They should then be placed in a hotbed or forcing-house. They do not require any water for many days after potting, and but little until they begin to grow, when manure water should be occasionally used. As the plants advance in growth they may be removed to a warm conservatory for blooming, or planted out in a clump after being hardened off a little if the season is warm. Look over the pits and frames, and attend strictly to watering any plants that are dry. If any plants require a shift before bedding-out time it should be now given to them. Continue potting off from cutting-pots, &c. Attend to shifting Lobelias as they advance in growth. Bouvardias should be shaken out and repotted in light sandy soil, and placed in a growing heat of about 65°. Continue making cuttings constantly of Verbenas, Fuchsias, Petunias, Dahlias, Pelargoniums; and shade carefully newly-potted Stocks, and, more especially, cuttings. Remember, in making cuttings, that the leaf should not be first allowed to flag, and then an attempt be made to restore it by abundance of water; the leaf must never be allowed to droop.—W. Keane.

DOINGS OF THE LAST WEEK.

A second winter, and that too when many buds of fruit trees were in a forward state, and, when wet from rain, snow, and sleet, in not the best condition for resisting such a severe frost as visited us on Saturday morning. Some of the days were too wet and slushy to do anything out of doors. When moderately warm a lot of Pelargoniums were potted, and a number of Scarlet Pelargoniums were shaken out of the pots in which they had stood thickly all the winter, and placed singly in turf pots, made by cutting the turf with a sharp knife into pieces about 3½ inches square, and between 2½ and 3 inches deep, a piece being taken out of the centre. Into these the roots were placed along with rich light soil, and the plants were then set under some old lights on the vinery border, as alluded to last week, after repairing these lights in the shed. The end of last week, however, was too cold for such work, and therefore when dry and, as on Saturday, with a bright sun melting the frozen ground in places where it could have access, opportunity was taken to point Pea-stakes out of doors, make up hotbeds, &c.; and indoors, when the weather was unfavourable, washed pots, cut shreds, made tallies, repaired boxes, and prepared flower-stakes, after cleaning snow from the paths, gutters of houses, &c. We will just allude to pots and sticks in passing.

Cleaning Pots.—Independently of appearances, all plants do best when the pots in which they are grown are clean. No rubbing of pots will ever be a substitute for washing them. If a dirty pot or a wet one is employed in potting, it is almost impossible for the ball afterwards to turn out clean. When pots are very dirty and covered with green slime, a little soda may be used with propriety in the water; but, except in such extreme cases, we prefer clean hot water, frequently renewed, and no assistance beyond a brush or coarse cloth and plenty of muscular power. We like the water pretty warm at this season for three reasons: it is much more comfortable for the washers, the work is better and more quickly done than with cold water, and the hotter the water the sooner will the pots be thoroughly dried. Old pots, however frequently used, when thus well cleaned, are quite as good as new ones from the kiln, in one sense better, as the latter for particular purposes require to be soaked and then dried before being used. In general cases the pots are thoroughly washed inside and outside; but in many cases of small pots that will be filled and emptied often in a few months, and more especially if the pots are to be set or plunged in a bed, we direct our attention chiefly to the inside of the pot. We would wish all amateurs who might chance to forget all this, to have it written up at their potting-bench, "Never use a pot twice without washing." We know the injunction is too much neglected, and bad pots are often blamed when the fault ought to be ascribed to want of cleanliness.

Making Tallies is one of those operations with which we would advise amateurs with small gardens to have nothing whatever to do, as tallies of all sizes are advertised at prices at which neither the amateur nor his man could ever hope to make them. In larger gardens, when an odd piece of good splitting deal can be obtained for smaller tallies, and a piece of oak or ash for large out-door ones, the making of them occupies time, when inside work might be scarce in unfavourable weather, and it is well when such matters do not require to be attended to in fine weather. Besides, for many temporary purposes tallies require but little making, little more than cutting them smooth on one side with one or two strokes of the knife. Neat tallies are bought at a much cheaper rate than they can be made in gardens.

Sticks.—The same as a matter of economy may be said of sticks. When they must be bought, those advertised at certain sizes are cheaper than they could be made at home, not only on the principle of the division of labour, but because odd pieces of wood can be made the most of. Why then make or point sticks at home at all? First, because as a matter of taste we like them better, and secondly, because in the case of all small sticks, if collected at home, they cost nothing but the preparation. We have nothing to say against the little sticks

painted green, blue, &c., for those who like them, but we would rather, when a single stick is necessary, have one as inconspicuous as possible. The white sticks made from double laths so commonly in use are to us only endurable when age has made them modestly brown. We, therefore, like better sticks with the varied coloured inconspicuous bark of the Hazel, the Cherry, the Apple, the Pear, and even the slender shoots of the Currant. Prunings in the garden will, therefore, supply at little cost a large number of little sticks from a quarter to half an inch in diameter, and from 12 to 18 inches long. A piece of undergrowth being cut down in a wood; before it was faggoted up we selected many bundles from the size spoken of above, up to those 1 or 2 inches in diameter, and of various lengths, and the bundles of the smallest sizes were prepared in the stormy days. This is much more easily done now than when the shoots had laid longer, as the side spray was easier cut with the knife, and the pointing more easily effected. In pointing such sticks from the smallest size up to those about the thickness of a finger our plan is to make only two cuts with a sharp knife, the first removing half the thickness of the shoot, and the next leaving less than the quarter thickness for the point. These small sticks when thus done, or rather as it is done, are laid in sizes, straightened first if they want it, and then tied in bundles to keep them straight, and if wanted soon are placed over the furnaces to dry all vitality out of them before using them in pots. This drying is necessary in many cases, otherwise the sticks would root in pots, if the latter were in a good heat. Fuchsias grown out of doors on the stool system make neat little sticks, but they must either be well frosted, which leaves the bark ragged, or they must be well dried before using, or every shoot, if in a warm place, will root in the pot where it was only intended for a support. Some years ago we could have had a plantation of young Apple bushes from sticks thus rooted, though they would not have rooted if planted out of doors.

KITCHEN GARDEN.

From what has been stated, little has been done in the open garden, and the severe weather only induced us to put more Sea-kale in the Mushroom-house than we intended, and if a change do not take place soon, we may also be induced to take up a piece more Asparagus. Our last piece under glass is just peeping through the soil, and we did not wish to take up more if we could help it. In some of the worst days we did not uncover Potatoes. Radishes, &c., as there being but little or no heat below them they would not sustain any injury if they had a night of twenty-four or even of forty-eight hours. We could not thus use Cucumbers in dung-beds, though one snowy day we merely uncovered a small portion of the lights, as the heat with long-continued darkness would be apt to draw the plants, and make them tender and impatient of the sun. Even though uncovered almost every day, they had been used to such dull weather that we were obliged to shade a little during the brightest part of the Saturday. It is best to do with little or no shading, but when the changes are sudden from dulness to brightness, a little shading will enable the plants, as it were, time to gather up their energies to meet the force of the sunbeams. A great point will be gained if, when this shading is attended to, it remain not a minute more than is necessary. Do what we will we cannot give to a plant that which it receives from the sunbeam. Shading rightly given often remains on not for minutes but for hours after it is not wanted. Owing to this simple matter cuttings that would strike well in a certain time do not strike in double the time, but become weak and elongated upwards from an excess of shading. This has led us with many common plants at this season, or indeed at any season, not to shade cuttings at all, but to neutralise a bright sun by keeping the cuttings at a greater distance from the glass, and checking evaporation by a slight jet of water from the syringe.

The mention of Cucumbers reminds us of a discussion some time ago, on the comparative merits of hot-water pits or houses, and dung-frames or pits. Our opinion is, that each may be preferable to the other according to circumstances. For winter work we prefer, as giving least trouble, a lean-to house with a steep roof, or a span-roofed house. In either case with plenty of heat at command, the plants would do well from the abundance of light they would receive. In *frames and pits* with a flat roof, the great drawback is the want of direct light in the dull months of the year. At such a time with plenty of manure, a frame is rather better than a fixed flat pit, because you can raise your frame so as to take off the flatness of the glass. For winter work it is always an advantage to be able to go inside and do the necessary work, though there is much truth in what our elder brethren say, that hot water does away with the attention that was requisite to secure Cucumbers in beds and frames heated by dung in winter. After Christmas is past, and the frame or pit is so narrow that all the work has to be done from the outside; then but from the additional attention there is but little to prefer between hot water and dung heat, provided there is plenty of the latter to do all that is wanted. In the latter case there is no expense for fuel, and the manure is useful for the garden when no longer capable of affording heat. Some of the greatest admirers of hot water for everything are beginning to see that they would have been wiser to have kept some of their hotbeds, and thus have secured a supply of manure for the garden, instead of all the manure going to the park and the farm.

Banked-up our frames with litter, fastened small spouts in front to prevent the rains dripping from the sashes and passing into the bed, a matter of importance for keeping in the heat, and covered all round with a layer of laurel boughs. One advantage of having a bed or a pit partially sunk is, that the sides are less exposed. The position, however, must be dry.

Peas.—It is only right we should state here in the way of a caution, that in one of the snowy days when the roofs of the orchard-houses were covered with snow, merely as a precautionary measure, we smoked the house well again with bruised laurel leaves. This did no harm to anything, though there were Deutzias, Dielytras, Cauliflower, Lettuces, &c., in the houses, except the Peas, which were planted out lately. They were, no doubt, a little tender. The upper leaf or two hung as if frosted, and if we had not noticed the appearance before there was much frost, we should have blamed the frost for it. The centre of the shoot, or the axis of growth, is all right, the lower leaves are scarcely if at all affected, and we believe in a few days there will be little sign of anything wrong, but we mention this that those who have Peas in a house may be careful in this respect. We mentioned the other week, that they will not stand even when in an advanced state to be syringed with liquids, which can be thrown against Peach trees in the same house with impunity. In a house, at any rate, our experience leads to the conclusion that no liquid except clean water should go over their foliage.

FRUIT DEPARTMENT.

Strawberries.—Some weeks ago we mentioned seeing little of the green fly on Strawberry plants for years, but it has appeared on the plants in the Peach-house just when in bloom, and not one is to be seen on the Peach trees. On a snowy day the Peach-house was smoked with a little tobacco, and bruised Laurel leaves above it, twice or thrice during the day, leaving the fumigating-pots only half an hour at a time. We never think of smoking during the day, unless in such exceptional circumstances. The fly was pretty well destroyed, and nothing else in the least injured, not even some young Peas in the house; but, then, the smoking was not so strong, and only for a short period at a time. We have had young Peas injured by tobacco smoke and burned tobacco paper when the plants in the house were young before transplanting. The prussic acid in the cool smoke had just been enough for them in the orchard-house, and had we thought it would have affected a single leaf we would have let the smoking alone, or covered the Peas with something until the smoke had gone.

As hinted at last week, the snow threatening to be severe, we shook some litter over the Apricot trees and Peach trees, the former one mass of fruit-buds, and fastened some Laurel boughs over the litter, which will remain on until the weather changes. Some Pears on bush pyramids had their blossom-buds very forward, and we tried some Laurel boughs round them, but we soon saw the remedy was worse than the evil; for the Laurels formed such a hiding-place, that in a few hours hundreds of buds were lying on the ground, as tomtits and bullfinches could work unseen. The buds, however, looked so much affected in consequence of being alternately soaked and frosted, that in the severe frost of Saturday morning we sprinkled a little litter over the trees before the sun touched them; serving, also, the most forward of the Gooseberries in the same way. With the precautions previously adverted to, and the noise of the gun now and then, we have as yet suffered much less than last year in having the buds of bushes and trees destroyed by birds. Gooseberries, especially, have as yet been little touched, but are getting very forward in places, and a little litter may save the fruit.

ORNAMENTAL DEPARTMENT.

Some of the work here has been already alluded to. In a

fair day plants were moved to the conservatory. In bad weather plants were fresh potted, lots of cuttings inserted, seedling Petunias, Lobelias, &c., pricked out and planted where a comfortable heat could be afforded so as to encourage them. During this cold weather in plant-houses and forcing-houses but little air was given. Even in sunny days, as on Friday and Saturday, the sun was allowed to raise the house from 5° to 8° before any air was given, and then almost solely at the apex of the roof. When sun was expected the fires were allowed to go out, and the heating medium thus becoming cool before the sun heat told powerfully on the house, but little air was wanted to sustain a nice genial temperature. This in a Peach-house, where the average temperature at night lately has been from 50° to 55°, and the day temperature in dull weather seldom above 60°, we preferred in such a bright day as Saturday, with a little air early given, that the house should rise gradually to 75° or 80° rather than have it lower by admitting more cold air, freezing hard all day, where the sun did not reach. With the pipes rather cool, a few degrees more merely of sun heat with a little air, to prevent any accumulation of hot vapour, would be better for the plants than a lower temperature from the introduction of more cold air. The Peach-house was almost the only place where more than the exclusion of frost was aimed at. That had front air on Saturday, and only a little, not so much for the Peaches as for the Strawberries in bloom; very small openings ensure a circulation. Many plants suffer in such days from fire heat and sun heat acting together.—R. F.

COVENT GARDEN MARKET.—March 20.

The present inclement weather interferes much both with supply and demand, and interrupts our continental traffic. We have still a large quantity of inferior sorts of Apples sent in, however, and a few good dessert Pears may be had. Potato trade a little better.

TRADE CATALOGUES RECEIVED.

Peter Lawson & Son, George IV. Bridge, Edinburgh, and 28, King Street, Cheapside, London, E.C.—*Catalogue of Agricultural Seeds.*

John Salter, Versailles Nursery, Hammersmith, London, W.—*Descriptive Catalogue of Chrysanthemums, Pyrethrums, Hardy Variegated Plants, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*A Subscriber*).—You can have the Dictionary free by post from our office, if you enclose sixty-eight postage stamps with your address. (*Vicarius*).—Such a work as you require will be published about the close of this year. There is none such at present. If you enclose twenty postage stamps with your direction, you can have Keane's "In-door Gardening" free by post. It contains much of the information you need.

Seaweeds (*Ellen*).—No book answers your wishes so entirely as "Common Seaweeds," by L. L. Clarke, published by Warne & Co, London. It describes them in plain language, has some coloured portraits of Seaweeds, is accurate, and the price only 1*s*.

Old Tan for Ferns (*E. M.*).—You may safely mix it with the soil for Ferns in your rockery under glass. No 1, Onychium japonicum; No 2, a Selaginella, but specimen imperfect.

Glass Edging Tiles (*Cardiff*).—They are manufactured by Messrs. Kilner Brothers, Bottle Merchants, Thames Street, London.

Chinese Sugar Grass (*A. T.*).—It is totally worthless in England for any other purpose than as a green fodder for cattle. As to making sugar or wine from it, as you say Mr. Hullett states you can, it is a statement like those made by the same person relative to ripening Mangosteens, a Passiflora producing fruit of 14 lbs. weight, &c. The Sugar Grass has been tried even in the south of France and failed. The seed may be bought at 1*s*. 6*d*. per lb. of many wholesale seedsmen.

Rutherford's Day and Night Thermometers (*F. E. G.*).—Any mathematical instrument maker can supply them.

Iris Kæmpferi (*G. S.*)—We have never seen it in flower, nor do we know any one who has. There is a coloured drawing of it in "L'Illustration Horticole" for 1858. There is much that is pleasant in what you call "twaddle."

Clematis Around Trees (*Sunny*).—This plant does not injure trees so much as Ivy, but it does to some extent diminish their vigour. It certainly will not smother forest trees.

Pruning Roses (*Idem*).—Early in March is a good time to prune Roses, and if not now done pruning should be completed forthwith. From the middle of February to the middle of March, during mild weather, we consider the best time for pruning Roses. Mignonette sown in the circles will not injure them to any great extent, the trees being well watered in dry weather.

Passion-Flower for Open Air (*Idem*).—There is but one Passion-Flower that will do in our climate, and then it must have a wall with a southern aspect, and protection in winter. It is Passiflora cærules.

Irish Yews Open (*Idem*).—You may tie the branches more closely together, and in that way secure a more compact appearance. You must not prune them, beyond removing irregular growths. Try tying and removing the shoots, but do not draw them too closely together.

Camellias in Bed of Conservatory (*Subscriber, B.*).—The border is not, perhaps, properly made. We would have the plants taken up now, remove all the soil, and at the bottom of the bed place 9 inches of rough stones or brickbats, and then 3 inches of smaller stones or gravel. There should be an outlet for superfluous water at the bottom of the bed beneath the drainage. You may make the drainage any depth, only allow 18 inches above it for soil for the Camellias. If the bed be narrow and the plants trained to a trellis, the bed may be from 2 feet to 2 feet 6 inches deep. We would place a layer of sods, grass side downwards, over the gravel or drainage, and fill the bed with turves cut from a pasture where the soil is a good hazel or yellow loam, and if rather sandy all the better. The turf should be from 1 to 1½ inch thick, and chopped with a spade roughly for the bottom, and rather finely for the top. Raise the bed rather high, tread it firm, then plant the Camellias, covering the surface with an inch of fine soil. Give a good watering after planting, maintain a moist atmosphere, and give frequent syringings overhead. We think your plants will then thrive.

Grapes Shanking (*A Cottage Gardener Reader*).—We should attribute the shanking to the lowness and consequent wetness of the border, coupled with its being badly drained. We are led to this conclusion from the wood ripening so badly. The aspect also is not good.

Shrubland Pet and Prince of Orange Pelargoniums for Bedding (*Inquirer*).—These may be used where Tom Thumb will grow, but they are not effective bedding plants. The Alternantheras lately recommended for bedding purposes, will, so far as we have had experience of them, do fairly in a cold climate during the summer months.

Vines with Terminal Shoots Killed (*W. C. D.*).—As your Vines are ripening their wood we would recommend you to encourage this process as much as you can, and about the time they naturally commence vegetation out of doors you can cut them down, and during the summer you will obtain a growth of wood which may produce a few bunches in 1868. We do not know how the stock of bedding plants is in the country, but you could not do better than advertise.

Snow Plough.—"*G. Bond*" will be obliged by a drawing and a description of a good snow plough. He has one but it requires to be loaded with stones and there must be a team of horse to drag it.

Making Peat Charcoal.—"*T. M.*" asks information respecting making peat charcoal. The peat should be dry, enclosed in an iron vessel with a tube for the escape of moisture, from which pyroligneous acid may be made when peat is charred on a large scale, the iron vessel made air-tight, and placed in an oven with fire round it. I had large works near the Solway in my charge for making peat charcoal for manuring purposes, and about one hundred acres of peat ground for that purpose.—H. O.

Cotton-growing (*J. W. L.*).—We inserted the best possible answer to your inquiry—namely, Major Trevor Clarke's directions for its cultivation. See page 127, of present Volume.

Old Vines Breaking Wearly (*Live and Learn*).—1, With the vigorous state of the old Vines, lime rubbish and a little well-aired loam would have been your best dressing. 2, The Vines being exposed to the open air so long, the roots would most likely have a tendency to go down. 3, The wood formed in such circumstances will require more ripening in the autumn, than wood on Vines with the roots nearer the surface. 4, The fact of the Vines bearing well-coloured fruit last season, is a proof, so far, that there is nothing very much wrong with the Vines. 5, We attribute the failure, the Vines breaking so weakly, and showing tendril-like fruit, chiefly to your hurry in commencing to force in February, and feeling impatient that they did not break freely in a month. You had better have given them six or seven weeks, more especially if, so far as we can make out, the bulk of the roots are in the outside sodden border. 6, As three-parts of the plump-looking buds have not yet broken, and as there is no chance of those which have broken doing any good, we would pull or tear off all the shoots that have come—do not cut or use a knife—lower the temperature of the house to from 50° to 55°, and increase it gradually to 60° in the course of a fortnight, keeping the atmosphere moist, and if your wood was well ripened last autumn (which we rather doubt), you will obtain a crop. 7, The covering of furze on the border, if you had nothing better, we would have let alone.

Sulphur in Coals (*Bob*).—If your watch did really stop from the sulphur fumes coming from a furnace when cleaning it out, it is the first case that has come to our knowledge. That the outside of your watch if silver should become black and tawny in colour we should not have been at all surprised. When we used to have sulphury coals to deal with, we have had the shillings and half-crowns which we carried in our pockets, refused at the shops, and once or twice were threatened with the consequences of attempting to pass bad money. In one place we used very sulphury coals for most of the houses without doing them much injury, but in a stove where a high temperature was required, coals free from sulphur had to be brought from a distance, for if the sulphurous coals were used there would be yellow marks all over the glass in the morning. The houses were all heated by flues, and though no smoke escaped the sulphur fumes would do so when the flues were more than usually hot. There can be no question that all such sulphur fumes are dangerous to animal life. We have frequently had to run out of a stoke-hole, to save ourselves from suffocation, when removing clinkers and cleaning out. We knew of no remedy except tying a cravat or handkerchief over mouth and nose when performing the operation, pulling it down as we went from furnace to furnace, and putting it over both nose and mouth before opening the doors of a fresh furnace. We have not a doubt, that simply by neglecting such a precaution, and carelessly going without preparation from a very hot to a very cold atmosphere many gardeners, humanly speaking, have shortened their days.

Flower-garden Planting (*D. W.*).—With the exception of the Hollies in the centre of the large bed, and Roses for the first ring, followed by Perilla, Calceolaria, &c., we like your planting. The centre of your large bed will be tame in autumn, when all the rest are at their best. The position of your chain beds will greatly modify their planting The cross system is adopted, as No. 1 and No. 13 to pair, but if the two chains are one on each side of an open space, we would prefer 1 and 12 to correspond, 2, 3—16, 17, &c., but this is a matter of taste. We think the planting will look very well.

Vinery (*W. B. H.*).—Provided you mean to take in the space of 16 feet in width, then from the top of your 7 feet 9 inches wall you could have a hipped-roof of 6 feet resting on a ridge about 12 feet from the floor, and which ridge would be about 5 feet from the back wall. If your front wall of brick and glass were 6 feet high, you would thus have a sloping roof of about 12 feet. If your house were narrower and designed chiefly for plants, the simplest mode would be to have your south front, of glas chiefly, the same height as the back wall, and then a span roof. Those who advertise in our columns would give estimates, but the expense will depend on the finishing, and whether the sashes of the roof are moveable or fixed.

Completion of a Greenhouse (*A Subscriber*).—We should not consider that your greenhouse was finished in either the best or a workmanlike manner, if the panes of glass were merely placed on the rebates of the sash-bars, and a tack put in above them on each side, without putty either for bedding or above them. There are modes of dispensing with putty, such as Beard's and others, having the squares to go in a well-fitting groove on each side, or when the glass is fitted in the usual way, but with something softer than wood to rest on, and indian-rubber or some similar material between the tack and the glass. We can hardly say without knowing more of these particulars how the matter would be decided. We would on a common-sense view consider that glazing was understood, putty included, in finishing in the best manner. We have little hesitation in saying, that if the tacks fixing the squares press at once on the glass, you run the risk of having the glass broken and falling out from the want of proper finishing.

Hays's Stove (*Economy*).—We think one of the 60s. stoves would exclude frost from a greenhouse 12 feet by 10. It is more economical and less troublesome than a stove consuming either coal or coke.

Langelier's Nursery, Jersey.—We were in error when we stated there is now no such firm in the island of Jersey. The direction is, Mrs. Langelier, Offices of the Agricultural and Horticultural Society of Jersey, 19, Bath Street, St. Helier's, Jersey.

Heating from a Kitchen Boiler (*J. M. O.*).—To convey hot water from the kitchen boiler up-stairs to heat a small greenhouse, we should prefer the flow-pipe going from the top of the boiler, but it will do very well if taken from the side, but the nearer the top the better. Of course, you are aware that the return-pipe should enter the boiler near its bottom.

Liquid Manure of Fowls' Dung (*O. D.*).—At the rate 1 oz. of dry fowls' dung to a gallon of water a very excellent liquid manure is formed for plants in pots. A Vine does not require it. The book you refer to is "Manures." You can have it free by post from our office if you enclose four postage stamps with your address.

Vine Shoots (*T. C.*).—When two shoots proceed from one eye wait until you see which is fruitful, and then remove that which is unfruitful. If both are fruitful remove the weakest.

Aucuba (*B. B.*).—It is a female plant. You will see by Mr. Standish's advertisement in our Journal last week, that you can have male flowers from him by post.

Making a Bowling-green (*J. G.*).—The dimensions must vary according to circumstances but where there is scope of ground sufficient, bowling-greens should not be less than from half an acre to an acre. The most common form is that of a square moderately extended; but some are made oblong, others circular, though, to suit the general plan or figure of the ground, they may be of any other form. The surface of the greens should be perfectly level, "not rising at all in the centre," and as high, at least, as the general level of the adjoining ground, so that it may be always preserved from stagnant moisture The surface should be levelled in the most exact manner, and laid with the finest grass turf that can be procured from a close pasture, common, or down. The extent and proper levels are then set out with stakes placed round the extremities or boundaries, at 15 or 20 feet distance, on which should be marked the determinate levels of the ground, and from which, on the opposite sides, levels in other crossways at the same distance should be made; and then, according to these levels, proceed by line and spade to form the ground to a proper surface, making it up firmly in lines from stake to stake; the panels or spaces between being made up equally firm and regular, so that no part may sink in a hollow afterwards. The whole should then be raked level, and finished off evenly and smooth 2 or 3 inches deep of light sandy soil, or any light dry poor earth may then, if necessary, be laid evenly over the surface, as equal in quantity as possible. Laying with fresh cut turf, is much superior to sowing with Grass seeds. The turves should be cut each a foot wide, a yard long, and about an inch thick, and laid with exactness, closely joining them edge to edge, then beating them well down with large wooden beaters, repeatedly rolling them with a large heavy iron roller. The best season for performing work of this sort is the autumn, or very early in the spring; but the first is to be preferred when it can be conveniently done, as the turf has time to establish itself well before the hot season sets in. —(*Rees's Cycl*).

Pomme Paradis Stock (*A Subscriber*).—You will find the subject fully discussed in our tenth Volume.

Rainfall (*W. Biggs and Others*).—We have received many meteorological returns for which we cannot afford space at present.

Clerodendron Balfourii Culture (*B. P.*).—Pot in a compost of turfy peat, loam, and leaf mould in equal parts, adding one-fourth silver sand. Sift the leaf mould, but merely chop the peat and loam with a spade. The pot should be well drained. Give a shift into a pot a size larger; and when the plant has grown and made six leaves take out the points of the shoots; or if the plant has not been stopped, cut it back to four joints previous to potting, and when the young shoots are an inch long pot the plant. When the pot is full of roots shift into a pot a size larger, or from a seven-inch into a nine-inch pot, and this will be sufficient for the first season. In spring repot into the same size of pot as that in which the plants were wintered, and when it begins to push afresh cut it back to two or three eyes. When the pot is full of roots shift into one 11 or 13 inches in diameter; and do not stop the shoots, as the plant will most likely flower, but tie them out. Afford a plentiful supply of water, but before any is given let its want be apparent, and maintain a moist, moderately well-ventilated atmosphere, and place the plant near the glass in an unshaded part of the house. When the growth is completed keep the plant dry at the root, and let the atmosphere be dry as well, in order that the wood may become well ripened; but the leaves should not be allowed to flag, nor the shoots to shrivel for want of water. It requires the temperature of a stove.

Watering Inside Vine Border (*A Youngster*).—You should give the border a good watering now and every fortnight until the end of July; then water once a month will be sufficient, the last watering being given in September. You will not require liquid manure this season. A little fire heat now when the Vines are breaking until danger from frosts and cold weather is past, and again in autumn to ripen the wood, will be beneficial and necessary.

Cutting Box—Pruning Evergreens (*Box*).—The best time to cut large overgrown Box-edging is the middle of April, and for Box in good order the end of June is preferable. Evergreens of all kinds are best cut in spring a little before they begin to grow, when they may be cut in close with every prospect of securing a good growth. If the shrubs are required to have a close symmetrical head they should be gone over in August, and any irregular growths removed.

Gardenia fragrans not Flowering (*A Young Gardener*).—We presume your plant casts its buds in consequence of not having sufficiency of heat. If you were to plunge the pots in a mild hotbed it would probably flower freely. Pot it after flowering in a compost of turfy sandy peat and loam, adding sand liberally, and place it in a moist growing heat, such as that of a vinery at work, and when the growths are made afford a light airy situation. When growing water liberally, and in winter keep moderately dry in a temperature of from 50° to 55° from fire heat. In February or March afford an increase of temperature, plunging the pot in a hotbed if you have one; if not, keep it well watered and in a moist atmosphere.

Philadelphus mexicanus not Flowering (*Idem*).—Your plants of this we suppose to be in the open ground, and to have a light open situation unshaded by trees, and plenty of room. If so they will bloom when large enough; but you may hasten their flowering by digging out a trench all around at about 1 foot or 1 foot 6 inches from the stems and below the roots, cutting off any of these that may go down immediately under the stem.

Verbenas Flowering in Pots (*Tweedside*).—The best way to flower Verbenas in pots is to place them into their blooming pots in May, and to peg down the shoots as they grow, bringing them to the rim of the pot. You may stop them to make them bushy up to within six or eight weeks of the time at which you wish them to bloom, tying the shoots neatly to supports. Water freely and overhead daily, using the lights only as protection from heavy rains. When the plants show for bloom liquid manure may be given at every alternate watering. A compost of turfy loam and leaf mould in equal parts suits them well. The pots should be well drained.

Tricyrtis hirta (*Idem*).—This is a hardy herbaceous Japanese plant, but is not hardy in exposed bleak places. It has fine open corymbs of starry flowers, of large size, and spotted with purple. It is as yet scarce.

Charcoal Fire in Fernery (*Pteris*).—The carbonic acid would injure the Ferns and would not kill the insects. You do not state the kind of insects.

Garden with North Aspect (*E. Watts*).—We presume by trees you mean shrubs, and of these Box, green and variegated Hollies, Portugal and common Laurels, common and Irish Yew, Aucuba, and any of the commoner shrubs would thrive. Of flowers you must grow such bulbs and plants as Snowdrops, Crocus, Hepaticas, Primroses, and Polyanthus for early bloom, and in summer depend on Sweet Williams, the common sorts of Roses, Pinks, Pansies, and such old-fashioned perennials. If the place is much shaded by high buildings your best plan will be to have shrubs and grass.

Camellias, Azaleas, and Rhododendrons not Flowering (*A Gardener not in fault*).—You will do well to pot the Camellias and Azaleas now if they require it, placing them afterwards in a vinery at work, as you propose, and keeping them there until the growth is made, when a lighter and more airy structure will be more suitable for them. After the growth is made they cannot have too light and airy a situation. The Rhododendrons, greenhouse kinds we presume, ought not to be placed in heat, but have a light situation in a cool house, with plenty of moisture when making their growth, and copious supplies of water at the root.

Preventing Attacks of Insects (*Rebecca Lane*).—The remedy you name, and now going the round of the papers, is in a great measure obnoxious to insects, especially caterpillars. It will not destroy their eggs, and does no more than cause caterpillars to fall from the trees when the solution is syringed over them. Our experience of it is but limited, but so far as we have tried it, it does not meet our expectations. The best vinegar should be used, diluted with nine times its volume of rain water.

Eriostemon Smithii Culture (*Wexford*).—Shift the plant at once into a nine-inch pot, taking away all the old drainage and loose soil, and if the ball be very firm loosen the sides a little. Drain well, using a compost of turfy sandy peat two-thirds, and one-third turfy sandy loam, with one-sixth of silver sand added. Pot with the collar rather high. Afford a light and airy situation in a cool house, from which frost is merely excluded. Tie down the shoots, and stop any irregular growths to secure a compact plant. Water carefully after potting, but copiously, when the roots are working in the fresh soil. In June, if the plant has grown well, shift it into an 11-inch pot, and place it in a cold pit or cool airy house, stopping and tying out the shoots until the end of June or middle of July. Afford plenty of air, and keep the plant near the glass. In winter keep it near the glass and give abundance of air, with protection from frost, being careful not to overwater, and avoiding a damp, close atmosphere.

Elæocarpus reticulatus (*Idem*).—Its treatment is the same as that of Eriostemons, only it is a taller-growing plant, and does not bloom until it has attained a considerable size. We have bloomed it when 5 feet high, and in its third year.

Large Camellias (*D. C.*).—The best vessel that we have tried for large Camellias are tubs made of oak, which last sufficiently long; but if pots large enough can be had nothing is better. The same remarks apply to Orange trees. We have not tried slate tubs, and do not think them desirable.

Salt for Asparagus-beds (*S*).—The quantity of salt you name is excessive to be put on the beds at once. We advise the salt to be applied at twice—that is, when the beds are dressed in spring give them a dressing of 1½ lb. of salt per square yard, or 24 lbs. for your bed, 30 feet by 5 feet, and you may repeat the application at the end of the cutting, or about the middle of June; 1 lb. per yard will be ample. The weeds will easily be kept under.

Sifting Soil for Pelargoniums (*A Subscriber*).—The soil used for potting Pelargoniums should not be sifted but chopped and made somewhat fine with a spade, and in potting the soil should be made somewhat firm. No riddling is required, as the plants grow much better when the soil is used rather rough, and then it is not so apt to become sodden and sour. A little fine soil may be used for surfacing the pots.

Grafting Sycamore (*G. E. Briscoe*).—We have no experience of grafting the Sycamore with the Platanus occidentalis, nor do we perceive what would be gained by doing so, even if it were successful, as neither it nor Platanus orientalis is sufficiently hardy to bear our climate in exposed situations.

Annuals for Late Blooming (*M. C. T.*).—Centranthus macrosiphon, Alyssum maritimum, Erysimum Peroffskianum, *Dianthus chinensis, Gilia achilleæfolia, Hibiscus africanus, Gypsophila elegans, Godetia rosea alba, Double Clarkia integripetela, C. pulcherrima, *Prince's Feather, *Love-lies-Bleeding, White Rocket and Crimson Candytuft, Centaurea cyanus minor, Bartonia aurea, *Calliopsis cardaminifolia, *C. atrosanguinea, *C. Burridgi, Campanula pentagonia, Convolvulus minor, *Saponaria calabrica and its white variety, Eschscholtzia crocea, and E. tenuifolia, Godetia Lindleyana, Obeliscaria pulcherrima, *Œnothera Lamarckiana, *Nasturtium Tom Thumb scarlet, *crimson, *spotted, and *yellow varieties; Virginian Stock, *Tagetes signata pumila, and *Senecio elegans in variety. Those marked with an asterisk (*) should be sown in April, and the others not until the end of May or early in June. Mignonette should not be omitted. We know of no flowers that are to be depended on for blooming from October to December except Chrysanthemums.

Hardy Perennials (*Ignorama*).—We regret having mislaid your letter. We are making inquiry, and will answer your questions fully shortly.

Ferns Losing their Fronds (*Maiden Hair*).—We consider a house moist enough for the growth of Ferns when there are evaporation-troughs and the walls and every available surface are sprinkled with water twice daily. We do not consider syringing overhead essential or necessary, but, on the contrary, it is destructive to the beauty of many kinds, and also to the young fronds. If you were to sprinkle the walls, paths, &c., with water twice daily, and not syringe the plants overhead, but afford enough water at the root, and yet not so much as to saturate the soil, giving also a fair but not an excessive amount of air, and slight shade from bright sun, we have no doubt that the plants would thrive. We fear you keep them in too high a temperature during the winter, at which season they require a period of rest. A temperature of from 50° to 55° is sufficient for the stove kinds, and one of from 45° to 50° for the greenhouse sorts, increasing the temperature in spring, when, after a season of rest of not less than three months, they will start into growth with increased vigour. Remove the pots from the pans of water at once, and place in the coolest and most shady part of the house. If they require potting now is the best time to perform that operation.

Vine Leaves Browned (*C. S.*).—We never saw more healthy Vine leaves—the bronzed and brown stains on the leaves were caused by bright sunshine, the rays concentrated by lenses formed by dew drops, perhaps. The rust on the berries might be caused by sudden transitions of heat. The very small berries indicate that the bunches ought to have been thinned long since. Freer ventilation, with canvas over the opening to prevent violent currents, is probably desirable.

Error.—At page 193, column 2, line 4 from the top, for "sundried" read "sandy."

Plant Case (*In-door Gardener*).—Some plants can be perfectly well grown in small cases. We have one with Ferns and Cyperuses, and the surface of the soil covered with Selaginella denticulata. Small plants of Azalea indica and Hyacinths remain as long in bloom in such a case as they will in a greenhouse. We have had them all the winter in a sitting-room fire-heated.

Names of Plants (*Mr. Gough*).—Your Orchid was so completely crushed that we could not recognise it. Send a flower or two in a box. (*Nellie*).—Adiantum diaphanum; 2, A. cuneatum: 3, insufficient. (*James Brown*.—Nematanthus longipes. *J. E. W.*.—Hardenbergia Comptoniana. (*W. Hullett*).—Edwardsia grandiflora. (*Vaga*).—Cyanotis vittata, commonly called Tradescantia zebrina; Picea pectinata. (*F. E. W.*).—We cannot tell the name of your plant from the leaves.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 19th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

COMBS AND HOCKS OF DARK BRAHMA POOTRAS.

Excellent articles have been written by "Nemo" and others, explaining the writers' ideas as to what Dark Brahmas should be, and, to a certain extent, what they should not be; but the subject is far from exhausted. It is useless, I fear, looking out for a bird perfect in every respect; two points, however, on which Brahma-fanciers are not agreed—combs and hocks, I wish to say a few words about. Take two cocks, perfect in every way, except that one has a faulty comb and the other vulture hocks, both objectionable, but neither disqualifying for exhibition—I would prefer the bird with the vulture hocks, though I would not condemn altogether a comb slightly twisted and not quite evenly serrated. I would, however, insist on its being triple, not too high, and firmly fixed on the head. At the same time I admire a perfect pea-comb as much as, if not more than, any other point in a pure Brahma, and I consider it a point too much neglected by Brahma-breeders. As to vulture hocks, however, there cannot, in my opinion, be a doubt that they are too much cried down. I would infinitely prefer breeding from a cock with such hocks and heavily-feathered legs to breeding from a nearly bare-legged bird, though he had the most faultless comb a Brahma was ever favoured with. Surely heavily-feathered legs are a great beauty, and yet one of the first professional judges in England told me that most judges look with great suspicion on legs heavily

feathered, and not vulture-hocked, as it was easy, he said, to destroy the objectionable feathers. Well; so be it. A Game cock is sent for exhibition undubbed. He is worthless. Dub him, and he is the most perfect bird the world ever saw. Show a Brahma cock with vulture hocks, but otherwise perfect. He is perhaps commended. Remove the faulty feathers, and, without a dissentient voice, he wins the silver cup. In the Game case all is fair and honest. In that of the Brahma the reverse. In the name of common sense, why? The initiated in the mysteries of poultry can tell, but the outer world lies in utter darkness. In any way if we allow heavy, high, shaky, podgy combs to be overlooked, and vulture hocks to be utterly condemned, however splendidly feathered the leg may be, the result will be a very inferior-looking race of Brahmas.—Falcon.

PIN IN A FOWL'S BREAST.

A few weeks ago I purchased a pen of Black Spanish fowls, and a day or two afterwards a neighbour, who has had much experience in breeding poultry, called in to see my newly-acquired stock. "Well," he said, "the hens are very good, but as for the cock," and then my friend shrugged his shoulders, and performed sundry other pantomimic movements, which were eloquently condemnatory of the bird. "Yes," said I appealingly, "but he has not recovered from the moult yet, the gentleman to whom he belonged assured me that he was a splendid bird, and that he would soon be all right." To this my friend quickly replied, "He will never be right again, look at his comb (it was pale and shrivelled), there is something amiss with him depend upon it." I could only point to the size of the bird, for he was very large, to his plump condition (his appetite was enormous), his fine plumage; but my friend was inexorable, and would look only at his comb. "Well," I said at last, "What shall I do with him?" "Boil him," was the quick rejoinder. Determined, however, to give the cock a fair chance to recover, I tried what careful nursing, and good living would do; but toast and ale, and all the other good things which poultry doctors prescribe, were of no avail; as the tombstones have it, "Physicians was in vain."

So the cock was killed, and in due time boiled. During the operation of dissection which followed, the carving knife grated against something which was evidently neither flesh nor bone, and on examination we found a large pin, coated with rust, embedded in the middle of the breast, and partly fixed in the bone. Here was the explanation of the pale and shrivelled comb. I have reason to believe that the poor bird had carried the pin in its breast for more than twelve months, but how it came there, whether it had entered the gullet and forced its way through the crop, or whether it had pierced through the external skin, I am quite unable to say.—Wm. Stonewall, *Whitby*.

THE USURPING BRAHMA.

"For usurped greatness vengeance is in store;
Short is the date of all ill-gotten power."—(*Lansdowne*.)

Fully do I coincide with "Old Dorking Cock," and your authority quoted in last week's Journal. The fowl for the farmyard ought to be a superior meat-producing bird, a superior egg-producer, and a good forager. Now, the Brahma Pootra is equal but not superior to many other varieties for supplying the egg-basket, but it is inferior almost to all others in the other two requisites. I am quite sure that Game, as well as Dorking fowls, are to be preferred for the farmyard. The flesh of the Game fowl is not so abundant as that of the Dorking, but its flavour is superior. In a quaint poem now before me, a dying Game cock dictates his will, and its very first item is,

"Imprimis—let this never be forgot—
My body I bequeath the kitchen pot,
Decently to be boiled. . . . . ."

I would have proceeded to descant more fully upon the fowl's merits had I not met with the following from the pen of Mr. C. N. Bement, an American authority:—

"If any one should desire the *ne plus ultra* of excellence in a fowl, let him eat and pronounce his opinion on the wing of a well-fed Game pullet, and we will venture to have no fear of his disagreeing with this expression of our judgment on the good qualities of these birds for the table; and Game hens as layers are as good as any, as many as twenty-four eggs being constantly laid by them before manifesting any desire to sit. But with regard to the number of eggs laid by fowls of any breed, previously to their manifesting a desire to incubate, much will depend on whether the eggs are removed and a porcelain egg allowed to remain, or whether to accumulate as day by day the store may receive additional deposits. If the latter plan be adopted, few Game hens, we imagine, would be found to lay beyond what instinct would suggest as the proper complement for their nest, and this we find from twelve to fifteen.

"As sitters, Game hens have no superiors. Quiet on their eggs, regular in the hours of coming off and returning to their charge, and confident from their fearless disposition, of repressing the incursions of any intruders, they rarely fail to bring off good broods. Hatching accomplished, their merits appear in a still more conspicuous light. Ever on their guard, not even a shadow of a bird overhead, or the approach of man or beast, but finds them ready to do battle for their offspring; and instances are on record where rats and other vermin have thus fallen before them. The greatest objection to the Game fowl is its pugnacious propensities."—Coq d'Angleterre.

INQUIRY.

In justice to Mr. M. Brooksbank, 4, Back Rolleston Street, Manchester, I beg to state that he purchased a pair of Spanish hens of me (Rodbard's strain), on the 7th of April, 1866, for which he sent me a post-office order with the order. The letters I received with reference to the same were perfectly straightforward, and in due course I heard from him approving of the hens.

It would be useless my repeating Mr. Wheeler's remarks, but let us "Speak of a man as we find him."—Thomas Ace, *Ystalyfera, near Swansea*.

[We readily insert this second testimonial, for we find that Mr. Brooksbank is quite trustworthy, and we hope that the insertion of the inquiry about Mr. Brooksbank, though it has annoyed him, will be of benefit to him. He has written to us on the subject, and explained that Rolleston Street, Manchester, is not the place where he keeps his poultry. They are at Blackley, four miles from Manchester. We need scarcely add that neither the gentleman who wrote to us nor ourselves had any object in view than the protection of purchasers of poultry, and that we regret that any doubt should have been suggested as to Mr. Brooksbank's respectability. We have had similarly favourable testimonials from Mr. Ellis, of Bracknell, Berks; and Mr. W. May, Lily Hill Farm, Bracknell, Berks.—Eds.]

NEW INCUBATOR.

I crave a few lines of your space to support my principle of scientific incubation by boiling water.

Mr. Brindley admits his incubator varies from 95° to 106°. I guarantee that one on the principle of boiling water shall not vary more than 3° in temperature, even though the external air may range from 30° to 65°. Mr. Brindley admits his incubator to require four minutes daily attention. A steam incubator requires the water supply renewed once a-week, but if the supply-cistern is large enough, it will require no attention at all. In warmer weather I shall have no difficulty, as my pipes go into the hot-air chamber through holes stuffed with padding, and can be withdrawn any distance, thus leaving less piping full of boiling water in the chamber.

Mr. Brindley in saying that the eggs are far removed from the heating source, is in error. In a boiler and pipes properly constructed there is constant circulation, and the temperature of the water in the pipes close to the eggs is the same as that in the boiler—*i. e.*, 212°.

Into the trade question of expense I cannot enter, but will merely say that a tubular boiler can be kept at boiling point by less gas than is required to keep a flat boiler like Mr. Brindley's, at a temperature of 120°.—A. H. S. W.

COMB OF BRAHMA POOTRAS.

I must say a word in reply to those who state that the pea-comb of the Brahma is variable, and I cannot do so better than by stating my own experience as regards this important point in about the best fowl we have ever had.

In 1852-3, I imported as many of the best Brahmas as came to about £150. Of those I parted with enough to return a portion of the outlay, reserving to myself the well-known Uncle Sam and his family of half a dozen hens, a very fine light cock,

with a company of hens, and several nice trios to cross with these, and by that means to avoid in-breeding for many years. Besides unions among these families, I crossed with none but imported birds, except in one instance, and the result has been that in fifteen years I have never had a faulty comb from my own stock.

In the one instance above named, I crossed two years ago, with a good stock in England. Since that I have had now and then, if not quite single, yet faulty combs, but in every case I have been able to trace them to that recent cross, before which I never had such a comb.

Another fact that I have noticed in the Brahmas, is that the pure-bred chickens do not attain an enormous size the first year, but that they are only well-grown healthy chickens the first year, growing and improving up to two or three years old. In many instances Brahmas have been crossed with Dorkings to give dark colour, and this early large growth.

I admire the peculiar pea-comb as much as "NEMO," and feel as anxious as he does to have it left intact. It rests in the hands of breeders. Let all fowls which are the result of the Dorking, or other crosses, for the attainment of size or other supposed advantages, be set aside, and the pure breed adhered to, and I believe variety in comb will no longer be complained of.—E. WATTS.

BREEDING IN SUPERS.

HAVING read "SUDBURY'S" paper in page 98, upon "Breeding in Supers," I shall be much obliged if he will kindly answer the following questions:—I always find drone-comb in supers, although I have used boards with different-sized slits. I should like (if not too much trouble to take for an entire stranger), if he would send me a very small piece of wood just with a *slit* made in it the exact size he uses, then I would show it to the joiner and have an adapting-board or two made?

Last summer I found in one super a large number of drones dead, and the combs all yellow and discoloured. I should be glad to have a cure for this?

Will "SUDBURY" kindly tell me the price of the hives he uses—"Pettitt's Collateral Hives?" I have one of "Nutt's hives," but there is only a round hole in the top, no slits as he describes.

In the case of straw hives, of which I have some, with a round hole in the top of each, what would "SUDBURY" recommend me to do to exclude the queen and drones from any super I might put on?—J. H. WALKER.

YOUNG BEES—SUCCESSFUL DRIVING.

SUNDAY, January 27th, being a fine warm day, I saw a great many young Italian bees come out upon the front board; they came out so numerously that the older bees had not time to dress them, and many in attempting to fly fell to the ground. I picked some off the ground, and examined them closely. I found some very dark coloured, darker than black bees, the old sort, as they are usually called. Perhaps some of the Journal writers will be kind enough to say whether it is unusual for young bees to come out so soon after such severe weather. The hive alluded to stands in a bee-house fronting nearly south, with communication behind at the north, and with little or no protection.

Last autumn I united two hives of driven bees, put them in a common hive about one-third full of empty combs, and fed them with syrup, chiefly made from lump sugar and water, three parts of the former to two of the latter. Thanks to "our Journal" for information respecting bottle-feeding at the top of the hive. I find no way equal to it, as robbers have no chance. I put two more hives of driven black bees into an eight-bar Woodbury hive with three frames full of honey, but no brood. These I did not feed, as I thought they had a sufficient store to last them till spring. I weighed these two stocks of driven bees on November 14th, and weighed the straw hive above alluded to last Saturday, and found it 29 lbs. On November 14th last year it was 30½ lbs., there being only two days short of eleven weeks in the intervening period, yet but 1½ lb. of food consumed. I weighed them again to-day, Monday, January 28th, and they were just 29 lbs. The Woodbury eight-bar hive weighed, November 14th, 28 lbs.; to-day just 26 lbs.—that is, 2 lbs. of food consumed in nearly eleven weeks. Considering the mild weather before Christmas and the season generally, I consider this very trifling.

I should be glad if some experienced bee-keepers would jot down a few notes respecting the wintering of bees, as it may afford information to others as well as to—A. B., *Cheshire*.

[It is not very unusual to find young bees taking wing from strong stocks immediately upon the breaking up of a long frost. Your Italian bees must certainly be hybrids, if any of the young ones are darker than "the old sort."]

BEE GLOVES.

IN my first attempt at bee manipulation with frame hives I put on a pair of kid leather gloves, but very soon found that I could handle the frames much better without them. I therefore pulled off my gloves during my first operation, and have never used them since. I have never experienced so much as one sting on either of my hands, and as to indian-rubber gloves for apiarian purposes, I contend that it is much better to use no gloves. The apiarian can handle the frames much better without them, and if the frames are lifted carefully from the hive there is no danger of being stung. The great secret is to work quietly without any sudden jerk, and I have found that this can be much better done with the bare hands than with gloves of any kind.—SUDBURY.

OUR LETTER BOX.

POULTRY DISORDERED (*H.*).—The cold weather and want of change of food are the probable cause of your fowls moping and dying. Give them soft food once daily, such as barleymeal, bread soaked in ale two or three times a-week, plenty of green food, and under shelter a heap of sand and ashes to husk in.

SPANISH COCK'S COMB BLACK (*Winterlayer*).—It has been frost-bitten. Rub it with camphor ointment, keep the bird in a sheltered run, and feed him liberally.

GROUND OATS (*A. H. D.*).—They are not the same as oatmeal. They are ground, but all the bran left mixed with the flour. They can be obtained from Mr. Agate, Slaugham Mills, near Crawley, Sussex.

LIME FOR FOWLS (*S.*).—Do not mix slaked lime with the food of your fowls, it is corrosive; nor would we mix chalk or any other calcareous matter with their food. Let them have a good supply of bricklayers' rubbish to go to voluntarily.

USEFUL POULTRY (*A Young Hand*).—Brahma Pootra pullets and a coloured Dorking cock would answer your purposes.

PHEASANTS IN AN AVIARY (*Trotters*).—We are strongly in favour of three hens to a cock. We believe four may be put, but we do not agree with those who put five or six. Of course there are more eggs from five than from three hens; but there is not the same proportion of poults to eggs as when a cock has but three hens, or at most four hens with him. One cock and four hens. They will not do well with Partridges.

FRENCH VARIETIES OF POULTRY (*J. R.*).—The La Flèche lay the largest eggs, and we think the greatest number; but they are hard run by the Houdans, which lay very freely. They do not sit. All three are good table fowls, the greatest objection to them being their black legs. The La Flèche is most esteemed in France. Very large experience in all these breeds for some years causes us to place Houdans first, on account of their health and good constitutions. They never ail anything, and they are good in all particulars. We put the La Flèche next; they lay eggs that are unrivalled by any other fowl. While we speak thus we consider them all valuable introductions.

BRAHMA POOTRA EGGS NOT HATCHING (*A. J.*).—The eggs with chickens "glued in" were too dry. They should be wetted every day for a week before the chickens come out. When the hen is off her nest dip your hand in a basin of water and wring your fingers over the eggs till they are wetted. Failing this treatment the inner membrane becomes as tough and dark as indian-rubber, and the poor little chick cannot work his way out.

CANARIES AMONG RHODODENDRONS (*W. S.*).—Leaves of the rhododendron are not poisonous; but at the same time they might possibly have affected the young birds, they being delicate; but we are inclined to fancy that your birds died through being withdrawn from their soft food, and the old birds not allowing them to feed. A dead fir tree is the best to place in a room for breeding, with breeding baskets or boxes hung about it.

PETTITT'S HIVE (*Young Soldier*).—Mr. Pettitt advertises in our columns. If you write to him at Dover he will readily send you all particulars.

FOUL BROOD.—In the second line of the reply to "B. B.," page 203, for *stocks* read "stock."

EMPLOYING EMPTY COMBS—WOODBURY UNICOMB HIVE (*A. B.*).—I should not, if it were my own case, be afraid to use combs which I had collected from apparently healthy sources, although I should, of course, destroy every comb from the infected stock, and having purified the hive to the utmost of my power, should let it lie by for a couple of seasons. My unicomb hive is 23 inches high, by 26½ inches wide inside, and accommodates six combs on bars (not frames). The outer ends of these rest in notches cut in the sides of the hive, the other ends in the centre on projections from a half-inch mahogany upright, the lower end of which is carried by a transverse bar of the same material and diameter. The space between the glass surfaces is an inch and two-thirds, as recommended by Dr. Bevan, whose hive it resembles in its general features. It has, however, the quadruple glass, with air-spaces between each surface, first introduced into observatory hives by Mr. Tegetmeier, and the shutters are not opaque, but are veritable "sun-blinds," or "outside venetians," which admit light freely, whilst they exclude the direct rays of the sun.—A DEVONSHIRE BEE-KEEPER.

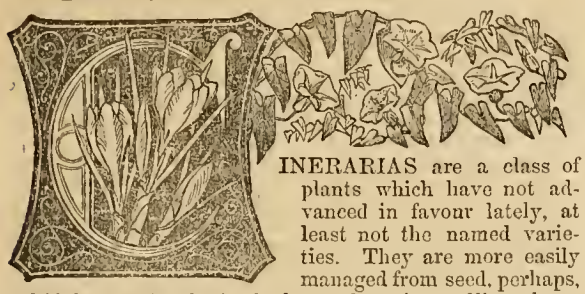
From observations taken near London during the last forty years, the average day temperature of the week is 54.6°; and its night temperature 34.6°. The greatest heat was 78°, on the 3rd, 1848; and the lowest cold 16°, on the 1st, 1838. The greatest fall of rain was 1.19 inch.

THE CULTURE OF THE CINERARIA.



CINERARIAS are a class of plants which have not advanced in favour lately, at least not the named varieties. They are more easily managed from seed, perhaps, and if that can be obtained of a good strain, seedling plants make a good display. For those who are not particular about having all their plants with perfect-shaped flowers, such are the best; but if perfect-shaped flowers are required, and these of certain colours, the named varieties must be cultivated; and what brilliant colours are to be found amongst them! intense blue, deep purple, and glowing crimson. From the length of time, also, during which it continues in flower the Cineraria is one of the most useful of spring-flowering, softwooded, greenhouse plants, and it is certainly deserving of more care than is sometimes bestowed on it, especially when it is considered that the plant may be had in flower from Christmas until May.

Cinerarias are easily cultivated. The best way to propagate the named varieties is by offshoots from the root, and for early bloom this may be done as soon as they can be obtained after the old plants are cut down, and in July and August for late flowering. I pot them singly in 60-sized pots, using a compost of half peat and half turfy loam, chopped fine, liberally mixed with silver sand; part of the compost is sifted in order to obtain some fine mould to place on the surface, using the rougher part at the bottom. Until lately I used leaf mould instead of peat, but I cannot obtain it here so readily as the latter, and I find the offsets do equally well in it. They are then placed in a frame where they have the advantage of a little bottom heat—a Cucumber-frame is as good a place as any—and two rows may be ranged along the front of the frame, which will shade them from the sun. The old plants are kept in a shady corner out of doors, as some of the cuttings may fail, but as soon as a sufficient number of young plants are rooted they are thrown away, and the pots washed and laid aside for future use.

The plants will not all strike root about the same time, but those which show signs of growing are removed to a cold frame until all are ready, and as soon as they are hardened off they are shifted into larger-sized pots, using the same compost, but a less quantity of sand, and adding some rotten cow-manure. The frame in which the plants are now placed has its highest side towards the south, as the Cineraria is very impatient of the direct rays of the sun, and a circulation of air is obtained underneath by the frame being raised on a brick placed at each corner. The plants are kept as near the glass as possible by being elevated on pots; or, which is better, a temporary stage is made with 4½-inch planks cut the length of the frame, inside measure, and placed on pots, using larger pots at the back, so that all the plants may be about 3 inches from the glass when the lights are on and the frame shut. A stage erected in this way has a neat appearance, and the pots may be made to stand level, which is of great importance; for if they do not stand level they cannot be watered properly. The plants must not at any time be allowed to flag, for if they do hosts of insects will make their appearance. They are at all times liable to the attacks of green fly and thrips, both of which ought to be destroyed by fumigating with tobacco, as the leaves are disfigured and permanently injured by being washed with some of the mixtures used for destroying these insects.

If the plants are carefully watered and kept free from insects by fumigating they will grow rapidly, and as soon as they have filled the pots with roots, and before they become pot-bound, they should be shifted into seven-inch pots, using the compost already named, or one of two parts turfy loam, one part leaf mould, some rotten cow-manure, and sand if the loam is not of a sandy nature. The plants intended for early flowering are allowed to flower in these pots, and in general are not pinched back.

The most forward will come in at Christmas, but those which are intended to flower until the Pelargoniums take their place are treated differently; they are pinched back, and shifted into nine-inch pots, and the best place to grow them in is a span-roofed pit running north and south. Here they ought to be arranged as near the glass as possible, and so that the foliage of any two plants may not touch. Care must also be exercised in watering, especially in dull weather; none of the foliage should be wetted, and watering should be performed in the morning, so that the damp may be dried up before the house is closed at night. All mildewed and decayed leaves must be removed as soon as they are observed.

The plants will soon throw up a number of flower-shoots, and to make fine specimens the shoots must be tied out. The best way of doing this is to fasten a wire round the rim of the pot, and draw the shoots towards it with a strip of matting; this must, however, be done carefully, as the stems are very apt to break if bent too much; rather than bend them too much at first it is better to go over them a second time in a week or ten days, and bring them down so that they may ultimately touch the rim of the pot. Enough shoots must be left to fill up the centre of the plant, and these must be trained regularly by stakes thrust in the soil and placed at convenient distances.

After the roots have nearly filled the pots in which the plants are intended to flower (a nine-inch pot is large enough for the finest specimen), they ought to be supplied with liquid manure twice a-week. That which I have found best is made from sheep's-droppings picked up in the field and used fresh, half a bushel being put into a tub along with fifteen gallons of water. After stirring the whole well together, and allowing it to stand for twenty-four hours, the liquid is ready for use; but before applying it an equal quantity of clear water should be added.

Where sheep-droppings are not to be obtained, cow-manure is the next best, but it is not so strong, and a larger proportion may be allowed to the same quantity of water. I have also used guano water; it is more easily managed than the other kinds of liquid manure, as all that is required is to add a pinch to the water before applying it. Guano must be employed with caution, as it varies very much in quality; it is not safe to use more than 1 oz. to a gallon of water, but experience will be the best guide. I remember a case in which some Cinerarias were being grown for exhibition, and all at once they ceased to do well; on sunny days they would droop, and look as if they required water, and the flowers did not open well. Various were the conjectures respecting the cause, and much anxiety was felt, until one of the plants was turned out of the pot, when the greater part of the roots were found to be dead. These plants had been treated in this way: A barrow-load of sheep-droppings was thrown into a tank, a quantity of water added by guess, and the plants watered with the liquid.

The Cinerarias which flower late in the season will have to be shaded as soon as they come into bloom, in order that their beauty may last as long as possible. Any light material will answer for this purpose, the lighter the better; if it break the force of the direct rays of the sun that will be enough, and it ought not to be kept on longer than is necessary; it should not be used to exclude light from the plants. I mention this particularly because I have seen shading put on when the sun's rays were injurious, and kept on night and day to the evident injury of the plants. Dulling the glass with whitening I also think objectionable for the same reason—that it must remain on in shade as well as in sunshine. If the plants are judiciously shaded and watered they will continue in flower a long time, and they certainly have a fine effect arranged in the greenhouse amongst hardwooded plants, as the lively green of the foliage is always pleasing.—J. Douglas, *Loxford Hall.*

FLORIST NOTES AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW.

No greater contrast could possibly be afforded between the scene outside in the garden, and that in the conservatory and arcades, on the day of the first spring show of the season—a cold miserable day, with the snow falling in large flakes, but melting as it fell, and making everything cold, damp, and miserable; within, a display of beauty and fragrance than which I have never seen better at this period of the year, and one could only regret that so few visitors were there to enjoy the rich treat that was provided for them. As the details of the Exhibition have already been given, it will only be needful for me to say a little about some of the more prominent of the florists' flowers, that formed, indeed, the great bulk of the Exhibition.

The Hyacinths were unusually fine, and here, as of late years, Mr. William Paul was pre-eminent. Time was when Mr. Cutbush ran him so closely that it was oftentimes most difficult to decide where the superiority lay, so neck-and-neck was the running. Now we must say the race is won easily in a canter, and it was almost impossible to conceive anything finer than the Hyacinths which gained the chief prizes of the day—prizes, by-the-by, not at all commensurate with the value and beauty of the flowers. Novelties in Hyacinths there were not many, Mr. W. Paul being the only exhibitor; and of his six, two, Sir Henry Havelock and Bird of Paradise, have been exhibited before. Blondin is a flower of peculiar colour and of great substance, a sort of French white, with the back of the petals light blue, throwing a very peculiar shade over the whole flower; large pips, with a well-formed and stout truss—altogether a fine flower. Lord Shaftesbury is a large white flower, very coarse, pips of immense size but few of them, and altogether just one of those sorts of flowers which I should not care to grow. Prince Albert Victor is a fine deep-coloured flower, very showy, deep crimson, the centre of each petal with a deeper band of the same colour; the truss fine and compact—certainly the best flower of the six. Linnæus is a dark crimson erise, a somewhat confused truss. Sir Henry Havelock, exhibited last year, is a flower of peculiar colour, more fitted for giving variety to a stage than for any brilliancy in itself; while Bird of Paradise, also exhibited last year, is a flower of that scarce class single yellow Hyacinths, and is one of a peculiarly delicate shade of primrose. Amongst new flowers in other collections were Vunxbaak and King of the Blues, both of which sustained the high character gained by them when exhibited before.

Is the Cyclamen to become a florists' flower? is a question which might well be asked when looking at the variety and beauty of the collections exhibited by Messrs. E. G. Henderson and Son and Mr. Wiggins, gardener to Mr. Beck, of Isleworth. I was busily engaged examining many fine varieties in the latter collection, when I was joined by a very eminent plantsman, who put a question which will decide this in the negative; for he asked, How can you propagate these bulbs? And there in truth seems the difficulty, or else I do not see why they should not be as fixed in their character as many of those flowers which we already have formed into collections. Mr. Wiggins stated that he had cut out the eyes, and hoped in that way to have increased them, but added that he had failed in doing so. For those, however, who regard this beautiful spring flower for its value as a decorative plant, the collection which he exhibited was one well calculated to give encouragement. I do not speak now of the large and beautifully grown plants which obtained deservedly the first prize, but of the collection of smaller plants. These were all in 48-pots, with from twelve to twenty blooms on each plant, and yet the seed from which these were grown was only sown in March, 1866. They were potted off as soon as large enough, kept growing in a warm house all the year until the leaves were well formed, then placed in a cool frame, and the result was the very beautiful lot of plants which were exhibited. Of these the finest were Oriflamme, a large, fine, high-coloured flower; rubrum grandiflorum, a larger and finer flower than the old rubrum; and giganteum, a fine large white. One of the six which obtained the first prize was purpureum, very dwarf, with remarkably curious foliage, round and somewhat cupped. It was quite the model of what a Cyclamen ought to be. The increased favour with which this beautiful spring flower has come to be regarded, so useful as it is for decoration and also for bouquets, is shown by the far greater number of cultivators, and a knowledge of how very soon a large number of plants may be obtained from seed will probably tend to increase them; for this reason Mr. Wiggins's information may be useful to some of the readers of The Journal of Horticulture.

It is early in the season to talk about Verbenas; yet as far as we can judge, a very valuable addition to their number was shown by Mr. Cruickshanks, gardener to W. Jones Loyd, Esq., Langleybury, near Watford. It is in the style of Striata perfecta and Napoleone Rossi, but apparently better than either of those flowers. The former is, indeed, so very subject to mildew that it has been almost displaced by the latter. If the habit of Lady of Langleybury, as the new flower is called, be equal to its beauty, it will decidedly put the foreign flower aside. This, if it be, as is said, a seedling from Purple King, is likely to be the case; and the profusion of bloom exhibited would rather tend to show that it was very free. A seedling Azalea called Hector was shown by Messrs. F. & A. Smith, of Dulwich, the colour of which was very peculiar—an intense deep crimson; but of this we shall probably see more by-and-by.

Nothing charmed me more than the freshness and beauty of the pot Roses, but as yet nothing new has been exhibited, and only established favourites were brought forward; the sole exception being Princess Mary of Cambridge, of Messrs. Paul and Son, which has greatly improved since it was first exhibited. Nothing could be more brilliantly delicate than some of the blooms on the plants exhibited. It has been the case with it as with the Lord Clyde of the same raisers: coldly looked upon at first, it has gradually risen in estimation, and I believe will take its place amongst the favourite flowers of the rosarian. The delicate rosy pink of its well-shaped flowers contrasted well with the more brilliant colours, and to me it has evidently proved itself an admirable variety for forcing.

Of Camellias I have again to remark that it seems to be an unaccountable fact that a plant so easily managed, so capable of bearing the "fatigues" consequent on an exhibition, and so easy of carriage, should be so sparingly exhibited; and even the cut blooms shown gave but a poor idea of the magnificence and beauty of this queen of flowering shrubs, so universal a favourite as it is; surely this reproach ought to be taken away, and something really worthy of it exhibited.—D., *Deal.*

GARDEN WALK EDGING.

Seeing you have given place to a note on this subject from Aryshire, I send another by an old Aryshire florist, which may be deemed "nae wee sheep shank" in that way.

"Jock Migomery," for that was his name, was known to a good

number of your readers in the west of Scotland; in blooming Auriculas, Tulips, and Ranunculuses, he was not easily beaten, and to have a nice edging for his plots, he hit upon the following device:—

Jock being a pretty good judge of wethers, knew well when to plant himself among the fleshers, to secure a crop of the needful—viz., sheeps' trotters, and by the armful, too, for he was an adept at "felling twa dogs with one bone," first by producing good Scotch Kail with the trotters, and then the sheep shanks served to make the edging in the following manner:—He put the shanks into the earth to the joint, one by one, close to each other, and they produced one of the neatest of edges I have seen, and would afford a good pattern for a potter to copy from for an earthenware edging.—Stewarton.

YORK REGENT POTATOES.

The following is extracted from a communication to the Rev. W. F. Radclyffe:—

"After the disease of Potatoes about twenty years ago, great quantities of Potatoes were sent to London from Yorkshire, of a breed called Scotch Roughs, on account of the roughness of their skins. They created a great noise in London under the new name of York Regents, given them by the cockney dealers, and commanded a great price in the market. Some few gentlemen sent to London for some of them back again, and found them nothing but Scotch Roughs, called also Ruffianers. Hence the name of York Regents. The farmers and country people about here grow scarcely any sort but Scotch Roughs, Ruffianers, or Ruffs, as the same Potatoes are called. Thousands of acres are grown, and these are bought up by men who come round among the farmers, and are called 'Potato Badgers.' They send them all to London under the name of York Regents. All round Potatoes sent to London are named by the dealers 'York Regents,' because they command a better price under that name. Mr. Booth, of Killerby, obtained a new Potato out of Scotland last spring; they are very large, white, good, and good croppers. He sold twenty acres of them to a London dealer; and they were all sold as York Regents! York Regents have a rough skin at one end like scales. If your York Regents are smooth like a Dalmahoy, they are not the right sort. I could find you twenty sorts of the so-called York Regents; some white, some yellow, some good, some bad."

Mr. Radclyffe then adds—"I commenced planting here (Okeford Fitzpaine) February 13th, under grass clots, having previously washed the 'cuts' with vitriol and water. The vitriol discovers a bad Potato within half an hour of its application, by causing discoloration. It may, moreover, remove any fungus about the set. I at present fancy that the disease arises from imperfection of the cellular tissue. Potatoes require rain at the end of May, and none afterwards. Heavy rains in July, when the temperature begins to fall, I think produce the calamity by filling the Potato with more sap than the leaves can elaborate; and hence as an effect the leaves decay."

CUCUMBER FAILURES.

I have had to cultivate winter Cucumbers for some years and in various ways, and I am confident that deep borders and over-watering are the great mistakes in winter Cucumber-growing.

Last summer I had the pleasure of looking over the splendid gardens of Earl Ducie, at Tortworth Court, under the management of Mr. Cramb, the intelligent and skilful gardener. After traversing house after house we came to that devoted to Cucumbers, and I must say it was the most masterly example of Cucumber-growing which I ever witnessed.

The house, a large one to be devoted entirely to Cucumbers, is a lean-to, with a pit running quite to the front. This pit was filled with leaves for bottom heat, but I forgot to ask if there were pipes under the bed or not; and the plants were in pots of rather a large size, which were half plunged in the bed of leaves at equal distances. I was particularly interested in the system of pruning and training adopted; the plants appeared to be allowed to run three parts up the house, and being then stopped developed at every joint shoots which were themselves stopped at a few joints. Although planted twelve months every plant was perfectly clean, healthy, and in no way interfering with its neighbours, and there were several scores of fully developed fruit.

I have adopted the same mode of cultivation—namely, growing Cucumbers in pots plunged to half their depth, and I have succeeded where I always failed before on the border plan.

My conveniences being small, about the middle of September I prepared three 12-inch pots by well draining them, chiefly with the siftings from the potting bench, and filling up the remaining space with good loam and leaf mould. I planted the Cucumbers at once, and the result has been most satisfactory, although the temperature was often down to 55° at night. The plants grew rapidly, and set plenty of fruit, which swelled out to their full size, and I have not had one of those wretched club-headed fruits so common in winter, and which are a sure indication of something being wrong at the roots. One advantage from the pots is that the roots find their way out at the holes in the bottoms of the pots and run among the fermenting leaves, consequently watering is rarely wanted. The plants are not particular about temperature for a few hours if the roots are under favourable conditions and thriving. I would rather find the temperature of my house rather low than strive too much against the weather, but I find a few mats of great service in frosty weather; it will not then be necessary to shade from the first gleam of sunshine that may occur, as is often the case when the plants are in wet borders and weakened by fire heat.—Charles Edwards, *The Gardens, Springfield, near Bristol.*

GARDENER'S DELIGHT PEA—NAITJI ORANGE.

Much appears in "our Journal" about early Peas. Shall I be voted a Goth if I own that I care more about the later sorts? At any rate there is one sort I have not seen named in your pages which I should like, with your permission, to introduce to the notice of all whom it may concern.

I think it was about the year 1859 that my factotum James called my attention to some remarkably fine vigorous stalks of Peas growing amongst a row of Veitch's Perfection—there might be a dozen of them. The pods turned out to be of a corresponding size, literally stuffed with great handsome Peas. I requested that every pod might be carefully saved; this was done, the seed sown in the following year, and a splendid row of Peas I had. They turned out to be very prolific, fine in flavour, and a beautiful colour when dressed. I became curious to know what sort had been thus introduced to me, and consulted all the gardeners I met with just at that time. I happened to have the officials and gardeners connected with our Cottage Gardening Society lunching with me, and of course the new Pea was closely examined and discussed, and greatly admired. There was much good-humoured disputing on the matter, but it soon became evident that no one knew the Pea.

I then sent a small quantity of seed to Mr. J. Smith, now curator, Royal Gardens, Kew, but who at that time had charge of the gardens at Sion House. He told me afterwards, when I had the pleasure of seeing him, that after he had once sent a supply of my Peas to the house there was a constant demand for them, and the cook leaving soon afterwards to take the management of a club, entreated Mr. Smith to give him "if it were only half a pint" of seed, that he might be sure to have the sort for his own supply. The succeeding cook became an equally warm admirer of what was then known at Sion as the "Cornish Pea."

On finding from such high authority as Mr. J. Smith, in addition to the eagerness with which the Pea was sought after by various friends, that it was not merely a fancy of my own, and of James, but that it was superior to the ordinary sorts, I took small packet to Mr. Pince, of Exeter, in the spring of 1863, and requested he would be so good as to grow it for his private table, and let me know what he thought of it. In July I received the following letter from him, the postscript being in his own handwriting:—"We are very much obliged for the Peas sent us some time since under the name of "Gardener's Delight," which we sowed and are daily gathering, and have no hesitation in saying that it is the finest and best-flavoured Pea we have ever seen. We shall esteem it a great favour if you will furnish us with its history, or inform us where the seed is to be procured."—"Mr. Pince presents his respectful compliments and thanks to Miss P. for the delicious Pea of which she kindly sent him some seeds."

I wrote Mr Pince in reply, and sent him two quarts of seed to add to his own supply, on condition that he would introduce the "Gardener's Delight" (the name I had given the Pea from the admiration bestowed upon it), to the public as soon as possible. In October of the same year Mr. Smith called on me,

and I showed him Mr. Pince's testimonial. He said, "I am quite of the same opinion," and told me it was the only Pea produced at Northumberland House on the grand entertainment of the Prince and Princess of Wales. It was the favourite Pea of the Duke and Duchess of Northumberland, as well as of their cooks!

Now I really think I have given you a certificate of merit equal to any that can be produced in behalf of any vegetable grown. I have only to add that I am not in the remotest degree interested in the sale of the seed, but I like to enjoy a flavour "on the palate of my friend," and are not all gardeners and garden lovers friends?—and, especially, are not all who read "our Journal" friends? The seed was sent into the market last year by Mr. Pince, and can still, I believe, be obtained either from him or Messrs. Hurst & Son, Leadenhall Street.

I regret I have none to offer this year, but my last I sent the other day to Mr. Poynter, the very intelligent nurserymen at Taunton.

If you are not weary of this long story I should like to say a word about the mode of sowing Peas.

Can you, or any of your correspondents, tell me anything about the Natjee or Naitji Orange? A friend who had received some plants from the Cape kindly gave me one; he has forgotten from whence it was originally brought into South Africa, and I am desirous to obtain any amount of information possible touching the home and habits of the tree, and the character of its fruit, said to be delicious.—C. P.

MR. WILLIAM PAUL'S SHOW OF SPRING FLOWERS.

This exhibition, held in the eastern conservatory arcade in the Royal Horticultural Society's gardens, South Kensington, opened on Tuesday last, and will continue till the 6th of April. It is in all respects a most admirable display, whether the general arrangement and the choice of the flowers or their individual excellence be considered; in fact, nothing less could be expected from a horticulturist of Mr. Paul's reputation, and who this year, as last, has taken the foremost position as a cultivator of spring flowers. His successes at the recent shows render comment on the merits of the Hyacinths, Tulips, and many of the other subjects composing the exhibition almost superfluous, indeed many of the flowers have been already specially noticed; we shall therefore confine ourselves to giving a short account of the arrangement.

Commencing at the conservatory end of the arcade, the first stage is filled with a large group of Tulips of many varieties in beautiful bloom, with cut blooms of Roses in front. Next, there is in the centre of the arcade a group of remarkably fine pot Roses, conspicuous among which are Alba Rosa and President; then at a short distance there is an oblong table on which are ranged single rows of Chinese Primroses and Crocuses, a double row of Tulips, five rows of Hyacinths, and Narcissuses at the back. The Hyacinths on this stage are arranged in bands of several rows of each colour across the longitudinal rows, and with very good effect. The fourth group is a mixed one of Azaleas, Deutzias, Cytisus, Acacias, Ericastemons, Correas, Cinerarias, Mrs. Pollock Pelargonium, &c.; and the fifth an octagonal stage of Roses, similar to the second group, and containing fine examples of Pierre Notting, Baron Prevost, Maréchal Niel, and other fine varieties in excellent bloom. Next there is a mass of Lilacs, double-flowering Peaches, Clematises, Rhododendrons, Variegated Weigela rosea, Gueldres Rose, &c.; adjoining this a stage filled with a mixed collection of plants in flower; and lastly, a stage on which are ranged about 130 pots of Hyacinths of numerous varieties and with magnificent spikes.

But this is not all; along the front of the arcade, there is a series of tables variously filled. Perhaps the most interesting to many is that at the end farthest from the conservatory on which are placed several of the handsome new varieties of Aucuba, male and female plants in flower, also the handsome Ligustrum japonicum maculatum, variegated Euonymus, &c., with fruiting Aucubas at the back. The second of these tables has small plants of Cytisus Atleeanus as an edging, then a row of variegated Hydrangea, Euonymus radicans variegatus, and at the back E. macrophyllus with beautiful shining green leaves, and the rose and white variegated Vitis Labrusca. On the third table Isolepis and Cytisus, placed alternately, serve as an edging to Cyclamens, Mignonette, pink Hyacinths, and white and blue varieties at the back. The fourth table is filled with Chinese Primulas and Deutzia gracilia, with Dielytra spectabilia at the back; the fifth with purple Crocuses, white and blush Hyacinths, and Narcissuses; the sixth with Isolepis gracilia, Cytisus, mixed Crocuses, Lily of the Valley, and Hyacinths; and the seventh with Hyacinths, Narcissus, &c.

This show, one of the most attractive which have ever been seen at this season, reflects the greatest credit on the skill, enterprise, and resources of Mr. W. Paul, and no one we are confident would willingly miss the gratification which it is calculated to afford.

ROYAL HORTICULTURAL SOCIETY,

March 26th.

At three o'clock Mr. W. Paul delivered a lecture in the Council-room on Spring Flowers, of which his exhibition has been just noticed. Dr. Hegg, F.L.S., in the chair. After a few introductory observations by the Chairman, Mr. Paul proceeded—

The task assigned to me to-day is to give you a popular account of this exhibition. I shall purposely avoid all scientific details; my remarks will be chiefly cultural. Working on the conception that some present would like to hear how these plants are produced, would like to see such in their own gardens, I shall content myself with showing in as concise a manner as possible how that object may be attained.

It is true there is a short road to the possession of these plants—namely, to buy them as at present exhibited. But by purchasing a plant when in the climax of its beauty one does not realise all the pleasure and satisfaction derivable from cultivating it from an early period of growth. It will, I think, be allowed that every stage of progress in a plant is perfect in its way, and there is a freshness, change, and beauty in the gradual development.

I shall commence my observations by bracketing together Hyacinths, Tulips, Narcissi, and Crocuses, which are usually spoken of collectively as Dutch bulbs. Be it observed, these bulbs are among the least costly, most easily cultivated, and most effective of early flowers. Although called Dutch bulbs, originally Hyacinths and Tulips are natives of the Levant, and have been known in this country for nearly three hundred years. Now, however, their descendants, much altered in size, form, and colour, are or should be annually imported from Holland, where their cultivation is carried out on so large a scale as to be an important branch of national industry.

I may perhaps be allowed to remark here that the best Dutch bulbs usually find their way into the hands of the English dealers. The Hyacinths sent to this country are grown from offsets of the root, and are usually four or five years old. In favourable seasons, with free-growing-sorts, or in the event of a scarcity of any particular sort, three-years-old roots are sometimes sent, but such do not produce the finest spikes of flowers. Dutch bulbs usually arrive in England in the month of August, packed in bags and boxes, in what is termed a dry state, in which they somewhat resemble Onions.

Now, with regard to the culture of these bulbs, I will assume that the cultivator has obtained possession of good bulbs, bulbs which have not been hastily forced into the market, but which have the stamp and stamina of age, and which have been skilfully handled throughout their previous stages of development. Without this there is little hope of reaching a high standard of excellence. If you start wrong no after-skill or attention will set you altogether right. Let us then assume the possession of good bulbs. Now, they may be grown in pots or boxes in earth, or in glasses in water. I will first relate how they are managed when grown in earth. Sandy loam enriched by a free addition of manure is the best compost in which to plant them. Plant in October, leaving the apex or crown of the bulb just protruding above the soil, and afterwards thoroughly soak the soil with water. When drained, place the boxes, pots, or vases, in which they are planted on the level soil, covering them over with 6 inches of cocoa fibre, old tan, or cinder ashes. Now, the length of time they should remain under this covering will depend on the period at which they are wanted to bloom. If removed in January, gradually inured to heat and light, well watered if dry, and placed first in a cold frame, and then in a greenhouse with gentle heat, they will bloom in great perfection early in March. If removed in December and a little more heat employed, they will flower early in February. If removed in November they should, a fair amount of heat being employed, flower in January. It should be borne in mind, that a plentiful supply of water is requisite at the period when the leaves and flower-spikes are extending, and during the whole period of flowering. The spikes of flowers should also be tied up almost day by day to preserve their symmetry.

This, then, is the way in which the Hyacinths before you are produced in pots. The rationale of cultivation in glasses in water is the same; but instead of pots, glasses are used; instead of earth, water; instead of covering with fibre we place the glasses, if transparent, in a dark cupboard principally for the reason that the roots feed most freely in the dark. But we must not keep them in the dark too long. Gradually inure them to the light when the roots are fairly developed and before the leaves are 2 inches long. Their season of flowering,

as with Hyacinths in pots, will depend on the temperature of the house or room in which they are grown. It was remarked to me to-day, "Your Hyacinths are unusually short and stout. I have some good spikes, but they are slender, attenuated, and disposed to droop. How is this?" My answer is, They have had at some period of their growth too much heat or too little light; either, or a combination of both influences, would produce the elongation complained of. Tulips, Narcissi, and Crocuses which are of a kindred nature with Hyacinths, should be managed in the same way: all of them may likewise be planted in beds or borders out of doors, a few inches under the soil in the month of November, when the Crocuses will flower in February; the Hyacinths, Tulips, and Narcissi in March and April.

The next plant for consideration is the *Lily of the Valley*. Although a native plant abounding in the woods and hedge-rows in many parts of Britain, it must not be supposed that it could be suddenly drawn thence and produced in the beautiful state in which it is exhibited at our flower shows. There is a major variety, selected doubtless for its size at some former period, and planted in rich soil, where by gross feeding the plant has attained an unusual development. The contents of these pots are prepared for forcing in the following way:—Small pieces or crowns are planted in beds in rich ground, and allowed to remain there for three or four years till the whole bed becomes one mass of roots thickly studded with flowering crowns. They are then cut out with the spade into small patches to suit the size of the pots in which they are grown, placed in the pots in the autumn, when, by subjecting them to different degrees of heat, a succession of flowers may be obtained throughout the winter and spring.

The *Cyclamen* is one of the most beautiful of spring flowers: nothing surpasses it for purity and sweetness. It is a native of Sicily. The plants are raised from seed, which should be sown in June in pots filled with equal parts of sand, loam, and peat. The seed should be quite fresh to ensure germination, and requires to be raised under glass. The plants will not usually flower until the second spring, after which they should continue to increase in size and beauty for many years. When the seedlings lose their leaves, which they should not do till they are about twelve months old, it is important that they be kept in a dry state. Moisture when in a state of rest will certainly injure, and probably destroy them.

We come now to the *Chinese Primula*. This plant is a native of China, whence it was introduced in 1820. It is raised from seeds, which should be sown in the months of May, June, and July successively, in pots filled with light sandy soil, and kept under glass. When the seedlings have made their third or fourth leaf they should be transplanted into small pots, giving each plant a separate pot, and removing it at short intervals into pots of larger sizes. This plant does not dislike heat, but if much heat is employed plenty of air should also be given, or the colours of the flowers will be washy and pale.

There is a curious and interesting fact in the history of plants which the Chinese Primula serves well to illustrate. There is a tendency in most plants to vary in form, size, and colour when transferred from their natural or wild state and subjected to cultivation. The type of the Chinese Primrose of to-day was pink or lilac, and not more than one-fourth of the present size. By culture, through the means of a rich soil and careful attendance, the size was increased, and by watching for even slight variations in form and colour, and selecting such as the parents of future races, the change went gradually on. A break, as it is termed, was at length obtained; that is, a departure from the normal form. A standard of excellence was set up, but it was found that such, although occasionally realised, could not suddenly be retained. Seeds saved from the red Primula would sometimes produce both red and white-flowered plants, and seeds saved from white Primulas would do the same, while the seedlings varied greatly in size, colour, and form. The break was retained, but the result was uncertain. The next step was to fix the alteration. Year after year plants of the altered and more approved form, closely resembling each other, were selected and placed apart, and from these *alone*, seeds were saved until the altered form was fixed again; that is, seed saved from red Primulas produced, with almost unerring certainty, red-flowered varieties; seed saved from white Primulas, white-flowered varieties—both preserving the increased size, altered forms, and clear decided colours of their immediate progenitors. Take another instance:—There are before you plants of the new double crimson Thorn. Strange as it may seem, this is descended from the common Whitethorn or May of our hedges; but this has not happened suddenly, but by a gradation of changes. Most observers will doubtless have noticed in our hedges that some of the plants produce flowers of a pink tinge, though still with single flowers. This is the "break" previously explained: this was step 1. Some of the seedlings raised from these would give flowers of a still deeper colour. This was step 2, which we recognise in the single rose-coloured Thorn, a variety found growing in a hedge at Geddington, in Northamptonshire. Some of the offspring of this would be of a still deeper colour—step 3, the new scarlet Thorn. A seedling or a sport from this or the original May of our hedge-rows would produce double flowers, and here was step 4, the double white or new double pink Thorn. Now I am not asserting that all these steps are authentically recorded, but it is well known to those who are practically engaged in these matters that such is the rule of progress; but the origin of this new double crimson Thorn we do know. It is not a seedling, but what is called a sport from the double pink Thorn—that is, a branch of the double pink produced flowers of this deep and beautiful hue. The branch was budded and grafted, and the young plants so obtained produced flowers of the same vivid colour. In the same way have been produced the many varieties of the common Hawthorn; one of the most notable, the Weeping Thorn, having been selected from a bed of seedlings by General Monkton. The upright-growing variety was also selected from a bed of seedlings by Mr. Renalds, of Brentford. Now, it is the same with leaves as with flowers. Take the Pelargoniums before you. They are all originally produced from green-leaved varieties, either from sports of the branch, or, later in their history, from seeds of the sports so fixed. The first variegated Pelargonium originated by a branch of a green-leaved variety producing variegated leaves. This branch was cultivated till the habit became fixed. The seeds of these were saved and sown, and a brood of young plants was produced retaining the variegation of the parent. The plants before you, which are seedlings, show this tendency; on some there are both green and variegated leaves. Now, to fix either character is the problem. If we wish to retain the green character we nip off all the variegated leaves; if we wish to retain the variegated character we nip off all the green leaves from time to time as they appear, till the plant produces leaves of the one character only. It is the same with the Aucubas before you. The green-leaved variety is the normal form; the variegated kinds are sports either from branches or from seeds. This is, in brief, the process that has been worked out in all cultivated plants where leaves or flowers show a wide divergence from the normal form. I shall conclude my observations to-day with a few remarks on the Camellia.

The *Camellia* is a native of China, a country which has supplied us with many of our richest horticultural treasures. The type of our modern Camellias is a plant with small, single, red flowers, in which the yellow stamens are pleasingly conspicuous. There are now many hundred double sorts, some few of which have been introduced at various times from China, but the majority have been raised from seed in Italy, France, Belgium, England, and America. Most of the double Camellias are grafted on the single red or type, which is found to strike easily from cuttings placed in a cold pit in sandy soil, in the autumn. The grafting is usually performed late in summer, the stocks chosen being two years old. The soil in which Camellias appear to grow best is rough loamy peat with a plentiful admixture of sand. The process of repotting should take place in summer, when the new growth is pretty well matured and the flower-buds about the size of a French Bean. When potting, thorough drainage should be secured. Now, although the plant is nearly hardy, successfully resisting several degrees of frost, it is not well suited for the open air in our climate, on account of the cold and uncertainty of the English spring. Spring is its season of growth, and it then requires a high temperature to induce a vigorous and well-matured growth. At this time, when blooming and growing, a plentiful supply of water should be given, but at all other times, especially in autumn and early winter, water should be given but sparingly. The premature decay and dropping of the flower-buds so often complained of in Camellias, usually arises from too dry a state of the roots at the season of growth, or too wet a state of the roots when the growth is matured, and the plant is in a state of comparative rest. So soon as the growth is matured, it is well to remove the plants from under glass, placing them on the north side of a wall or hedge where they are protected from the midday sun. Camellias may be planted out with advantage in the borders of conservatories, where they will attain the height of 20 or 30 feet, forming umbrageous trees of matchless beauty.

The chief points to look to in their cultivation, then, are these:—

1. To secure thorough drainage in the soil.
2. To give heat and moisture during the periods of flowering and growth.
3. To water sparingly from the time the growth is completed till the flower-buds are about the size of a pea.
4. To secure the leaves from being blistered by the sun, green glass or Hartley's rough plate glass is desirable for the Camellia-house; if ordinary glass be used it should be slightly whitewashed in the month of March.

We have yet to speak of Roses and other forced hardy shrubs; but these will be made the subject of another short paper on Tuesday next.

At the close of the lecture a vote of thanks was given to Mr. Paul for the interesting and instructive information he laid before the Meeting.

On the table of the Council-room were exhibited the prizes offered by the Proprietors of the *Gardeners' Chronicle* and THE JOURNAL OF HORTICULTURE at the Great Bury Show in July next, and which elicited the admiration of all present. The former is an elegant richly chased silver claret jug of beautiful design, and the latter consisted of two very handsome richly gilt ormolu French clocks, with panels and face of painted and jewelled porcelain.

EARLY PEAS.

My experience with Carter's First Crop Pea coincides with that of your correspondent "RONNOC."

Last year I sowed on a south border, side by side, and on

the same day the following sorts—Carter's First Crop, Dickson's First and Best, Dillistone's Early, and Sangster's No. 1. They came in for use on the following dates:—Dickson's First and Best, June 11th; Carter's First Crop, June 16th; the other two sorts about a week afterwards: so that with me Dickson's proved to be five days earlier than Carter's First Crop, and what was of more importance, Dickson's gave double the gatherings that First Crop did, and continued in bearing much longer. I have no hesitation in saying that Dickson's Pea is the very best early Pea I have grown. I discarded all but Dickson's, and Sangster's, for early work this season.

I have no interest in stating the above facts, more than that we may prove which really are the earliest and best vegetables to grow generally. I should like to hear of more gardeners stating their opinions of the above Peas, or any others they think better.—JOHN BROOKES, *Four Oaks Park, Warwickshire.*

ROYAL BOTANIC SOCIETY'S FIRST SPRING SHOW.

THIS was held on Saturday last, chiefly in the conservatory instead of, as usual, in a tent—an innovation which was judged expedient in consequence of the wintry weather experienced up to the previous evening; and although the temperature became milder the change was far from favourable to the success of a flower show, for rain fell more or less till late in the afternoon. In its principal features the Exhibition resembled that held at South Kensington on the previous Tuesday—in fact, a great portion of the subjects shown were reproduced on this occasion, and having been already noticed, will here claim only a passing mention.

Of Hyacinths, Mr. W. Paul's set of twelve were far superior to those from any other exhibitor, and consisted of magnificent examples of Mont Blanc, Van Speyk, Princess Mary of Cambridge, Grandeur à Merveille, Baron Von Tuyll, King of the Blues, Koh-i-Noor, Vuurhaak, Sir Henry Havelock, Solfaterre, Blondin, and Prince Albert. Mr. W. Cutbush, of Barnet, who was second in the Nurserymen's Class, had very good spikes of Von Schiller, Charles Dickens, Cavaignac, General Havelock, Argus, and Ida; and Mr. Kirtland, Albion Nursery, Stoke Newington, was third.

Amateurs' collections of twelve were not up to the mark. Mr. Wheeler, gardener to Sir F. Goldsmid, Bart., Regents' Park, was first; and Mr. Bartlett, Hammersmith, second.

Of new varieties, Mr. W. Paul, who was the only exhibitor, had the first prize for Linnæus, Prince Albert Victor, Lord Shaftesbury, and Blondin, described last week; La Grandesse, with broader and flatter bells than Mont Blanc, and Victor Emmanuel, pale crimson, striped with deeper crimson in the centre of each petal. Mr. W. Paul contributed, in addition, a numerous and very fine collection, in which Carmine, though not remarkable for the size of its spike, was conspicuous by its vivid crimson colour. Lord Cowley, between the silvery grey of Blondin and the pale blue of Princess Mary, was also noticeable.

Tulips were also shown in great beauty by Mr. W. Paul, who was first for eighteen with Vermilion Brilliant; Roi Pepin, white flaked with crimson; Couleur Cardinal, violet-shaded deep red; White Pottebakker; Proserpine, violet-shaded rose; Fabiola, rosy purple and white; Van der Neer, purple shaded with violet; Globe de Rigaut, purple streaked with white; and Keizerskroon. In a numerous collection from the same exhibitor, Brutus rectifié, yellow heavily feathered with crimson scarlet, was very showy. Mr. Kirtland was second, Mr. Cutbush, Barnet, third.

Cyclamens were again shown in great beauty, and Mr. Wiggins and Messrs. E. G. Henderson took the first and second prizes, while Mr. Todman, gardener to R. Hudson, Esq., Clapham Common, was third.

Of Narcissus, an excellent collection was furnished by Mr. Paul, among which Bazelman major, Queen of Yellows, yellow with a deep yellow cup; and Soleil d'Or, yellow with an orange cup, were large and fine. Mr. Paul, Mr. Cutbush, and Mr. Todman likewise furnished fine pots of Lily of the Valley.

Chinese Primulas raised from Mr. Williams's strain of seed, exhibited by Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, were again first, Mr. Todman being second, and Mr. Wheeler third. Prizes were likewise awarded to Mr. Paul and Mr. Todman for cut blooms of Camellias; and Mr. Bull produced plants of the same previously shown at Kensington.

Roses furnished by Mr. W. Paul, in remarkable perfection for the season, constituted an important feature of the display, and it may be useful to notice some of the best. These were Le Rhone with some eighteen blooms and buds, Alba Rosa always very beautiful in spring, President, a splendid specimen with about two dozen blooms; Elizabeth Vigneron, Senateur Vaisse, Cœur de Lion with nine fine blooms; Madame de Stella not fully out, but will be very beautiful; and Madame Victor Verdier. Several stands of cut blooms were furnished by the same exhibitor, and by Messrs. Paul & Son, to both of whom extra prizes were awarded.

For miscellaneous flowering and fine-foliaged plants Mr. Williams, Holloway, was first with Azalea Triumphans in fine bloom, Genetyllis fuchsioides, an excellent specimen of Eriostemon pulchellum, Chamærops humilis, Variegated Aloe-leaved Yucca, and Cordyline indivisa, the last remarkably fine. Mr. Bull, who was second, had a very fine example of Cibotium princeps measuring at least 9 feet across the fronds, Bruhea dulcis, Dracæna australis latifolia, his fine specimen fruiting Aucuba, &c. Mr. Wheeler was third with a collection in which we noticed a good Alocasia metallica, Dicksonia antarctica, Pandanus javanicus variegatus, and a well-bloomed plant of Azalea indica alba. A collection was also furnished by Mr. Paul, consisting of Rhododendrons, Roses, Deutzias, Clematises, Lilacs, flowering Peaches, the fine standard Genista purgans shown at Kensington, and other plants. Mr. Cutbush, Barnet, contributed his fine plants of Mignonette, Acacia Drummondi, and Erica Wilmoreana superba, double-flowering Prunus sinensis, &c.; and Mr. Williams a numerous collection in which were Statice Holfordii, Francisca confertiflora, Anthurium Scherzerianum, Vanda insignis, Genetyllis, variegated Ananassa, Anthurium acaule with five of its long spadices, plaited like a whip-thong, a fine specimen of Agave filifera, Todea pellucida, Lomarias, Gleichenia dicarpa, &c. Of other subjects Mr. Wheeler contributed Chinese Azaleas, and Messrs. Dobson & Son Cinerarias in excellent bloom, the kinds being Duke of Cambridge, large velvety purplish crimson self; John Spencer, paler in colour; Estelle, white, dark disk, and rosy purple edge; Admiration (Dobson), in the same style, but with a broader edge; Favourite, cream white, dark disk, narrow purple edge; and Lady Theodora Grosvenor (Fairbairn), white with deep bluish violet edge. Messrs. Dobson received an extra prize for this collection, and similar prizes were awarded to Mr. Bartlett for Filmy Ferns and miscellaneous flowering plants, to Mr. Ford, gardener to W. E. Hubbard, Esq., St. Leonard's Lodge, Horsham, for Apples and Pears in excellent preservation, and to Mr. Bull and Mr. Williams for collections of new and rare plants, those from the former being nearly the same as exhibited at Kensington.

Among novelties first-class certificates were awarded for the following:—To Mr. Wiggins for a beautiful Cattleya Warscewiczii with a very richly-coloured lip; to Messrs. Jackson, of Kingston, for a variety called delicata, pale pink, with a yellow throat: to Mr. Bull, for Odontoglossum Alexandræ, Cypripedium concolor, and Dayanum; Aralia spathulata and crassifolia picta, Agave macrocantha, Camellia Lavinia Maggi rosea, a beautiful deep rose-coloured variety; variegated Phajus; and Rogeria hybrida, with Laurustinus-like heads of pale rose-coloured blossom. Mr. Williams had similar awards for Amaryllis Ixion, scarlet, with a white band towards the base of the petals; and for Odontoglossum maculosum, the singular flowers of which are green, dotted with brown, and have a hairy white lip. First-class certificates were also awarded to Mr. W. Paul, for his new Hybrid Perpetual Rose Cœur de Lion; and to Mr. Cruickshanks, gardener to W. Jones Loyd, Esq., Langleybury, for his lilac-striped Verbena Lady of Langleybury. Second-class certificates were awarded to Mr. Williams for Ananassa Porteana, differing from the common variegated Pine Apple in having a broad band of yellow down the centre of each leaf, the rest of the leaf being olive green; and Azalea Charmer, a promising rosy-pink variety; to Mr. Bull, for Odontoglossum gloriosum; and to Messrs. E. G. Henderson, for Pyrethrum Golden Feather. The same firm also contributed a collection of tricolor Pelargoniums, as did Mr. Watson, of St. Albans, who had among others, Mrs. Dix and Miss Watson which had previously received certificates.

PROTECTING PEAS AND BEANS.

"R. F.," in "Doings of the Last Week," contributed to your Journal for March 14th, details his method of protecting Beans and Peas from pheasants and partridges, and in a previous Number refers to the "Pea Protector," an illustrated advertisement of which appears in the Journal, and also a description by Mr. J. Douglas, at 199. I beg to state that for several years I have used here, Messrs. Barnard & Bishop's inch mesh galvanised wire netting, 24 inches wide, also advertised in your Journal, for the same purpose, and find it a perfect protection against the smallest birds. It is easily fixed by bending it arch-like over the row, when the Peas begin to break the ground, and pegging it down at the edges with common hooked sticks; in fact, it almost retains its arch-like form without any peg. It may be cut into any length required, and when done with is easily rolled up and stowed away. Its roomy arch also gives ample space for the Peas to grow without clinging to it, until they are quite safe from sparrows, and in such weather as we experience this spring, it affords an excellent skeleton for old matting or litter for protection from frosts and cutting winds. The Pea protector is smaller in its arch, and apparently more expensive, it also seems to be slighter, and I should imagine, therefore, less durable.

My employer has also used the netting above referred to for some years as a guard for young trees, cutting it into lengths of 6, 8, or 10 feet, according to the height of the bole of the tree required to be guarded, and putting it up lengthwise, and lacing it up round the tree with a galvanised wire, and it certainly is much the cheapest and most effective guard used. It perfectly

protects the tree from rabbits, hares, sheep, cattle, and horses. It only requires three or four stakes for the sheep and cattle to rub against, or any fancy guard may be put round the tree on which it is, for unless some such addition be made the sheep will rub the young tree, and wire will cut the bark off very fatally, in consequence of the trunk of the tree swelling and growing until the guard is filled. I have this year unlaced several guards which have been on the trees for years, and they are used for younger trees, and seem as good as ever.

The netting also makes the bottom of young Quickset hedges impervious, if these are planted double about a foot or 18 inches apart, and a piece of netting is strained lengthwise between the rows of Quickset, and fastened up with slight wooden stakes until the quick grows and interlaces the netting, and supports it, which will be the case by the time the stakes have decayed. The hedge may then be clipped over the top of the netting, and the latter be allowed permanently to remain. For short lengths of hedges, and where it is desired to exclude game and poultry, this will be found an admirable plan; of course, a larger mesh may be used, and a narrower width of netting if desired.—William Chastney, *Hamond Lodge, King's Lynn.*

TOWN GARDENING.

(*Concluded from page* 208.)

I must finally state my experience of trees and shrubs, which, however, is not very extensive. Evergreens are generally hopeless, excepting the Box. This cannot be said to flourish; but by putting in plants of a good size at first, and frequently applying the hose to their leaves with a pretty strong flush of water, they may be kept green, and will grow a little. This remark, however, does not apply to Box-edging for borders, which never looks well, and becomes in places very bare.

As regards trees, the great principle to be kept in view is to select those which shed their bark more or less annually, and thus keep continually presenting new portions of healthy surface to the atmosphere. The trees which do this most freely are the Birch and the Plane. The first loses its bark gradually in circular strips; from the second it comes off in blotches. And what more elegant than a drooping Birch, or handsomer in foliage than the Plane? The Weeping Ash splits its bark in long perpendicular seams, sometimes the entire length of the stem, and becomes a very ornamental tree; but care must be taken not to let the branches touch the ground, the grass will not grow under it if they do. This meed of praise does not extend to the common Ash, which ought never to be admitted into a small garden, whether in town or country; for if it succeeds, the roots of one tree only will absorb the moisture of the entire garden: like a young cuckoo in a thrush's nest, it takes full possession, to the destruction of the previous occupants. Nothing will flourish within a radius of 30 or 40 feet of it, as I have often noticed when observing Ash trees in a corn or Turnip field. The Poplar of most kinds splits its bark well, and succeeds in smoke; and even the old stumpy Sycamore when well played upon with water, and treated with an occasional Turkish bath in the form of a scrubbing-brush and soft soap, showed signs of revival, and really began to grow. It was, however, one of a peculiar and delicate species, the name of which I have not discovered. It appeared like a hybrid between a Lime and a Sycamore, in which idea I was confirmed by traces of a cincture on its stem, just below where it diverged into branches, as if it had been grafted; by the few leaves which sprang from its roots having more of the ordinary Sycamore form than those on the branches; and from its occasionally under its new treatment putting forth blossoms, which had a slight fragrance, and of which the bees were fond, but they never produced the keys or seed-vessels. The leaves, however, were soon affected by frost, still more so by a cold or rough wind, and often the tree was nearly stripped of them by the end of June, though a second crop came. On the whole it was not a tree suited for a town garden.

Of flowering trees and shrubs, the Laburnum grows and flowers the best, the Red Hawthorn next. Lilacs require to be well cut-in and watered; they rarely would put forth a flower, but they form a good bushy screen if planted before unsightly objects which it is desirable in a garden to conceal. The Acacia and Almond, though they do well in the squares in the west end of London where there is less smoke, maintained a faint struggle for life only; and my system was to expel everything which conveyed an idea of misery. For the same reason I banished the Ribes, the Gueldres Rose, the Honeysuckle, and the Privet; the last I often pity, with its profusion of black wires, when I see it in the open spaces of the metropolis. I found the wall of the garden facing the east partially covered with Irish Ivy when I succeeded to it. It grew, but it required constant nailing and trouble; for the teeth, or small centipedal lobes, which it puts out at the back of the stems would not retain their hold on the wall. There is, however, a small species with a bright leaf beautifully veined which clings to the wall, but its dying leaves disfigure it, and litter the beds throughout the summer. The Irish Ivy I prevented doing so by having all the old leaves closely sheared off as soon as the new buds began to start in the spring. In two or three weeks' time the wall was again covered with new verdure. On the opposite wall I planted Jasmine, white and yellow. The white flowered annually, more or less, by keeping it well cut-in, but its shoots were always weak. The yellow was a stronger sort and had a larger flower, and the difficulty has been rather to restrain its growth than to promote it. I have seen in some towns the Virginian Creeper do, the scarlet and crimson leaves of which, when decaying, are so rich and beautiful, but it would not grow with me. I apprehend that the climate of England is unfavourable to its perfect development, as I have never observed it in this country put forth its small coral spray, as I have seen it when growing wild in Switzerland. I have also tried the wild English Clematis, called Virgin's Bower, which bore plenty of leaves, but never flowered.

I have now "said my say," and have only to add in conclusion that the garden took up but little of my time, and required little trouble beyond what I could safely trust to a servant or labouring man, as sweeping up, mowing, &c. My time was too fully occupied by engagements of a far more important character to permit of my being much in it. My chief enjoyment on week days during the proper season consisted in snatching those fragments of time which arose when I returned home exhausted from the cultivation of plants of a very different nature (the *Immortelles*), and was five or ten minutes too early for a meal. I then went at once into the garden, and my nervous system was more strengthened and refreshed thereby than by throwing myself into an easy chair, the mind being so completely relieved by the change of objects and ideas. On Sundays it was a still greater treat. Then with my family we had more intervals of leisure; then there was little or no smoke—no overlookers; the busy hum from the neighbouring warehouses was hushed, all was tranquil, and we could sit out with a book at a distance from the south or open end, and when we lifted our eyes and looked beyond saw nothing but sunny hills and cheerful fields; and thus we enjoyed our *rus in urbe* with grateful satisfaction and thankfulness to God.—Philokepos.

MESSRS. CUTBUSH'S SHOW OF SPRING FLOWERS.

This commenced at the Crystal Palace on Saturday last, and will continue open until the 6th of next month. It is, as usual, a very attractive and excellent display, which will doubtless be inspected with interest and pleasure by multitudes of visitors. The plants are admirably arranged, and occupy about 240 feet run of tabling divided down the centre, one side being chiefly filled with Hyacinths and Tulips, the other with a miscellaneous collection of other spring-flowering plants; and at each end is a good flowering specimen of white Azalea indica.

Taking first the side on which are ranged the bulbs we find the first or front row to consist of variegated Pelargoniums, such as Mrs. Pollock, Cloth of Gold, Golden Chain, and Lady Plymouth; the second row of Hyacinths and Tulips mixed; the third row of the same flowers separately and in about equal proportions; and the fourth or back row of Hyacinths only. Among the latter there is a remarkably large and fine spike of Florence Nightingale; and of other varieties of the red class Cavaignac, Macaulay, Von Schiller, Princess Clothilde, Duc de Malakoff, and double Duke of Wellington are excellent. Blues are well represented in Charles Dickens, Grand Lilas, Nimrod, and some others; and the very dark or black kinds in General Havelock and Mimosa. Of the white varieties there are several excellent spikes of Mont Blanc, and some others. Haydn, mauve, is also very pretty. There are a few new kinds, noticeable among which are Le Grand Jaune, buff yellow; Princess Helena, with large, pure white bells; Mrs. James Cutbush, with white bells of good substance; Princess Anna,

a pleasing bright rosy pink variety; and Elise, crimson, edged with pale rose. Of Tulips there is a fine collection, including the Tournesols, Keizerskroon, Vermilion Brilliant, and other showy varieties, besides several new ones, among which the best appear to be Chrysolora, bright yellow; Zilvareen Standard, rosy crimson, flaked with white; Joost Van Vondell, large, crimson and white; Salvator Rosa, double, rose, striped with deeper rose; and Grand Duc, yellow, flaked with red.

The miscellaneous collection of spring-flowering plants principally consists of numerous plants of Dielytra spectabilis, which are very effective. Cytisus racemosus, Deutzias, Acacia Drummondi, Chinese Azaleas, Cinerarias, Mignouette, Gueldres Rose, Lily of the Valley, and the pretty double Prunus sinensis; there are also some Dracænas, and, as an edging to the whole in front, variegated Pelargoniums interspersed with Isolepis gracilis. We also noticed at one end of the table a plate of Messrs. Cutbush's beautifully marked variety of Lilium auratum, called splendidum, in which the central stripes are dull red.

WEEDS ON WALKS, AND HOW TO DESTROY THEM.

Whatever difference of opinion there may exist as to the proper materials for making a walk, every one must agree that weeds destroy its beauty.

Now, as weeds on a walk are unquestionably fatal to its good appearance, their removal or destruction is aimed at by all; but it was not until within the last few years that the application of chemical substances, with the latter object in view, found much favour, and weeding and hoeing were, therefore, the order of the day. A prejudice against the use of one of the most effective destructive agents for a long time kept it from being resorted to, and some people even persisted in the opinion that it would not accomplish the desired end. The old-fashioned mode of employing hand labour was accordingly pursued, and resulted in walks being often allowed to become very rough before the cleaning time came round again.

To remedy this state of things various expedients have been suggested, and different substances tried; some, and by far the greater number, having for their object the destruction of the young weeds on the spot, without disturbing the walk; others being designed to render the walk itself impervious to the roots of weeds, or fatal to them. This, in most cases, is sought to be effected by preparing a walk with a hard, smooth surface of asphalt, concrete, cement, or some similar substance, affording no hold for the roots of the grosser and larger vegetation, but not altogether exempt from the attacks of fungi or mosses, when time has changed the obnoxious substances, and rendered the surface suitable for such vegetation. Asphalt, and similar materials, however useful for walks, are, nevertheless, not yet sufficiently cheap to allow of their being employed everywhere, and weeds are most likely to grow on such walks as are the least likely to be formed of such materials, for it is on walks in out-of-the-way places, that most weeds are produced, not on those over which there is the most traffic.

In districts where mineral substances obnoxious to vegetation can be obtained in sufficient quantity, there is not much difficulty in keeping weeds down, as, for instance, in the case of some mining districts, more especially in the west of England, where a greenish grey sand strongly impregnated with some mineral poison is found in quantity. Certain chemical works also furnish a refuse substance, which can be applied to the same purpose. Such materials, however, are not so generally available as to meet all requirements, consequently we must adopt others more within our reach. I hope that in time something better than any substance we now possess may be discovered—something cheap, easy of application, effectual, and not likely to injure the walks to which it is applied; but till then I fear we must continue to use salt, of which the only fault is, that it makes a damp walk damper still; still its use, I think, is extending, for notwithstanding this drawback, there is nothing as yet to be had at so reasonable a rate, and which is so efficacious. The mere fact of its rendering a damp walk a little damper is not sufficient to cause its condemnation, inasmuch as some walks are better when a little damp than when too dry, and this is the case with many of those here. I have used salt for many years with advantage, and in the past year I employed it more extensively than ever, and I see no reason to regret having done so.

Of the substances used to destroy weeds on walks, one of the best I have seen was a sort of crude arsenic, which was employed about a dozen years ago, and applied, I think, either pounded or in a diluted state. This left no trace behind it, and the walk was clean, and looked as if it would take a long time to return to a state fit for vegetation; but I only saw the effects of the application on one occasion. I have, however, had more than one trial with copperas as a weed-destroyer, but it left a dirty stain, and was so difficult to apply that I cannot recommend it, whereas salt is cleanly, and all trace of it is removed by the first shower. In some places it has been used dissolved in hot water, but the latter is inconvenient to obtain, and I imagine salt acts quite as well without it. Salt, it is true, ought not to remain on a walk when there is company at a place, but by taking advantage of showery weather, it will speedily disappear. Of course, care must be taken in applying it that none be thrown on the edging, otherwise it will kill it; but a little practice will enable any one to do this without danger of such a result. The quantity to apply must depend on circumstances: if the walk is one passing through a meadow where grass seeds abound, and where it is, perhaps, but little used, weeds will grow rapidly, and salt may be more liberally applied; but where there is only a little moss to destroy, a very small dusting will suffice. The best plan for the inexperienced to adopt is to use very little salt at first, to be careful not to scatter any over the roots of Box, if such is grown as an edging, removing the weeds from that part by other means, and if the quantity used do not effect the object, to repeat the application after a time, taking care not to salt too much.

If the keeping down of weeds were the only advantage of using salt, its adoption might be open to many objections; but it likewise keeps worms away, and destroys the weeds without loosening the gravel or other materials composing the walk. This advantage is of the greatest importance where the number of persons who traverse the walks daily is small, for however carefully weeds are picked up by hand, or forced up by the hoe, some disturbance of the surface must be caused, and before that can be fairly remedied, the operation has to be repeated, and a loose, unpleasant surface is the result, or constant rolling becomes necessary. Now with salt nothing is disturbed, the weeds wither and disappear in a few days, and even if they are deep-rooted ones, such as Dandelions and Docks, an extra pinch over the crown will generally kill them.

The substances of which walks may be formed having been treated of in this Journal, I need only remark that where very indifferent materials are necessarily used (which is often enough the case, and yet with such a tolerably good walk may be made), it is of the greatest importance not to disturb this rough material by hunting after weeds; salt is then of the utmost consequence; and where the soil is rich, and wormcasts are troublesome, salt effectually keeps them down. Some examples of this kind we have had here, and the more we use salt the more its benefits appear, for after applying it for two or three years we find a less quantity effect our object, and the advantage of not having the walk disturbed is of consequence on hilly ground, where heavy rains do such injury to walks having a loose surface. I may add that most of our walks have a slight coating of shells, which being broken fine are easy and smooth to walk upon, and after rain the walks are more firm than in dry weather, excepting such as are disturbed by storm-floods, and salting renders it unnecessary to loosen such a light material. Taking, therefore, salt with all its disadvantages, I should be sorry to have to do without it. If, however, any one can discover an agent superior to salt in respect to cheapness, efficacy, and ease of application, I shall be glad to hear of it, and will give it a trial.—J. Robson.

ACCUMULATED HEAT.

I have heard that Mr. Scott Russell has given his opinion that the fire at the Crystal Palace was caused by an explosion of gas in the flue of the hot-water apparatus, which to me appears very improbable. Accidents from the explosion of gas were very common, when the old smoke flue was more generally employed to heat glass houses.

One of the first lessons a young gardener received was, to push back the hot coals well into the flue, and to put the fresh fuel in front of the fire. The fire then burnt gradually towards the door, and all gas given off by the heated fuel was obliged to pass over the fire, and was, of course, consumed. If, on the contrary, the fresh coal was thrown beyond the fire, the gas was wasted, and might cause mischief.

A mixture of coal gas and atmospheric air is explosive. Gas

in a flue *must* be mixed with atmospheric air, and if ignited an explosion, not a fire, will be the consequence. I have seen several of such accidents; the flues were badly cracked, and much smoke and sulphurous acid gas, mixed with vapour of coal tar, were discharged into the house, and all the plants killed or injured; but I never heard of a fire so caused. Under the boiler of a hot-water apparatus the space is generally so short which is provided for fuel, that such an accident is much less likely to occur than in a flue, and I cannot but think the fire in the Crystal Palace is much more likely to be another case of accumulated heat, recently discussed in your columns. —J. R. Pearson, *Chilwell.*

OUT IN THE WEST.

Some of your readers and yourselves may have inquired what has become of me.

Well, to state my tale shortly, I am at Chicago, on the shores of Lake Michigan; and having been here twelve months I think I may tell what may be of use to some of your readers, and give a little information of how we live, and the features and capabilities of the country.

Of the city, in the first place, I may say that if ever there was a wonder in the world Chicago is one, and the rate at which it increases winter and summer is more like that we read of in tales of eastern magic than a sober reality; but here the city is—in solid marble, stone, brick, iron, and wood, the latter predominating. London has few buildings that can surpass the homes of the merchant princes, or their warehouses and stores. About nine thousand buildings of all kinds were erected during 1866, and many at a distance will wonder how a demand could arise for so many buildings, but the wide country that is being settled north, south, and west must be taken into account. The Chicago people have an eye to progress, and have made a network of railways over the boundless prairies on every side of them. These prairies are being settled very rapidly by emigrants from nearly every European nation, and being easily cultivated, the settlers soon become prosperous farmers, and the market for their produce is Chicago, with its lake and railway outlets to almost any part of the American continent and to Europe.

The prairies are almost destitute of trees save on the edges of streams, and for twenty or thirty miles the eye will not see a tree, save such as have been planted by the farmers about their homesteads. The soil is a rich black mould, in many places from 3 to 10 feet deep, formed by ages of decayed vegetation. Those who do not own a yard of land, but can mow well, make good livings when they are within fifteen or twenty miles of the city, for they mow the unoccupied prairie, and make hay, which they sell in the city, and I know several who have made a good start in the world by doing so. Others take to shooting game in the season, and make well out in the autumn and early part of winter. In the lakes and rivers fish abound; any one can catch them, and many make a living by doing so. My son, a boy twelve years old, has caught as many as a hundred good perch per day. I have seen men and boys pull fish weighing 8 or 10 lbs. out of the lake with the throw-line. The country is rich in itself, and any willing handy man who is sober can get on. Chicago is no place for clerks, for women do a good deal of book-keeping here; still, somehow, male clerks are absorbed; but I know one instance of a young Englishman who came here as a clerk, but he had to turn farm labourer. As a gardener a man may expect to have a little rough work, but there are good places to be had.

Chicago is a city of flowers, and they command a good price; Camellias sell for a dollar each, and very small bouquets will in winter bring from two to five dollars. There are numerous English, Dutch, and Germans engaged in the business, with some Frenchmen and Americans, and all seem to make a living. Most of the greenhouses are of wood, except those attached to private dwellings. Vines are beginning to be very much cultivated under glass, and some gentlemen have built very large vineries. One gentleman named Dunham, who is now in Europe, has a large collection of Vines, and his name is worthy of mention for his liberal behaviour towards his chief gardener, an Englishman named Williams, who has been with him eleven years, and for whom he has built a house which cost 1500 dollars, besides paying him a good salary. There are many good places in the State, but there are few at which stove plants are kept. Gardeners must not expect to find all they could wish, but all may live if they will only take things somewhat as they come for a time. I have done a considerable amount of carpenter's work since I came out in fitting up greenhouses and frames, and the foreman carpenter at the school said I would soon make a first-rate carpenter.

I must now say a little about the wild flowers and fruit. Grapes grow wild in the woods skirting the prairies, and are abundant. There are also plenty of wild Plums, which produce larger fruit than I have seen them do in England; but Hazel nuts are smaller, and the bushes scarcely grow more than 4 feet high in the woods along the southern shore of Lake Michigan, which is probably owing to the poor sandy character of the soil. Further down in the State of Illinois I have seen them larger. On the south side of Chicago the formation of the surface is peculiar, and the trees are mostly Oaks, of which I have only seen three species—the Quercus tinctoria, nigra, and rubra. The shrubs found underneath them are Cornus canadensis or Dogwood, with several species of Spiræas. There are some other plants which I have not been able to name yet, but I may give your readers an account of them in a future paper. For about two miles west from the lake the land lies in ridges with, of course, alternate furrows, and these ridges and furrows stretch ten or twelve miles along the lake shore. The ridges are very sandy, and upon them grow the only trees and shrubs to be seen, save those which have been planted by the residents. The furrows are wet land called sloughs or "slews" here, and in them but few woody or shrubby plants grow. Early in spring they are literally covered with Iris versicolor; this is succeeded by an abundance of wild Strawberries which are very fine; my children have often gathered two quarts of the fruit in half an hour. The cultivated Strawberry lives and does well on these "slew" lands; one gardener near us planted twenty acres last spring. Some very pretty orchidaceous plants grow in these places, also a small upright Lobelia not unlike Lobelia erinus. Towards autumn there are some pretty Chelones, and a very pretty plant the flower of which much resembles that of our Foxglove, Sesamum indicum, or Oily Grain as it is called here.

Along the sandy shore of the lake and in the woods early in spring may be seen some thousands of Phlox maculata, and I wonder it has never been cultivated in England, it would be a gem in shrubberies, especially in sandy lands. There is also a pretty Violet (Viola palmata), abundant here, as well as three or four other species. I found Convallaria racemosa plentifully, and the pretty two-leaved Claytonia virginica. Another early summer flower is the Dodecatheon meadia, of which the umbels of pinkish white flowers are very pretty. Batschia canescens and B. longiflora are pretty yellow and orange-coloured flowers, and are plentiful on the lake shore, and in the woods. Lupines are very plentiful in the woods, and so is Osmunda regalis in the swampy parts, and some other Ferns that I have not made out yet, having no good work on American Ferns. I have made a collection of many other plants, of which when I have leisure I hope to give your readers an account.

I will now offer a few remarks on the crops we grow out here. Onions produce fine crops with poor tillage, and in poor sandy land I have seen them 6 or 8 inches in diameter, not here and there odd ones, but the majority of the bulbs of those sizes; out on the prairies they grow wonderfully well, and so do Carrots, Beet, Parsnips, and Asparagus. Cabbages do tolerably well, but are liable to "break their hearts;" Cauliflowers poorly on account of the almost dry heat in summer, and they are bitter. I have seen no Curled Greens. Early and late Peas succeed well, but not summer Peas. Cucumbers of the small sorts, Tomatoes, Pumpkins, Squashes, and various kinds of Vegetable Marrows, along with Musk and Water Melons are "great institutions," and are grown everywhere, and by almost everybody. I grew about seventy bushels of Tomatoes, about forty bushels of Cucumbers, and of Squashes and Pumpkins I do not know how much. Indian Corn is raised in large quantities, especially the sweet varieties for eating in a green state.

Flowers such as Verbenas, Pelargoniums, Phlox Drummondi, Petunias, Balsams, Cockscombs, Globe Amaranths, and Dahlias do remarkably well. Roses are soon spoiled in the summer, but the Perpetuals do well before and after the summer heats are passed. The tender annuals I have named have to be raised under glass as in England, and bedded out in the beginning of June. Ageratums, French Marigolds, and most kinds of annuals do well and make a good show after the heat of summer. German Asters and Stocks should be sown twice or thrice, for they are soon over. Chicago is a great place for bedding out, as nearly every house has a piece of land attached, and bedding plants are raised extensively by the florists.

I will now say a little about the climate. About the beginning of December the severe frosts set in, and last more or

less until March. During this time we have two or three "cold snaps" as they are called here, when the thermometer falls 18° or 20° below zero; then one takes to dancing early in the morning, in fact as soon as he jumps out of bed, and everything he touches in the way of iron is thrown down again as if red hot. Fortunately these cold snaps only last about three days at a time, and the useful and pretty American stoves soon drive out the frost so as to render the temperature bearable. Almost all work is at a standstill whilst the cold snaps continue. It freezes almost every night during the period I have named, but on most days we have plenty of sun—in fact, a fine clear atmosphere, and greenhouse plants do well. There are few out-door evergreens save Arbor Vitæ and Firs. From March to the beginning of May we have occasional frosts, but about the 10th of May corn planting and Cucumber sowing are performed, and the corn will grow in eight or nine weeks as many feet high, so that when vegetation does start fairly no time is lost. About September we begin to have slight frosts again, and then come the autumn tints, which are beyond my power to fairly describe. The leaves of the Oak assume almost all the tints of the rainbow; and where Oaks are intermixed with other trees, such as Poplars and Willows, with their pale yellow leaves, they are a sight not to be forgotten. One range of forest will look like an immense flower garden consisting of miles of Verbenas, Petunias, and Calceolarias; another part will look like miles of "shot silk" and the hues will keep changing according to the hour of the day. This season is called the "Indian summer," and I think it the best part of the year in America, for there are fine, warm, sunny days and cool nights.

I will now make a few remarks as to the expense of getting here and the cost of land, for I know many are anxious to come out; in fact, the Mayor of Windsor some time ago wrote to the Mayor of Chicago for reliable information, in order to make such known among English farmers who have been much affected by the cattle plague. The expense, which is not great, depends on the part of a ship in which a person takes a berth. For a passenger in the first or second cabins it is from £15 to £20, in the steerage from £4 10*s.* to £8 8*s.* The agents in England will book passengers through to any part of America; but to those who contemplate coming over, I would say, Book only across the Atlantic, if they can afford to spend £1 or 30*s.* more to Chicago, for they will save it in expenses if they do not travel by emigrant trains, which are so long on the road, and sometimes stop one or two nights at different depôts, which puts the traveller to extra expense. On this side of the Atlantic passengers can book through by express trains, and will as a rule be more civilly treated than in the emigrant cars, besides having more comfortable cars to ride in. The express trains run here in from twenty-four to forty hours according to the weather, and, the emigrant trains will take from four to six days and nights. If a person can spare about 1½ dollar he can go to bed at night in the express trains, lie there as comfortably as if at home, and awake in the morning a long way on his journey; but the cars are comfortable in the United States, while those for second-class passengers are dreary, uncushioned, and wooden-seated in Canada. I do not know how the third class cars are, but I was very glad that I had but one short night's ride through Western Canada. Emigrants will find clean water in the cars and water-closets; and if they bring a can with a lid on that will hold one or two quarts, they may make tea or coffee for themselves in the cars, which will save money if they carry provisions along with them.

Land is very dear near the cities—that is, from ten to twelve miles from them. Near Chicago land sells at from 200 to 2000 dollars per acre, but out on the prairies it sells at from 7 to 50 dollars per acre. A man with £500 or £600 would be in a good position for life, but many have extensive farms all paid for who came here as labourers. I must now conclude with the advice to all contemplating coming out, Do not expect to find a fortune without hard work and care.—John Hague, *Reform Schools, Chicago, Illinois.*—(*Late of Ashton-under-Lyne.*)

[Heartily welcomed was this communication. Some of our readers will remember that Mr. Hague and ourselves co-operated in exertions to help the Lancashire weavers fond of botany during the Cotton famine.—Eds.]

NOTES AND GLEANINGS.

There is now in bloom at the Denbies, near Dorking, a handsome plant of Rhododendron longifolium, one of the Sikkim species. Mr. Drewett, under whose skilful management it has been induced to flower, says, "The plant is about 6 feet high, and covered with flowering buds, I believe seventy in all. It is certainly one of the most beautiful Rhododendrons I ever saw. I have had the plant, with others of its class, since 1851; so you will perceive it requires a good share of patience to wait for the flower."

—— On Saturday next, the 30th inst., Dr. Masters will deliver the first of a series of lectures on "Plant Architecture" at the rooms of the Royal Horticultural Society, South Kensington, at three o'clock.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The classification of work is at all times of the utmost importance, more especially at this period. There are maxims in gardening established by long practice, which if borne in mind by the amateur or the tyro, would save in no small degree the task of repetition in calenders. For instance; in sowing-operations there are certain vegetables for which, in order to produce a continuous succession, no better rule can be offered than to sow a succession as soon as the preceding sowing is fairly above ground. Such may be said of Peas, Beans, Horn Carrots for drawing young, Radishes, Spinach, small salads, &c. Again, with regard to plants for early-forcing purposes, the forming of buds or shoots by one set introduced into the forcing-pit should be the signal for the introduction of a succession. In matters of propagation, likewise, the cuttings of various flowers for a summer display should be collected, if at all possible, simultaneously, struck in a frame or pit together, and nursed together afterwards. They always meet with more steady and uniform treatment under such a course, and it conduces likewise to the easy dispatch of business. I shall this week say a few words about *Asparagus* planting. It is of the utmost importance in kitchen gardening to give every attention to a proper rotation of crops. It is recommended to grow all the *Celery* in what are called Scotch beds, these beds to be from 5 to 6 feet wide, and every year to break up an old Asparagus-bed or two in order to force it; part of the Celery ground being prepared in a special way with a view to its being laid down in Asparagus. The preparation consists in trenching it much deeper than the rest, and in burying a considerable quantity of fresh vegetable matter in the bottom of the trench, old refuse, vegetables, Cabbage stalks, weeds, or, what is very good, half-rotten leaves, mixed with a little manure used for linings in the previous year. The upper part of the beds has more rotten manure, of course, for the Celery. In taking up the Celery for use, the bed is broken-up to a great depth, and the alleys with it, and thrown into a ridge, which ridge remains as a fallow until planting-time, when it is merely levelled. It may be planted about the middle of April. Dress Asparagus-beds, let the surface be carefully forked over so as not to injure the crowns of the plants. The soil should be finely broken so that no compact portions may remain to obstruct the progress of the shoots. *Artichokes*, dress. *Cardoons*, sow a few. *Peas*, keep up successions of these. Dickson's Favourite, Bishop's New Long-podded, Knight's Dwarf, and Flack's Imperial Victory may now be sown. *Potatoes*, plant. The frost having made a premature clearance of Broccoli and other crops usually succeeded by Potatoes, the latter will derive advantage from an earlier possession of the ground than would have otherwise been the case. Sow *Parsnips*, *Beet*, *Turnips*, *Radishes*, Paris Cos *Lettuce*, *Savoy*, *Nasturtium*, *Sweet Basil*, &c.

FRUIT GARDEN.

Peach and Nectarine trees on walls are now coming into full bloom, and may require slight protection at night, especially when coping-boards have not been put up. Gauze of cotton material may be obtained for little more than 1*d.* a-yard, and if only two breadths of such be placed judiciously along the front of the wall, a sufficient protection will be afforded against such frosts as usually occur after this period. The substance being light is not apt to be torn by the wind as are some thicker fabrics. The grafting of Plums and Cherries should be concluded as soon as possible, and that of Pears and Apples proceeded with. In grafting old trees of the last-mentioned, two or even three-year-old wood may be used if very strong young shoots cannot be obtained.

FLOWER GARDEN.

The planting of shrubs, laying of Box, &c., if not already finished must now be brought to a close as soon as possible

before dry weather sets in. Finish digging if not already done, turn gravel, edge and clean walks, &c. Examine half-hardy plants, such as have been protected through this severe winter, and remove the covering, unless an unfavourable change in the weather takes place. Do not yet prune tender Roses, they might be much injured by so doing until they begin to grow, which will soon be the case if fine weather sets in. Sow Sweet Peas in borders and pots, also hardy annuals. Plant-out from the reserve garden Phloxes, Pentstemons, &c. Auriculas, those beautiful spring flowers, will now require very great attention. They may have occasional warm and genial showers any time previous to the development of the flowers. The pots to be kept free from weeds, giving the plants all the air possible, avoiding rough windy weather. Polyanthuses, look the beds carefully over and any plants loosened by the frosts should be immediately secured. Tulips in spite of the past severe weather are looking well. Keep the wet from lodging in the hearts of the plants; it is apt at this season to be frozen, and the mass of ice has a pernicious effect on the rising bud. Pansy and Pink-beds must be carefully dressed with some decayed vegetable matter, omitting the rich compost till later in the spring.

GREENHOUSE AND CONSERVATORY.

A thorough revision of all the various tribes in the different houses where plant-growing and forcing are carried on in a mixed way is necessary at one period or other during the spring, the shutting-up of late vineries or Peach-houses generally offering facilities for this arrangement, and of course for relieving the other structures. It is of the greatest importance to keep plants classified or in families as much as possible, which, as well as facilitating business, will add a zest to these structures. Exhausted forcing stock should by all means have a pit or frame fitted up especially for it. The plants should by no means be allowed to mix with the general stock. A bed of fermenting material of a mild character, covered 6 or 8 inches deep with tan and well topped up with linings, and matted at night, is required. A bottom heat of 80°, with frequent syringings, and plunging the plants in it, will restore them to perfect heath and prepare them for another campaign. Fuchsias will be benefited by the application of clear liquid manure. Very liberal shifts will be necessary at this period, more especially with those intended for very large specimens. Cinerarias for late blooming should, if pot-bound, be shifted likewise. Let plants in need of water have immediate attention; nothing conduces more to the encouragement of insects than suffering plants to become checked through drought. This is now the proper time to regulate the branches of Pelargoniums intended for early flowering. Let the shoots be brought into their exact position and carefully tied to short stakes. Those intended for late flowering should be potted immediately in their blooming-pots, and kept cool to promote the production of wood rather than flowers at this time.

PITS AND FRAMES.

Follow the directions given in last week's calendar. Look over bedding-out stock, and if you are short of any kinds now is the time to remedy the evil by putting in cuttings or seeds. Some of the more hardy plants might be removed to colder situations to harden, but by no means expose them to the mercy of the weather yet. Brompton and Ten-week Stocks that have been kept in pots in frames through winter might be prepared by exposure to the air for a short time for planting out. Shut up early every fine day to forward the growth of any sickly plants, or such as are most wanted to be increased, and prick off tender annuals as fast as room can be made for them. Water them sparingly until they begin to grow freely for fear of damp, &c. German and Ten-week Stocks may also be sown in fresh soil in a cold frame, or one that will soon cool down, and a few Early German Asters on a slight heat.—W. Keane.

DOINGS OF THE LAST WEEK.

What a change from Saturday, the 16th, to Saturday, the 23rd of March!—a difference in temperature of more than 30°. Then, again, a drifting, dry, frosted snow on the 22nd, and a warm rain dispersing the last relics of the snow on the 23rd. During the week up to that time, with the exception of some rough jobs, all out-door work was reduced to a minimum, as even covering and uncovering pits and frames was let alone, except where there was extra heat, as in the case of Cucumbers. We think it, therefore, a good opportunity to say a few words to meet the wants and wishes of several correspondents on stoves and boilers, and more especially as we have had to alter the arrangements of an iron stove in our orchard-house.

Stoves.—On commencing these gossiping articles, one of the first had reference to an iron stove which we made use of when in the severe frost of 1860 and 1861 our boiler for the conservatory gave way, and we had to depend on an old iron stove that had been discarded from an entrance-hall, for keeping out the frost. There was fixed to the stove, about 6 inches from the top, on one side, a horizontal pipe, about 3½ inches in diameter, and 5½ feet in length, and this was so rivetted to the stove, that we concluded that any attempt to move the pipe would bring the stove itself in its ricketty state to grief. This long pipe, and lengthened by another almost as long, was very well, so long as the stove stood in the entrance-hall with the pipe terminating in a lofty chimney, and thus securing plenty of draught; but it was contrary to all our experience of stoves to have such a long horizontal pipe terminated with a short upright one as a chimney, and therefore we have constantly recommended that for all such stoves the horizontal pipe from the stove, before it takes a perpendicular or upright direction, should not exceed from 12 to 24 inches in length. A correspondent particularly wishes to know "why a little iron stove with the smoke-flue or pipe proceeding at once from the top of the stove should not answer as well as the having the smoke pipe proceeding from the side, as in the section of a stove shown in the 'Heating Manual,' page 18." We do not perceive why such a stove would not answer for general purposes where merely heating a corridor, warehouse, &c., is concerned, or even when a very mild heat was applied in a small plant-house; but we would object to such a stove in a plant-house of any extent, chiefly because the heat would too freely pass up the chimney-pipe, and that would become very hot, whilst the lower part of the stove was comparatively cool; the great merit of all stoves used in plant-houses should be the giving out enough of heat economically, and yet the stove itself never in any part to be so hot as to burn the particles floating in the air in its vicinity. We would prefer, too, that all stoves for such gardening purposes should have a moveable top, as then the inside can be cleaned and examined at pleasure.

We would not wish for a better stove for a large house than that to which we have been referring. It is 2 feet 9 inches in height, and 18 inches square, outside measure, the bottom raised a couple of inches or so from the ground. There are two moveable tops, the inner one a piece of sheet iron, resting in a small groove, and when put on, the groove, and even this inner top, are covered with sand; then the plain outer top is put on, and when at work the top is covered with an iron vessel for evaporating moisture. The fireplace, which stands in the middle of the stove, is made of iron, about 13 inches square, and a foot deep. This iron firebox is lined inside with four fire-brick pieces, about 10 inches deep, above the firebars, leaving the iron frame 2 inches above them on three sides, but bevelled down to form a plate between the box and the circular opening for fuel. The firebox is 9 inches square, and as much in depth, whilst the rim of iron prevents the fuel dropping into the open spaces between the firebox and the outside of the stove. This small firebox is sufficient to give out a great heat, whilst the open space all round it prevents the outside of the stove from ever becoming dangerously or offensively hot. A small pan is placed below the firebars for ashes and for draught at lighting; but when fairly set to work, and a continuous mild heat from a slow combustion is wanted, the ashpan is shut close, and air admitted by two or three slits half an inch long, and one-eighth of an inch in width.

We have used this old stove for several purposes, and mostly in a surreptitious manner. When we placed it in the orchard-house, we had to make it as inconspicuous as possible. We durst not meddle then with the longitudinal-pipe, and showing anything in the way of a chimney was out of the question. These considerations, and an idea, confirmed rather than otherwise, that such stoves, if sunk somewhat, spread their heat more equally than those standing on the surface, led to our sinking this stove near the front of the lean-to house 11½ feet in width, and sufficiently low to permit the horizontal-pipe and another joined to it to pass from the stove beneath the pathway and outside the back wall, and there terminate in an upright low chimney of earthenware pipes.

The space in which the stove stands after being bricked round on the slant, is 5 feet long, 3 feet wide, and 3 feet deep, leaving plenty of room in front to attend to the stove. The latter was kept black for free radiation, and the bricks kept whitewashed to reflect the heat radiated from the stove. We have reason to

be satisfied with this arrangement, for though the stove is placed in the middle of the house, 75 feet in length, we have frequently tested the temperature of the ends and centre, and in still weather found them within very little of each other.

Now, though we found this stove very useful, we have been thus particular in noticing its details that others may beware of trying long horizontal-pipes, or even those rising a little from the stove as ours did; for in very misty weather we found a difficulty in securing a draught, and when the wind was from the north, we were often obliged to take out the plate outside the wall, which we had left for sweeping purposes, and light a fire there, which, heating the outside chimney, gave us a draught from the stove. The collection of a tarry substance and hard soot in the course of years, in the long horizontal-pipe which the brush passed through without taking it out, helped also to impair the draught. On Wednesday, every man was thoroughly beaten after trying every conceivable plan to make smoke pass from the stove to the chimney, with a northerly wind as it was. This determined us to do at once what, but for the circumstances referred to, we would have done years ago. We had our blacksmith in the morning to drill holes all round the old pipe, and then use the cutting-chisel between so as to sever the pipe 2 feet from the stove. We would have preferred it nearer, but there was a copper band round the pipe at that distance, which we thought would be security for getting it more easily out; for if we had been at all rough the old stove would have dropped to pieces. A few of the garden men did all the rest. The pipe previously passed through a small brick-drain; the sides of this formed a cesspool as it were for the shortened pipe to end in. An old nine-feet cast-iron pipe with a three-inch bore, was set on the top of the cesspool, the other end passing through the roof, a square of glass being removed. The bottom end was secured by two layers of bricks and mortar, the end of the opening filled so as to be easily pulled out for sweeping, and a piece of zinc the size of the large square of glass, with a hole for the pipe, fastened as a square of glass; the fire was lighted, and the stove that would not draw the day before would, with an open ashpit-door, have sent the half-burned shavings out at the end of the chimney-pipe. The whole alteration was done in a few hours of the forenoon, and but for having the three-inch pipe beside us, we would have preferred one of four-inches, or even greater diameter, with a piece of zinc bent over the outer end to prevent the rain or snow falling into it.

Some who have not been satisfied with their small stoves, may now perceive that their want of success, so far as plants are concerned, may be owing to a horizontal-pipe being too long, to the pipe proceeding from the top of the stove becoming too hot, or to the fire-box abutting at once against the sides of the stove and making them almost red hot, which is very destructive to vegetable life, the air being burned and deprived of its moisture and oxygen. For all such iron stoves, broken coke is a good fuel. It is less injurious to pipes, &c., than coal. Cast metal makes the best chimneys. Plate iron is expensive and soon corrodes and wears out.

In the boisterous morning of Friday, when the dry snow was finding its way into the house through every little cranny, the stove, with the consumption of less than a peck of coke, soon raised the general temperature of this 75-feet house to 60°; then the pipe-chimney, which has 7 feet of its length inside the house, was pretty warm; but on the draught being stopped by putting the ashpit-box close in, and leaving only two of the one-eighth-of-an-inch slits open, the upper end of the pipe-chimney gradually cooled, whilst the heat of the stove long remained uniform. The open space all round the firebox renders the bottom of the stove outside almost as warm as the top. We would wish to impress on all who contemplate an iron stove for their little houses, to rest assured that a moderately large one will be truer economy in the end than a small one, and to think seriously of the importance of having the firebox free of the outside of the stove. If the small openings for air are properly managed there is no need of a damper.

We have not yet had the management of one of Hays's stoves, though from what we know of stoves we feel sure they will be very useful, especially with a small pipe to take off the gases, but two things are against them, the price of the fuel and the difficulty as yet involved in obtaining it only in London. For all purposes where only a temperate genial heat is required there is no mode of heating that in economy of fuel will equal that of stoves placed inside a house. When we mentioned 60° above, that was only to satisfy ourselves what could be done quickly in a stormy day. Stoves, if of iron, are best used when the fire heat in the house should only range from 45° to 55° in mild weather, and 5° less in severe weather. With iron stoves large enough, or brick stoves, which are less easily made dangerously hot, much may be done in economical gardening in houses cheaply enclosed with glass.

Iron stoves are better for small greenhouses than brick stoves in respect to the ease with which they can be moved out in summer. One complaint against them is that the sheet-iron pipes generally used so soon wear out. Cast metal cleaned at times would last a lifetime. A reducing elbow to fit into the stove, and the upright pipe fitted into it with cement or good mortar, could be taken out at any time. The over-heating is the chief evil to be guarded against. Where such care and such large stoves cannot well be used, it would be well to surround the stove with a water jacket.

Boilers.—Some time ago we alluded to the waggon saddle-back boiler, one of the peculiarities of which is that there is a pipe at the bottom connecting the two sides at the farther end, so that by one tap you can empty the boiler. A correspondent in praising the terminal saddle-back boiler (which, though we have not seen, we have no doubt is a good one, and so is every fair-sized saddle-back so far as burning all sorts of rubbish of fuel is concerned, if well set), took occasion to point out the defect of the property referred to in the waggon boiler, inasmuch as the pipe between the two sides would soon burn out. This may be the case, though it has not come to our notice. This cross pipe placed at the bottom would always be at the coolest part of the furnace, more especially as it would be beyond the fire bars, and, therefore, little liable to a knock from the poker. In some cases that we have seen this end pipe is also covered with a sloping fire lump, to give a quick draught round the sides of the boiler. Be this as it may, we think it of importance that by such means, or by the improved terminal boiler, or by having a tap at each side of the saddle-back, there should be an opportunity of emptying both sides of the boiler at times. We have had some experience in tinkering in a simple way the sides of saddle-backs, after they have been worn out in places, and we have uniformly found that they first gave way on that side where there was no tap, and if the boiler was so far gone as to compel removal, we as uniformly found a lot of mud collected at the bottom of that side. However clean the water used a sediment will form in time, and in many cases water is sometimes used for this purpose with less attention to its state than ought to be exercised.

Bursting of Boilers.—Since January, 1861, we have not heard of more boilers giving way than this season. When worn out by gradual decay we cannot speak properly of a boiler bursting; but such no doubt is the case when the failure of the boiler is attended with the throwing up of the brick setting, &c. There can be little question that in such a case steam has been generated. "How," says "Inquirer," "can steam be generated in a boiler kept regularly supplied with water?" How, we might ask, could air pass into such a boiler? How can it collect in pipes pretty constantly supplied with water? how become as firm and incompressible as iron or granite? It will be obtained from the water itself; it will find an entrance whenever from over-heat and expansion there is a loss of water, and even from contracting into less space as it cools. "Inquirer," however, supplies a sort of confirmation that in his case steam was the destructive agent. He says that "to produce heat enough the water in the pipes was boiling hot, the fire was very strong, and the boiler very hot." As the supply-cistern was very elevated and communicated with the top or nearly the top of the boiler, the pressure of the water and the great heat below the boiler would be very apt to cause air or steam to accumulate close to the iron of the boiler; and this iron, from the water not touching it, would become very hot, and when from a charge the water again came in contact with the over-heated sides of the boiler, steam would be so quickly formed that there must either be a rapid overflow of water or the boiler from the pressure must give way. When some of our correspondents told us, as in a late case, that the water was thrown out so fast from the supply-cistern that they had to keep almost constantly supplying it, and then could not keep it full; there was more than the increased bulk from the expansion of the water, and but for the running over, or boiling over rather, there would have been a bursting. The remedy is just as in the case of stoves; have enough of boiler and of piping that there may never be any necessity for having the water near the boiling point instead of beyond it.

Wrought Iron and Cast Metal Boilers.—Which are the better? inquire many—that is, which are the more lasting. This is a

matter we cannot decide. So far as our experience goes, the cast metal would carry the day. We know some very common cast metal boilers which have stood their work more than thirty years. We have seldom known a wrought iron saddle-back last much longer than sixteen years—fifteen years might be looked upon as a fair average; some may stand longer, and others go before that time. Our experience and observation point to cast iron as the most durable. As it is a matter of some importance, for there is generally much trouble when one gives way, we hope correspondents will give the results of their experience. We find, too, that, unlike some other of our servants, the more regularly they are worked the longer they will last, as a general rule, and hence the boiler for a greenhouse or a lean-to forcing-house will not last so long as one more constantly used.

The general work, potting, cutting-making, changing plants, and moving Strawberry pots, &c., has been so like that of previous weeks that we will defer particulars.—R. F.

COVENT GARDEN MARKET.—March 27.

With better weather we may expect some improvement in the tone of business; but at present there is nothing in the character of either supply or demand that merits particular remark. Continental supplies comprise Radishes, Lettuces, Endive, Artichokes, Tomatoes, and Kidney Beans, and reach us in good condition. Forced fruits of Pines and Strawberries may be had at rather lower prices.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

Books (*A Young Beginner*).—Thomson's book on Grape Vine culture is a good practical work. We know of no separate work on Melon culture. Mills on Cucumber culture is a good work. (*An Amateur*).—"The Vine Manual," a new edition just published, which you can have free by post from our office if you enclose thirty-two stamps with your address. (*A Bud*).—"Thompson's Gardener's Assistant" is an excellent work. You must have more practical knowledge before you can write for the instruction of others. (*M. S. D.*).—The want which you truly point out will be supplied at the close of the present year. The work is preparing. (*J. K.*).—You can have "The Modern Peach Pruner" free by post from our office if you enclose 3*s.* 8*d.* in stamps with your address. Berkeley's "British Mosses" is good. It contains twenty-four plates, and its price is one guinea.

Everlasting (*W.*).—The two flowers enclosed are different forms of Gnaphalium arenarium, or Sand Everlasting. "French Lavender" is Lavandula stæchas of botanists. It has been extensively grown not only for its fragrance but as a medicinal herb.

Temperature of Greenhouse (*Ignorance*).—Your question is far too indefinite for us to answer. If you enclose seven postage stamps with your address, and order "Greenhouses for the Many," you will have the book sent you free by post. It will give you probably information adapted to your wants.

Aucuba Japonica (*R. L.*).—If you place a male plant of Aucuba japonica by the side of the old variegated sort it will enable the latter to produce berries. Those plants which have borne berries this year will not continue to do so without the pollen of the male.

Granite Sand (*Mrs. C. Galloway*).—Fine granitic sand, such as you find on the banks of the Dee, if not soaked by sea water, is excellent for Ferns and Heaths. Even if impregnated with salt from the sea this may be removed by two or three washings in fresh water.

Grammars Potatoes.—Mr. Frederick Gill, of the Dorset Nurseries, Blandford, sold four hundred sacks of the sorts named by me for eating purposes, and has none left. This notice may stop fruitless applications, of which he has had many.—W. F. Radclyffe.

Sulphate of Lime as a Manure (*W. J. L. Farm*).—We are quite inclined to believe the statement of your friend, that his sugar plantations in the West Indies have produced much larger crops since he applied sulphate of lime (gypsum) to the soil. It is composed of forty-three parts sulphuric acid and thirty-three parts lime. It is a constituent of Lucerne, Saintfoin, Clover, and of many of the Graminæ, the Sugar Cane being one of them. It is also a constituent of Turnips, Potatoes, and Buckwheat, and to all these crops it has been applied advantageously. No more than four or five bushels per acre, sown by hand, are required. One farmer has recorded, that of Clover hay, his land manured with gypsum, produced three tons per acre, and the land un-gypsumed only one ton.

Zinc Cisterns as Flower-pots (*W. Nunn*).—As we observe that our Myrtles, Coronillas, Vines, Peaches, Nectarines, Apricots, Figs, &c., are becoming too large for their pots, we are tempted to envy you the possession of the fifty circular zinc cisterns, 16 inches in diameter, and the same in depth. Excellent pots, indeed, they would make to shift the above into next October, by first taking the precaution to bore in the sides of each, close to the bottom, three circular holes of about an inch in diameter, and in that case a central hole in the base may be dispensed with; the side holes are better for the exclusion of worms. The outside may be painted stone colour, and be made to resemble stone by sand being dashed on the paint whilst it is wet, or the appearance of terra cotta may be given by putting on a coating of red paint and dashing sifted brick-dust against it whilst the paint is wet.

Tricoloured Zonale Pelargoniums (*J. W.*).—Your tricolor Zonales are the finest of the kind we have ever seen. They have all a rich golden, well-defined margin, with a decided green centre. In Florence we have broad, distinct maroon zone, fringed with dark crimson; the leaf is large and very handsome. Aurora Borealis is a somewhat smaller leaf, and with a larger and paler green centre, a narrower zone, and its colour a mottled mixture of bright crimson and maroon, the maroon prevailing. Fanny is a smaller leaf still, with a small pale green centre and a broad very lively bright crimson zone, with a few mottles of pale maroon. Northern Star is much like Fanny, but with less maroon in the zone. Beauty of Huntreyde has a large green centre, with a pretty narrow zone of mottled crimson and maroon. Letty Wills is also a small leaf, the gold margin rather paler than in the others, and with somewhat of the same zone as Beauty of Huntroyde, but with a smaller centre.

Aspect of Greenhouse (*W. Bradford*).—The difference is so slight between a south-eastern and a south-western aspect that we should be guided in our choice by other considerations, such as appearance, facility of access, &c. If all these are matters of indifference, then give the preference to the south-western aspect.

Pollen of the Male Aucuba (*C. T. H.*).—Shake the pollen on to dry tissue paper, fold it up like a medical packet of powder, then put it into a wide-mouthed phial which has been well dried; cork it tightly whilst warm and keep in a dry place until required. The seedlings will come very various, both green and variegated.

Growing Potatoes on the Ridge and Furrow System (*J. Currie*).—Suppose that the ground has been half or bastard-trenched for a few weeks, and is lying quite even upon the surface—viz., the top spit and crumbs of the first trench, a yard broad, were cast or wheeled to where the ground is to be finished, in order to fill up the last trench. The bottom spit of the first trench, or subsoil, must then be broken up with a Parkes's steel fork and kept down; then fork the top spit of the next trench on to it, and cast out the crumbs clean with a shovel on to that, and so on, working in raw manure through the whole body of the soil only in the autumn. Now measure out the ground for the Potatoes, and strain a line across, row after row, to pegs where the rows are to be. Place the sets upon the surface of the soil at quite a foot distance for the earlier, and 18 inches at least, if the ground is good, for the late and larger-topping sorts. Then readjust the lines to the full width, or, what is better, rather wider than a shovel—say a foot, to mark out the trench centrally between the two rows of Potatoes. Cut down with a spade, and rather slanting inwards, to the full length of the lines, in order to leave the sides of the trench even, and to form as it were a rather pyramidal base to the ridge. Then dig, and cast out every other spadeful of earth, right and left, on the shoulders of the corresponding ridges, by which you avoid plumping the soil on the shoots of the sets in the centre, and leave that part hollow to become filled directly with part of the crumbs through the agency of the shovel, and cover the sets about 3 inches deep. In about a fortnight afterwards shovel the crumbs, or loose soil, clean from the trenches, which will fill up the centres of the ridges, and leave them about a foot broad, flat upon the top, and gently sloping at their sides, about 18 inches deep to the bottom of the trenches, and leave the Potato sets covered about 6 inches deep. Should a propitious season occur, and the crop be free from the disease, nothing further will be required, except picking off the blossoms of those which are disposed to berry, and clutching away any weeds which may be showing themselves too prominently till the Potatoes are ripe. Mr. Fish gives excellent advice for a light soil and open situation at page 183.—Upwards and Onwards.

Sulphur and Lime (*Inquirer*).—When these are boiled together in water they unite and form what chemists have named bi-sulphuret of calcium. Calcium is the metal which united to oxygen forms lime. The bi-sulphuret is fatal to insects and injurious to the leaves of plants.

Heliotrope Unhealthy (*A. H. J. L.*).—The plant, judging from the stem and leaves you enclosed has been seriously damaged by the syringing with the Gishurst solution. Your remedy will be to have the plant well syringed, and repeatedly, so as wash it off. The solution has been far too strong, and we do not perceive the reason for an application of Gishurst to a plant having, as this has, such a woolly leaf and stem. We would cut the plant in closely, or every shoot to within an inch or two of the old wood.

Forcing Lilies of Valley (*X. Y. Z.*).—Our practice is to take up those roots that have large plump crowns, and such only, potting them in a compost of rich turfy loam, and placing them in a house with a temperature of 40° to 45° for a fortnight, and afterwards until they bloom in a temperature of 50° to 55°, and not exceeding 60° at night, affording them a position near the glass and plenty of water. We never fail to have a plentiful supply of bloom; but we pot none other than the flowering roots, which is different from taking up patches from the borders, more than half of which are by far too small and weak to flower, and, indeed, have no flower-bud formed; for were you to cut a crown open you would see the bud, if any. Pot none but the large crowns, and put them in pots or pans at about an inch apart. The price of Keane's "Out-door Gardening" is 1*s.* 6*d.*, or free by post 2*d.* extra.

Moss on Lawn (*F. I. C.*).—It is hardly possible to free your lawn entirely from moss, nor do we think a little any great harm, but rather an advantage, as it is much pleasanter to walk upon. The chief causes of mossy lawns are a poor soil and its being undrained. We would recommend a dressing of rich soil or very rotten manure, first scratching the lawn with an iron rake, and then applying the salt at the rate of half a pound per square yard; finally dress with the compost, not covering deeper than a quarter of an inch. The first heavy rain will wash it in; when the ground is dry roll well, sowing previous to rolling 24 lbs. per acre of renovating lawn grass seeds.

Weeds on Walks (*Idem*).—If your walks have become dirty at the surface, which is a prolific source of grass and moss, we would advise their being now picked up and turned, giving them a sprinkling of fresh gravel. You will, if you roll well, have a splendid walk until half the summer is over, and by the time weeds are troublesome one dressing of salt will serve the whole season. 3 lbs. per square yard are required to destroy weeds on gravel walks effectually, and that quantity makes the surface so damp that it is by many objected to; and salt causes the gravel to wear much more quickly, and so encourages the growth of weeds: hence the prevailing opinion, weeds on walks come thicker after salting. The time to salt walks is when there are weeds; and its application will be necessary in April or May, and again in July or August, putting it on during dry weather, dependant, of course, on the season.

Planting Flower-bed (*Idem*).—Your proposed planting of a circular-bed by using Silver-edged Pelargonium, a double row for edging, then a double one of Stella, and filling the centre with Purple King Verbena or Perilla would not answer well. We would have the centre some silver-foliaged plant as Centaurea argentea, C. ragusina, or Cineraria maritima, the flowers being pinched off the variegated Pelargoniums. A very effective bed may be made by using Cerastium tomentosum, or C. Biebersteini as an edging, then Purple King Verbena, next yellow Calceolaria, filling in the centre with Perilla.

Pinching Show and Zonale Pelargoniums (*A Constant Reader*).—The Show ones may now be pinched if necessary, but not later if you wish them to flower at the end of June, and the Zonale not after the third week in April. It is better to retard than force them into bloom.

Insects in Old Tan (*A. B. A.*).—We presume the insects in the tan, over the dung hotbed, are some kind of mite that will do your plants or cuttings no harm, but disappear when air is given.

Viola cornuta from Seed (*Idem*).—There is no more art required in the raising of this plant from seed than that of any other of the Pansy family. We simply drain a pan well, fill it to the rim with a compost of sandy turfy loam two-thirds, and one-third leaf mould, and, making the surface smooth by patting it gently with the bottom of a flower-pot, sow the seed, and just cover it with fine soil. A gentle watering is then given, and the pan placed in a gentle heat, as that of a Cucumber-frame, or hotbed with a temperature of 65° or 70°, assiguing them a position near the glass. The plants come up well, but we have had failures through the seed being bad.

Tea-scented Roses in Greenhouse (*Idem*).—We advise the placing of all kinds of Roses out-doors in summer, as under glass they are subject to red spider; besides, they are benefited by a brief sojourn in pure air and refreshing rains. Put them out in June, and house in October.

Estimate of Coal for Heating Garden Structures (*Waste Not, Want Not*).—Yours is a very difficult question to answer, as the quality of the coal is a serious consideration, some kinds lasting half as long again as others. We presume you burn slack coal, and in that case, 1 ton per week for the summer, and 2 tons for the winter season would be a fair allowance, or 78 tons per annum, the cinders from the house being added thereto. The usual allowance for a gardener's cottage is 5 tons of best coal per annum, but the allowance varies; for instance, in the south 4 tons only, in the west 5 tons, whilst in the north 6 tons are allowed, and in many places where coal is cheap, there is no limit to the quantity.

Planting Potatoes (*Henry Bover*).—The soil being light the sets may be planted in drills deep enough to allow of these being level, earthing-up after they have been well hoed and cleaned. They will, no doubt, answer well, but if the soil be heavy, or wet, it is better to plant in ridges.

Linum flavum (*Idem*).—It is a perennial not flowering the same season as sown, unless sown and forwarded in heat.

A Yard of Netting (*A Beginner*).—When we order netting 2 yards wide, we expect it when one side is fastened to the top of a wall under the coping to hang down 6 feet, and if it do not we return it. A yard of netting is, when the two sides and ends are fastened, to cover 9 square feet, or 1 yard superficial, and to cover 10 yards square, 100 yards of netting only are required; but some allowance must be made for slack and elevation from the ground, which in the covering of fruit bushes to protect them from birds, very often take up more than double the netting necessary to cover the ground. Netting is usually sold by the lineal yard.

Netting for Doors of Orchard-house (*E. S.*).—We do not know of anything that could possibly be more light, airy, and elegant than Haythorn's hexagon netting for keeping out wasps and birds. This tacked to frames, providing the frames were hung to the posts with hinges, would not be inconvenient. It is advertised in our columns.

Seed Sowing (*Henry Bover*).—The plants you name may be sown and treated as you propose in a cool greenhouse with every prospect of success, only keep the soil moist, and when they are up give plenty of air and a position near the glass.

Ixora coccinea Leaves Browned (*A Common Cabbage*).—It is produced through moisture lodging on the leaves, the plants being kept in too low a temperature. If you were to give the plant the benefit of a hotbed of from 75° to 85°, and a top heat of 65° to 85°, with plenty of moisture, but not through syringing overhead, with a moderate amount of ventilation, and a position near the glass, we think the leaves would not brown.

Vines at Back of a Greenhouse (*H.*).—The Vines will never thrive so long as they are overshadowed by climbers, and the back of a greenhouse is no place for them. They should have a position on the roof. Allow but one shoot from a Vine, train it 15 inches from the glass, allowing it to grow until it reaches the limit of the space allotted to it, then stop it. The laterals should have their points taken out at the first leaf or joint, and again at the second, cutting them close to the cane at the commencement of October. Water well now, and again when necessary, keeping well watered until September, then diminish the supply, giving none after September. Syringe morning and evening up to August, but early in the morning, and let the foliage be dry, or give air before the sun shines powerfully upon them. You may top-dress them now with an inch or two of rich compost. Water will be required about once in every ten days—a thorough soaking.

Camellias for Market (*A Constant Reader*).—You will find none equal to the old Double White, or Alba plena, and Fimbriata, of the whites; Bealii (Leeana superba), and Chandleri of reds; Sacco nova and Augustina superba, of rose; and of the striped shaded sorts, Storyii, Jenny Lind, Madonna, and Sarah Frost.

Roses for Forcing (*Idem*).—The Tea-scented and Hybrid Perpetual are the best, a list of which you will find at page 157 of the present volume.

Old Plants of Tom Thumb Pelargoniums (*A Subscriber to the Journal*).—Your old plants may at once be placed in the hotbed, and when grown sufficiently take cuttings from them, but we fear they will not grow sufficiently, being now no more than alive, to furnish cuttings that will be available for the present season. You can raise cuttings of Verbenas in your hotbed, particulars for which, as also for Pelargonium cuttings, you will have read in last week's Journal.

Pruning Camellia Root (*A Constant Subscriber*).—It is not necessary to root-prune Camellias to keep them in small pots, as no plant will thrive longer in the same pot than Camellias. We say, Do not root-prune them, but you may remove most of the old soil, potting again in the same size of pot. If you were to give the Primulas more heat and moisture they would throw the truss well up above the foliage. All they require is more liberal treatment.

Genista not Flowering (*Idem*).—Afford a compost of turfy sandy loam, a cool airy situation in the greenhouse, and a position near the glass, with water, so as to keep the soil moist; it will assuredly flower, being the freest of flowering plants. Do not allow it to suffer for want of water, and, on the other hand, water only when necessary when the buds are swelling and the plant is in flower.

Melons to Ripen in August (*Wyeside*).—The easiest way to ripen Melons in the first fortnight of August in a pit with the help of manure heat is to have the manure sweetened, at least the upper portion of it, by the end of April; have the bed made and the soil in by the first week in May, and turn out strong plants, but young, in the soil as soon as warm. Let the plants be stopped as soon as they make the third rough leaf, and of the shoots that come from the axils of the leaf select two, nipping out all others. If your light is wide plant three plants singly and at equal distances; if narrow, say 3 feet, only two plants. Of the two shoots on each plant train one to the back and one to the front of the pit. Do not stop at all until the shoots are within a foot of the back and front, then nip out the point of the shoot. As the shoots are growing, every bud that appears at the axils of the leaves, which buds would be lengthened into shoots, should be neatly taken out with the point of a knife, until you reach to within 6 or 8 inches of the point of the shoot stopped as stated above. This will leave a number of buds near the end of the shoot that will lengthen into secondary shoots, and on these the fruit will generally show at the first or second joint, and they should be stopped at the joint above the fruit. Care should be taken to set the blossom, and to keep a warm, dry atmosphere at that time. By the above simple plan the pit will not be crowded with shoots, and there will be a good strength in the plants to set the fruit when it shows. A volume could scarcely say more definitely on the subject.

Flower Garden Plan (*Jos. S.*).—Your garden will look very well, and the central part at least will have all the openness of the lawn at Tingrith, alluded to last year. We like your proposed arrangements; but as you have the plants we think you would improve the whole by having a band of Cineraria maritima round No. 1 in centre. We would put a band of orange Calceolaria, fringed with Lobelia, round 6 and 7, Gazania round 8, and Cerastium round 4 and 5.

Cucumber for Ridge Growth—Fowls Trespassing (*A Constant Reader*).—The old Long Prickly is the best useful variety, either for growing in the open air or in a cold frame. If fowls creep through your thorn hedge have some galvanised wire netting placed all along the bottom of the hedge. If they fly over have similar netting fixed to supports along the top of the hedge. If the fowls continue to injure your garden after having given notice to their owners, you could recover compensation in the County Court.

Iris Kempferi.—"A. R." informs us that he has bloomed it for some years past; he will oblige us by stating whether he considers it a very distinct and desirable flower.

Tiffany (*Dolores*).—Apply to Messrs. J. Shaw & Co., 29, Oxford Street, Manchester.

Pears at Eighteen Guineas a Dozen (*Hyacinthus*).—The Pears you allude to, as shown at the fruiterers' in Covent Garden Market, are imported from France, where they are grown against a wall, very few allowed to be produced on the tree, and other modes adopted to promote grossness. The fruiterer called them Belle Angevine, but the true name is Uvedale's St. Germain.

Heating a Greenhouse (*H. J. S.*).—We conclude that the pipes heat the slates above them, but that the heat does not pass into your six-inch bed of tan and 4 inches of soil above that, so as to make it impossible to obtain more than from 60° to 65° of heat in your bed for propagating, &c. With such a heat in the bed, what is the heat in the house? because if much lower, still the bed will partake of the general temperature, unless you cover the bed with hand-lights, small frames, &c. If the slates become warm enough we have no doubt that the tan is the cause, not because it is too close or is at all inferior to cocoa-nut fibre, for in similar circumstances that would be the same, but because it becomes dry next the slates, and then refuses to conduct the heat. Before you try your perforated zinc, clear out the bed and place on the slates 2 inches of rough clinkers, rough cinders, and an inch of fine washed gravel, and on that the soil. Have some small drain-pipes standing upright in which you can pour water at pleasure to wet the clinkers and slate, and stop the opening to keep in the steam, and we shall be mistaken if you have not plenty of heat. Of course, if the pipes do not heat the slates it is either owing to the heat not being strong enough, the pipes not being close enough to the slates, or the chamber in which the pipes are contained not being close enough. That chamber should only have a few slit openings near the floor. Let us know.

Peaches, &c., in a Greenhouse (*An Inquirer*).—In your span-roofed house, with a pit on each side, you may grow Peaches, Cherries, and Figs admirably in pots, but the first two should have very little of the bottom heat. If for them chiefly, it would be as well, by means of openings, to let the bottom heat out into the atmosphere of the house, and then the Peach roots may be 5° or more warmer than the atmosphere. The use you can make of the pits afterwards depends on the earliness of the time at which you bring the Peaches in and the due ripening of the wood afterwards, and moving them out in a dull day, so as to give no sudden change at first. Then you might have Melons, Cucumbers, and other things in the same pits.

Flower Garden Plan (*Inquirer*).—We presume your plan is on gravel, or the paths between the beds will be too narrow. For a beginner your plan and proposed planting do you great credit; so far as the materials to be used are concerned, we can find no fault, and when all are in bloom it will look well. As a lasting group you will fail to have a continuous mass of bloom from using so many Stocks, Asters, Carnations, Pinks, Pansies, and Chrysanthemums, and there will be in some cases a defect in the respective heights—thus, Eschscholtzia tenuifolia would make a better edging to Phlox Drummondi than a centre to it, as the Phlox is much the taller growing. If your position is cold we doubt whether Portulacas will make a good edging to Verbenas, and they show little in dull weather. They flourish on a warm knoll. On the same principle we doubt if Acroclinium and Rhodanthe will make good edgings to Asters. Some of the Nemophilas and Silenes would be more sure; but it is well to try. The Rhodanthe, is beautiful in warm sheltered places.

Names of Plants (*M. Oakley*).—We cannot name plants from single leaves. (*A. B. C.*).—It is a Mammillaria, but the species cannot be identified from such a small specimen. (*A. W.*).—There are two forms of leaves on Retinispora leptoclada, and those you sent may be the young form; but we cannot be certain from such a fragment.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 26th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

NOTES ON FANCY PIGEONS.—No. 7.

FORMER WRITERS ON THE SUBJECT—RECENT WRITERS.

DELAMER—EATON—BRENT.

After the publication of Windus (1802 and 1804), there was not, so far as I can learn, any special work published for many years on the subject of fancy Pigeons, or, rather, any worthy of mention. In books on poultry Pigeons were indeed mentioned briefly, and also in books on natural history, but rarely was more given than the names of the fancy birds. Windus, therefore, remained the authority on the Almond Tumbler and its short-faced brethren, and Daniel Girton sufficed for the general fancier; nor could it have been better, as each author was the best of his kind. Girton was frequently reprinted, and well-worn copies were lent from one to another by the humbler fanciers, and thus Pigeon knowledge by book was kept up. Years rolled on, and so things remained. Pigeon love in those præ-railway, and therefore home-keeping and home-enjoying days, was ardent, but the knowledge of the fancy was learned orally, or from the two books just named; but one thing is certain, that never were better birds bred than at the time to which I allude.

In 1851 appeared a well-got-up volume by Murray, entitled "The Dovecote and Aviary," by the author whose name stands first at the head of this paper. This writer was a scholar, a naturalist, and master of a very attractive style of writing—indeed, no one of equal literary powers had as yet handled the subject. The engravings of the book were not equal to the letter-press, being evidently the production of one who did not understand fancy Pigeons, and no one but a fancier can accurately and justly draw a fancy Pigeon. Very pleasantly indeed is "The Dovecote" written; free and picturesque was the pen of the author—more than that, the work was original to a great degree; but the writer was rather a scholar and naturalist than a fancier, indeed he laughs at what he calls "the ultra fancier." Thus he says, "And now for the Tumblers, the prettiest of the pretty. In approaching them one had need have more courage than Master Slender in the presence of sweet Anne Page; for the dealers and ultra fanciers are standing by, like so many duennas and chaperons over a supposed veritable heiress. But give me in its unsophisticated and vulgarly bred state the pretty little Tumbler." And elsewhere he speaks of the Almond and other high-class Tumblers as "the much-valued specimens of hereditary deformity, with spherical heads and no beak." Now this is too bad, for high-class fancy Pigeons are to common-bred birds what florists' flowers are to ordinary flowers of the same kind—far superior, and advanced by care and pains to a higher state of beauty. Indeed "ultra fancier" there cannot be any more than an ultra florist; each is only a striver after greater excellence, and produces a higher class of beauty.

The author of "The Dovecote" makes a mistake concerning Kite Tumblers which needs correction. They are not, as he says, "those Tumblers which are self or whole-coloured—*i. e.*, all black or all cinnamon," but black birds with a strong glow of red in their flight feathers, and they are bred from Almonds, which latter—hear it not, ye short-faced fanciers—he calls "dirt-coloured when seen from any distance." The author of "The Dovecote" does not appear to have ever seen Moore's "Columbarium," as he speaks of "the excellent treatise on Pigeons attributed to Dr. Moore, from which subsequent pamphlets have taken so much without acknowledgment." He had, however, seen Girton's book, which he quotes, and specially and rightly states is "without date."

By the way, I may remark that I have learned a little more concerning Girton since reviewing his book. The Catalogue of the British Museum assigns to it the date of 1800, but a mark of doubt (?) is added. The compiler of the catalogue was right as to his doubt. Alexander Hogg was the publisher of Girton, and he was also a noted printer of books sold in numbers; he published a family Bible with illustrations by Benjamin West, who came to England from America in search of employment in 1763, and worked for the printers, for he was then unknown to fame, and continued to be until George III. smiled upon him. Now, putting this fact and the appearance of my copy of Girton together, and that Girton is referred to by Moore and mentioned also by name in the Treatise, I have little doubt as to placing his date at from 1765 to 1770.

While mentioning Girton for the last time, I cannot refrain from quoting a pleasant notice of his work in that marvellous

production of an omnivorous reader, "The Doctor," by R. Southey. In the one-volume edition, page 350, in a chapter entitled "Facts and Observations Relating to Onomatology or Names," Southey, after speaking of the different names of gooseberries, apples, pears, &c., goes on to say, "Hath not Daniel Girton, of Bucks, in his 'Complete Pigeon Fancyer,' wherein he points out to the gentlemen of the fancy the foul marks and real perfections of every valuable species of fancy birds and Toys which in his time were bred in England, France, and Holland: hath not Daniel Girton I say (though Boswell thought that a sentence so formed as to require an 'I say' to keep it together resembled a pair of ill-mended breeches, and candidly acknowledged the resemblance in his own—the sentence I mean he was penning, not the breeches he wore). Hath not Daniel Girton, I say, particularly enumerated in his title-page among the varieties of such fancy birds 'Pouters, Carriers, Horsemen, Dragons, Croppers, Uplopers, Pouting Horsemen, Fantails, Chinese Pigeons, Lace Pigeons, Tumblers, Runts, Spots, Laughers, Trumpeters, Jacobins, Capuchins, Nuns, Shakers, Helmets, Ruffs, Finikins, Turners, Barbs, Mahomets, Turbits, Owls, Smiters?' concluding the imperfect enumeration with an '&c.'" N.B.—Southey must have possessed a copy of Girton, and written with it before him, as the order of the names is exactly as given in the title-page of "The Complete Pigeon Fancyer."

Returning to "The Dovecote," the author of which was a Pigeon lover rather than a Pigeon fancier, and who for real fancier knowledge frequently quotes the older writers; still we may be glad that such an original work was written by one gifted with a charmingly descriptive style, who raised the taste for Pigeons, and proved that these beautiful birds, despised too frequently by the naturalist and the gentleman, need not necessarily be associated with the lower orders of society. It is said that in olden times every fourth Dutchman was a Pigeon fancier; perhaps something of this kind may yet take place in England. Every one needs a hobby, and what prettier things can be found to constitute one than fancy Pigeons? In "The Dovecote," now I believe out of print, we find the first mention of the Archangel Pigeon. An abridgement of the work containing the more practical portions has been published by Routledge in his series of "Books for the Country." It forms the first part of the volume entitled "Pigeons and Rabbits," by E. S. Delamer.

I now turn to one of the curiosities of literature, "The Treatise on Fancy Pigeons" by J. M. Eaton, and bearing the date of 1858. This edition includes his book on the Almond Tumbler, first published in 1851. I have called it a curiosity in literature, and indeed it is—so strangely written, so wandering, so odd; sometimes we laugh with the author, more frequently we laugh at him. He is a most enthusiastic Pigeon fancier, going far beyond the bounds of ordinary enthusiasm; then he mixes all sorts of things in his book; yet, though style, manner, and matter are often of the queerest description, no one can doubt the thorough knowledge which the writer possesses of his subject. The coloured illustrations by Wolstenholme are most excellent—the poor birds at length had full pictorial justice done to them. The same may also be said of the twelve large coloured portraits of perfect Pigeons (alas! where are the realities?) life size, published also by Mr. Eaton. I shall never forget the delight of an old fancier to whom I showed the pictures in Mr Eaton's book, and who had always deplored the ugliness of Pigeon pictures and their want of truth both to nature and fancy.

The plan of Mr. Eaton's book is this:—He publishes Moore's work with notes by himself and others, some notes excellent, some extremely funny. Thus he brings the fancy down to the present time. Then is added as a second part "The Almond Tumbler," which is in fact, as I have before stated, the work of Windus with additions, some acute and sensible, others in the odd vein. Manifestly the writer had but few early educational advantages, and therefore I forbear to make extracts or further to criticise. A better-arranged edition much condensed, as the writer himself seems to think, would be an improvement, as also omitting the coarse parts and expressions, now printed in full from the older works, but which a modern and better taste decidedly disapproves.

And now I come to the last-published and the best book on fancy Pigeons—"The Pigeon Book," by B. P. Brent, a name respected in these columns; for who, being a Pigeon fancier, has not profited by our deceased fellow contributor's clearly expressed and sound advice? It may at once be said that Mr. Brent did not hold the picturesque pen of the author of "The Dovecote," that he did not write what all would read for amusement, but that he strictly wrote to give information, and he gave it in plain words; and his work is by far the most complete on the Pigeon subject generally, a work to which to appeal and refer. This book forms the fourth original one on the subject—"The Columbarium;" then that of Windus; then "The Dovecote;" and, lastly, "The Pigeon Book;" but both the second and third must yield the palm to the additional information given by Mr. Brent. His residence on the Continent caused him to be able to introduce to the English reader a great number of German and French Toy Pigeons, which had never been previously noticed. Among these were Carmelites, Suabians, Hyacinths, Porcelains, Swiss, Stomachers, Priests, Sea Swallows, &c.

Mr. Brent arranges Fancy Pigeons very sensibly, in one division taking in all birds having certain strongly defined points or properties, such as Carriers, Tumblers, Pouters, Jacobins, &c., and then in a second division, he comprehends those Pigeons which are mere birds of feather, in which shape is little or nothing; and this property, feather, once lost they become only common Pigeons. In this class he places Suabians, Priests, Shields, and the general mass of German Toys. In addition to much useful information concerning management, feeding, &c., Mr. Brent was the first to arrange a prize list, placing the original colour of each variety first, and then also giving the particular fancy points of each breed, thus being a guide to purchasers, owners, and judges. Whoever wants good sense and correct guidance on the Pigeon subject, let him turn to the pages of Brent.

I have now traced fancy Pigeon literature from the first known English writer to the last, and as far as I know I have not omitted to notice one worthy of remark. I shall now turn to my own connection and experience with fancy Pigeons. It is an old love, and from which I have never even desired to be off.—Wiltshire Rector.

CROSSES IN DARK BRAHMA POOTRAS.

Having never had any communication with Miss E. Watts, I was much gratified to read her remarks last week on Brahma combs, and to see so entirely independent a corroboration of my opinion that the shapeless combs we now so often see were derived "primarily from the various crosses which have been attempted with the idea of improving the breed, and since perpetuated by want of care." The only two of such crosses which now demand special notice are those with the Cochin and Dorking, both of which linger unsuspected in many Brahma strains, and a few words may not be useless with regard to their detection.

I should, however, premise in explanation that I am no opponent of judicious crossing; I have a strong opinion that by scientific experiment in this direction, with subsequent careful selection, we might obtain a fowl with all the size, hardiness, and unequalled laying qualities of my favourite breed, combined with the edible excellence of the Dorking; but such would be a new fowl, and should be shown as such. And if I admit, also, that many existing breeds have been greatly improved by a cross, I contend that in such cases all traces of the cross should be thoroughly eradicated before the fowls are shown in their old name. For instance, if it be true, as I believe, that Dorkings were raised to their present standard of size by a cross with the Cochin, and with great advantage to their constitution, it is equally true that every trace of the cross but size is effectually gone. Such is not the case with the crosses I am now considering in the Brahmas.

The cross with the Grey Dorking has arisen from two motives—the one being a desire to improve the form and table qualities of the breed, and the other to give that indispensable requisite in a prize pullet—a dark breast. One well-known yard, which, of course, I cannot name, has specially sinned in this latter respect. Yet, whilst I know that the obtaining a darkly pencilled breast has often been the motive of a Dorking cross, I cannot agree with Miss Watts in her inference that all the darkest birds are thus tainted; for Mr. Teebay was a most inveterate antagonist to any Dorking taint in a Brahma, whilst the hens he used to show were even darker than any we see now.

The Dorking taint shows itself in several ways. A large, coarse, cruel-looking head is one pretty certain sign, which is seldom absent. White-legged pullets will also appear from time to time in every yard thus contaminated, and such legs are an

infallible sign of Dorking blood, though, of course, not to be looked for in most of the birds. There will also be, in all probability, a great want of the characteristic "cushion," causing a long back, and the "fluff" will be more scanty than in pure-bred birds; and lastly, whilst the pencilling on the breasts of pure-bred Brahma pullets assumes the form of more or less perfect semicircles, one within the other, the markings on the breast of a crossed bird often appear in the shape of straight streaks or lines in a downward direction, more or less mingled with the concentric Brahma pencilling. A red colour will likewise be usually discernible, but is by no means decisive, as it will also occur in quite pure-bred birds. The cruel head is the best sign, as it is the last to quit: and did I know, in fact, that there had been a Dorking taint in a yard, and found the heads of the pullets small, taper, and gentle in expression, with good combs, I should regard the strain as effectually "bred out" or eradicated. The faults in shape and colour are less decisive, and will vary with the amount of alien blood, but a white leg is absolute proof. The centre division of the comb will also, in all probability, be thick and blunted, and the whole comb in the hens be too large and thick, even more in proportion than is seen in the male birds, which also, however, will nearly always have combs much too large and fleshy, and with the characteristic triple character much obscured.

Scantily-feathered shanks will likewise be very often found in Dorking-crossed Brahmas, and are frequently owing in reality to this cause when attributed to a fear of vulture hocks. Single birds scantily feathered will occur in any yard, and if very good in other respects, may find their way to the show-pen; but where I have seen whole pens of scantily-feathered birds, I have rarely failed to discover other traces of impurity in the strain.

The Cochin cross I believe to have likewise arisen from two causes; the first being the original scarcity of breeding-stock, which led to crossing with the nearest-allied race in order to increase the produce as quickly as possible; the second being a desire to increase the size of degenerate strains. The first motive needs no condemnation; of the second I will only say that the expedient is totally useless, as a well-bred Brahma cock that has been properly reared is both larger and heavier than any Cochin that ever was seen. In some cases, also, a cross with the Partridge variety of Cochins has been employed to give more pencilling to the breasts of the pullets.

This cross is difficult to detect in specimens picked out for exhibition, but greatly mars the beauty of the general produce in the yard. A narrow and deficient breast will, however, be often apparent, and is an almost infallible sign, though, of course, ill-shaped birds will occur in all strains. There is also usually more yellow on the breasts of the pullets, or brown in the case of the Partridge cross; but this also is not a sure test, as I knew of two splendid hens, bred from some of Mr. Boyle's best birds, which had very stained breasts, and yet bred chickens again of the first quality. The comb will, however, be always more or less faulty, being, although generally triple in character, much too high on the head of the cock, and trembling with every movement of the bird. Most, in fact, of the large, loose, trembling combs we often see arise, in my opinion, from a Cochin stain. The cock will also very often have perceptibly red feathers about the hocks, and the hen about her shoulders; and in these places a red colour is nearly conclusive, though, as already observed, it is by no means infallible when about the breast. Nearly all Cochin-crossed hens, however, acquire a great deal of red somewhere in their second moult, though they may as pullets have been good in colour.

Another sign of a Cochin stain is a frequent tendency to incubation. I would not insist on this in the case of a single bird, though I have never myself had a Brahma which showed any desire to sit until she had laid at least thirty eggs, and generally more; but when the propensity occurred generally in a yard I should regard it as conclusive of a cross with the Shanghae, though perhaps generations back.

It will be seen that scarcely any one sign is infallible in either case, and to determine the question of a suspected cross requires much judgment and careful comparison of different points. Other experienced breeders may see further signs, and if so, I shall feel glad to have them pointed out, for my own benefit and that of other readers.

It will be seen, also, that I am little likely to agree with "An Old Dorking Cock," who attributes Brahmas to a cross between Dorkings and Cochins! I have shown how characteristic is the slightest taint of either breed; and his opinion will never be shared by any one who has actually bred for three successive years either a Cochin or a Brahma. Into the vexed question of their real origin this is not the place to enter; though I may yet have a friendly nut to crack with him on the comparative merits of the fowl Miss Watts justly calls, "About the best we have ever had."—Nemo.

SALT FOR POULTRY.

In answer to a correspondent, you stated that salt was considered injurious to fowls. Can any of your readers give any reliable information on this matter? I have been in the habit of mixing large quantities of table salt in the food of my fowls, but whether it has done harm or good I cannot tell.

I believe the general impression is, that salt is actually necessary to animal life, so that I cannot understand how it can be injurious to poultry.—E. S.

[The work you quoted is no authority. It is quite certain that though salt is beneficial to many animals, it is not essential for the preservation of health in all. We shall be glad of a reply from any one who has given salt to fowls.—Eds.]

BREEDING GAME FOWLS.

(*Concluded from page* 201.)

When crossing colours, in breeding in the following cases, the hens will prevail more than the cock:—1st, When there are more than six hens to each cock. 2nd, When the hens are dark with dark legs, and the cock light. 3rd, When the hens are full grown and the cock not full grown. Also, in breeding from Game hens with a barndoor cock, the progeny will be "Gamer" than if breeding from a Game cock with barndoor hens. The fighting properties are, however, inherited more directly from the cock than from the hens in breeding Game fowls together, which made the best breeders for the pit in general more careful of their best brood cocks than of their brood hens. In all animals of both sexes, those taking most after their sires are considered to be both the strongest and the most spirited—as a rule.

Breeding from fowls not full grown is a great mistake, as even if they produce quicker birds, which some say, though contrary to my own experience, they at any rate produce weaker, and smaller, and softer birds in both flesh and bone.

In crossing light and dark colours together, it is well known in all animals that the darker colours must gradually prevail and eventually absorb the lighter colours, and that the only way to prevent or retard this is, to keep most of the males of the lighter colours, or to have all strong vigorous males of the lighter colours. Dark-coloured animals are generally the strongest, Dark Brown or Dark Grey birds more especially so. In changing brood cocks in crossing from Brown Red to Black-breasted Red; for instance, it will alter the tinge of colour in the eggs of the hens, the Brown Red cock inclining them to lay a white egg, while the red-eyed Black-breasted Red cock will make the eggs of a pinkish tinge, though not so much so with Brown Red hens. A yellow or daw-eyed brood cock will cause yellowish-tinged eggs in like manner. If the brood cock does not influence all qualities, he is never a first-rate bird. Some say the cock influences colour and the hen shape, others that all external qualities are from the cock, and all internal qualities from the hen. I am certain that good cocks influence all properties, more in all respects than the hens ever do.

The immense difference between spring-hatched chickens and summer-hatched chickens, even though from the same parents, is worthy of remark. Those hatched in the spring (the proper time), running the right height on the leg, light and hard in flesh, with the right amount of bone; while those hatched in June or July run low on the leg, heavy and soft in flesh, and too small and weak in bone, and, therefore, if such were matched to fight against birds bred at the right season, they would have to fight with much longer-reached and stronger and harder birds, though not at all heavier than themselves, and would, consequently, be easily beaten, even if equal in blood. I may here mention that I have had good broods in June and July, though not equal to the spring birds.

Breeders for the pit generally allow three hens to a "stag" in breeding, and five hens to a full-grown cock. Some, however, prefer only two hens to the full-grown cock, or even one favourite hen to the favourite cock, only one hen is not enough; but two good hens are sufficient for the best cock, and I am convinced that the best Game chickens are bred

from two first-rate hens put to a first-rate full-grown cock in a good grass run.

It should be recollected in breeding Game fowls that the relationship as to blood stands as follows—viz.:—

1st, Brown Reds, Dark Birchens, Dark Greys, and the dark or gipsy-faced Blacks are all closely allied in blood, and are all dark-combed or dark-faced birds, and all from one origin, that of the Brown Reds, which is their original colour.

2nd, That all the red-eyed breeds are closely related, all originating from red-eyed Black-breasted Reds, and red-eyed Gingers.

3rd, That all yellow or daw-eyed breeds and strains are closely allied in blood of whatever colour, they are all springing from the yellow-eyed Gingers originally.

The colours of the eyes are not sufficiently looked to by most breeders, who do not seem to be aware that this is the very best criterion of the difference in blood of all. No good cross can result from breeding different colours of eyes together, too much difference existing for the blood to amalgamate properly, as may be seen on trial for experiment.—NEWMARKET.

BRINDLEY'S INCUBATOR.

I HAVE no wish to enter into a controversy with Col. Stuart Wortley about the supposed merits of his new incubator or the supposed demerits of my own; but in justification of my previous remarks in the Journal, perhaps you will allow me space to quote from a letter which I have to-day received from St. John Coventry, Esq., to whom I supplied an incubator some six or seven weeks ago. I could adduce further letters, but this one shall suffice.—JOHN BRINDLEY.

"Mr. St. John Coventry is glad to say he finds the incubator work perfectly, only requiring a little attention, and less as one understands the working of the machine. The last few days have been a very trying time for incubators, the thermometer varying from 30° to 50°; and by a very little management of lamp, &c., he has kept his incubator at 100°, not varying during this changeable weather 2°.—*Wimborne, March 25th.*"

DARK BRAHMA POOTRAS.

As I was one of the earliest breeders of these excellent fowls, and one who in the early days of their recognition in our prize lists, exhibited constantly, and, as the records of your valuable paper will show, with pretty fair average success, I wish to make a few remarks upon the question of colour. I am aware that my views will be attacked, as they are diametrically opposed to those of "NEMO," "Y. B. A. Z.," and all of the writers on this subject; but I am quite sure that these are all wrong in advocating the dark breasts of pullets, and the black breasts and thighs of cocks; and how Mr. Lacy and his supporters can contend that brown is the proper ground colour, I am at a loss to conceive.

I forget the year of the Anerley Show, but I was a young and a very successful exhibitor at that place; I do not think I exhibited Brahmas, but one of the best breeders at that time complained of the decision of the Judge, and thought his Brahmas the best ever exhibited. Mr. Hewitt was the Judge, and he called myself and several others round him, showed us some feathers pulled from the breasts of the disappointed exhibitor's birds, laid them on a white sheet of paper, and said, "Why, they are almost as brown as a Cochin's! It is useless to show birds with any strain of brown in the ground colour, and I have, of course, passed them over." I mention this to show that in our early days we aimed at a beautiful silvery-grey hue, and in all my early pullets I am glad to say I still continue it. After the first moult, however, they gradually become browner; I, therefore, persist in saying, the breast of pullets should be a light silvery grey, thoroughly and delicately pencilled with black, and rising almost to white in the throat. If our breeders would aim at this, and not at obtaining dark-pencilled breasts, they would not be so apt to get brown patches on the wings of the cockerels. I also think it desirable to have a well-spangled breast on a jet black ground for the cock in preference to a full black breast.

I am confident that the brown shade has been imported into the Brahmas during the last few years by an attempt to cross with a Partridge Cochin. I, therefore, mean to adhere to my original strain, and I feel sure breeders will continue to come to me, as they do now, for my birds, as they find they are losing that silvery-white ground colour which all of us who were the original breeders so long struggled for. I am aware I have been sometimes beaten this season because of my strong prejudices as to colour, but I feel confident that in the end I shall prove to be right. I seldom trespass on your columns, but this question now assumes some importance, and now that I have had my say, I shall not trouble you on the subject again.—J. K. FOWLER, *Prebendal Farm, Aylesbury.*

HATCHING BY AN INCUBATOR.

A FRIEND of my mine last year had an incubator which proved quite unsuccessful, independently of its causing great loss of time and annoyance by its non-success. Probably he might have failed to carry out all the instructions, though I am fully aware he did his best to adhere to them. I should feel obliged if some of your numerous readers would give detailed accounts of incubators where their use has been attended with success, and answer the following questions:—

1, Will the dry heat from an incubator prove as beneficial as natural means?

2, Are the chickens when hatched by this artificial means as strong in constitution and as sound in feather as those hatched by natural means?

3, Do those birds hatched by incubators—viz., Hamburghs, Polands, and Game, whose chief merits depend upon correct colour of feather when adults, display the same feathering as when natural means have been employed?—TUDOR.

MELROSE POULTRY SHOW.

THIS Show, held in Melrose Corn Exchange on the 21st and 22nd inst., was most successful in every respect, there being nearly 250 entries, and the hall of the Exchange, was on both days crowded with visitors.

DORKINGS.—First, T. L. Jackson, Bush Ewes. Second, Lord Binning, Mellerstain, Kelso. Third, J. White, Warlaby, Northallerton, Yorkshire. Highly Commended, T. Raines, Bridgehaugh, Stirling. Commended, Countess de Flahault; Lord Binning.

SPANISH.—First, J. Thresh, Bradford, Yorkshire. Second, Master A. Redpath, Edinburgh. Highly Commended, W. Paterson, Langholm. Commended, D. Waugh, Melrose.

COCHIN-CHINA.—First, E. A. Aglionby, Esthwaite Lodge, Hawkshead. Second, W. R. Park, Abbotsmeadow. Highly Commended, E. A. Aglionby. Commended, Mrs. Dickens, Cornhill; Mrs. Waugh, Castlehill, Lochmaben.

BRAHMA POOTRAS.—First, D. Annan, Torr of Moonzie, Fife. Second, E. A. Aglionby. Highly Commended, Mrs. Waugh; C. Pease, Southend, Darlington.

GAME.—First, Lord Binning. Second, D. Gellatley, Meigle. Highly Commended, W. Riddell, Newton, St. Boswells; J. Brough, Carlisle; W. Tait, Heatherlie, Selkirk; Lord Binning; W. Easton, Canongate, Jedburgh; J. J. Wilson, Darlington; W. Mahon, Jedburgh. Commended, W. Easton.

HAMBURGHS (Pencilled).—First, H. Pickles, jun., Earby, near Skipton. Second, W. R. Park. Highly Commended, T. J. Harrison, Singleton Park, Kendal. Commended, P. T. Paterson, Langholm; T. J. Harrison; G. Walker, Selkirk; W. Smith, Ainderby Steeple, Northallerton; T. Musgrave, Longtown.

HAMBURGHS (Spangled).—First, H. Pickles, jun. Second, R. Dickson, Selkirk. Highly Commended, Messrs. S. & R. Ashton, Mottram, near Manchester. Commended, Mrs. Blacklock.

ANY OTHER VARIETY.—First and Second, Countess de Flahault (La Flèche, and Crève Cœur). Highly Commended, W. R. Park (Crève Cœur); J. Hastie Commended, W. R. Park (Silver Poland); Lord Binning (Scotch Grey).

BANTAMS (Any variety).—First, W. Mahon. Second, T. C. Harrison, Hull. Highly Commended, R. D. Johnstone; P. A. Renwick, Kelso; Messrs. S. and R. Ashton; W. Mahon; D. Broomfield, Kelso. Commended, W. Easton, Jedburgh; F. L. Roy; W. Scott, Jedburgh.

SWEEPSTAKE FOR BANTAM COCK (Any variety). — First, W. Brown, Selkirk (Black Red Game). Second, Countess de Flahault (Black Red Game). Highly Commended, T. Raines (Game); W. Scott, Castlegate, Jedburgh (Black Red Game).

DUCKS (Aylesbury).—First, A. Haggart, Leslie, Fife. Second, Lord Binning. Highly Commended, J. A. S. E. Fair, Gilliestongues, Jedburgh. Commended, T. Paterson, jun.

DUCKS (Any other variety).—First and Second, T. C. Harrison, Hull (Mandarin, and Carolina). Highly Commended, A. Thomson, Mainhill, (Muscovy).

SELLING CLASS.—First, J. M'Millan, Jedburgh (Manorkies). Second, T. R. Paterson, Langholm (Golden-pencilled). Highly Commended, J. A. S. E. Fair (Black Red Game); T. L. Jackson (Dorking); J. Musgrave (Silver-pencilled. Commended, J. Harvey (Duckwing Bantams); T. Musgrave (Golden-Hamburgh); F. L. Roy (Game Bantams); R. Burrow, Longtown, Cumberland (Golden-pencilled); J. Dickinson.

PIGEONS.

FANTAILS.—First, H. Yardley, Market Hall, Birmingham. Second, W. R. Park. Highly Commended, H. Yardley; W. R. Park; T. C. Taylor, Marton Lane, Middlesbro-on-Tees. Commended, J. M. Watson, Gattonside.

POUTERS.—First, H. Yardley. Second, R. Paterson, Melrose.

NUNS.—First and Second, R. Paterson. Commended, P. A. Renwick, Kelso; W. R Park.

JACOBINS.—First, R. Paterson. Second, J. Gray, jun., Melrose. Highly Commended, Countess de Flahault; R. Paterson; T. Moffat, Newtown; P. A. Renwick; J. Gray, jun.; R. More, Melrose; H. Yardley; T. Turn-

bull, Whitrigg; J. Shiel, jun., Darnick; T. C. Taylor; J. Campbell, Distillery, Langholm.

Turbits.—First, Miss Crosbie, Gattonside. Second, W. R. Park. Highly Commended, T. Turnbull. Commended, W. R. Park.

Owls.—First, J. Fielding, jun., Rochdale. Second, H. Yardley. Highly Commended, J. Fielding. Commended, Miss Crosbie.

Tumblers.—First and Second, P. A. Renwick. Highly Commended, R. Paterson; H. Yardley; R. Irving, Langholm.

Any other Variety.—First, H. Yardley. Second, J. Campbell. Highly Commended, R. Paterson; P. A. Renwick; J. J. Wilson.

Selling Class.—First, Messrs. S. & R. Ashton (Barbs). Second, H. Yardley. Highly Commended, R. Paterson (Fantails, and Dragons). Commended, R. Paterson (Red Barbs); W. R. Park (Fantails); Miss Crosbie (Turbits); Miss M. Scoon, Melrose (Turtle Doves); T. C. Taylor (Carriers). H. Yardley, Pigeon Medal. Lord Binning, Countess of Flahault, H. Pickles, jun., all equal for poultry medal.

CANARIES.

Buff Don.—*Cock.*—First, J. Kemp, Galashiels. Second, J. Trotter, Melrose. *Hen.*—First, J. Kemp. Second, W. Bogie, Melrose.

Buff Flecked.—*Cock.*—First, J. Kemp. Second, R. Laurie. Highly Commended, J. Fairbairn, Melrose. *Hen.*—Second, J. Kemp.

Cage Bird (Any breed).—First, W. Bogie (Yellow Don Cock). Second, R. Laurie.

Judges.—*Poultry* and *Pigeons:* Mr. Dixon, Bradford; *Canaries:* Mr. R. Ballantyne, Hawick.

LAPWINGS, OR GREEN PLOVERS.

As I know there are numbers of the readers of The Journal of Horticulture who feel quite as great an interest in the keeping of unusual pets as of poultry, I cannot refrain from bringing before their notice domesticated Lapwings, as being not only a most interesting, but also in walled gardens a most serviceable "hobby."

The difficulty of getting young unfeathered Lapwings to live is always a serious drawback, as by far the greater proportion of them die within a few days of being taken, the newly-caught adult birds are, on the contrary, exceedingly easy to keep, and very speedily become almost as tame and docile as though they had been reared by hand; in fact, I myself purchased a few from Mr. Harrison, of Spalding, only a few weeks ago, that are now so familiar as to come directly to be fed the moment they hear the voice of the person who usually attends to them.

That Plovers must be exceedingly beneficial when running in a walled garden is evident on the most cursory inspection, for though they do not appear to take any notice whatever of growing produce, no worm, snail, or beetle ever escapes them, and being thus constantly on the look out for these destructives, whilst the birds themselves are so light and graceful of carriage as to do but little damage to crops, they speedily become the useful favourites I have represented. They will eat sopped-bread, corn, and small scraps of uncooked meat with avidity, and I find even boiled broken potatoes appear to them but little less palatable. A good feature is, that not being able to perch, if properly pinioned or even cut-winged, their escape from walled premises is impossible, whilst to spectators they appear as if still enjoying unrestrained liberty. The beauty of their plumage is no slight additional recommendation.—Edward Hewitt, *Birmingham.*

FOUL BROOD.

When the apiary of my friend Mr. Woodbury suffered so seriously from the disastrous ravages of foul brood, my own apiary, situated not many hundred yards distant, enjoyed perfect immunity from the disease. This was, to me, the more surprising, as we had often interchanged bees and brood combs, and he had kindly supplied me with numerous Ligurian queens. I saw enough, however, of the malignant character of the disease which attacked and devastated the hives of Mr. Woodbury, to regard with extreme apprehension the possibility of its appearance in my own apiary.

Until last spring I considered I had good reason to rejoice that, so far, my apiary had been perfectly free from any occurrence of the malady; but at the end of March I discovered a very bad case of foul brood in one of my best and most valued stocks. A strong colony was blown over in one of the frequent gales with which we were favoured in the early part of 1866. The hive was reinstated in its proper position, but a violent attack by the other bees of the apiary was made on it, every particle of honey was quickly taken away, and the bees disappeared. I now found six of the combs almost filled with abortive brood, chiefly of the previous summer, presenting an unmistakeable case of foul brood. No other hive in my apiary has, since then, exhibited the slightest signs of the disease, notwithstanding that many stocks must have partaken of the spoils when the affected hive was robbed. It would seem, therefore, that foul brood is not always of the extremely virulent and contagious character of that which devastated Mr. Woodbury's apiary, and has been so often experienced by German and American bee-keepers. I have had accounts from two or three individuals, who also state that they have discovered exceedingly bad cases of foul brood, which, notwithstanding the bees of their other stocks have had unhindered access to the supplies contained within, has remained entirely confined to the hives first affected.

The only way in which I can account for my own hive being attacked by this disease, is that during extremely hot weather in the preceding summer, when the hive was teeming with an abundant population, it was removed a distance of three miles, which involved confinement of the bees for many hours with some amount of shaking and other disturbance. Early in June, 1865, the hive, which was filling a large super, was transported into the country, the bees having been shut in the evening previously. The cover was removed from the super—a very large one on the adjusting principle—a sheet of perforated zinc being substituted for it, the wide entrance beneath being also closed with the same material. I considered the ventilation would have been ample, but on arriving at their destination I perceived that the bees were greatly excited. Few, if any, deaths took place in consequence, and the bees appeared to work with tolerable briskness, but their labours resulted in less success than the majority of the stocks in the same garden.

On the occasion of a cursory examination in the early part of the spring the bees appeared rather numerous but somewhat inactive; at the time of the destruction of the hive I found on two or three combs little patches of healthy larvæ and eggs, surrounded on all sides by foul brood. I believe it to have been impossible for the hive to have thriven, and have reason to be thankful that what at the time appeared to be a most unlucky and untoward accident, was doubtless a most fortunate one in its results for me. As it was, this hive, from its peculiar construction, would have been unexamined, and left alone until the time of putting on the adjuster super, consequently the presence of foul brood would have been totally unsuspected, and perhaps as hotter weather prevailed, its effects might have become more virulent, and its spread among my other stocks more certain and general.

With the exception of the last few sentences the foregoing paper has been written, and has been kept lying by for the pages of this Journal, for many months previous to the appearance of the letter of "A Lanarkshire Bee-keeper" on January 8th, and of "A Renfrewshire Bee-keeper" on February 21st of this year, so that it will be seen that I have not in the slightest degree been influenced by the remarks of those observant, reliable, and valuable contributors to apiarian science. I had previously acquainted Mr. Woodbury with my conviction that foul brood might be occasioned, and in my case certainly was originated, from excessive internal heat and undue excitement consequent on the confinement and removal of the bees during a period of great heat and of great activity in working. The quantity of abortive brood was so great that the principal mortality could only have occurred during the height of the breeding season. The six combs affected contained sealed brood to their very edges, the small portions tenanted by healthy larvæ, and eggs having been apparently cleared out for the purpose. Prior to the final accident and subsequent robbery, there was a large quantity of sealed honey in the side combs and at the tops of the six affected ones, so that there could be no suspicion of starvation having had any influence on the condition of the colony.—S. Bevan Fox, *Exeter.*

HIVES QUEENLESS, AND QUEENS UNFERTILE.

The following may, perhaps, interest some of your apiarian readers.

On Wednesday, February 20th, taking advantage of a very fine warm day, I overhauled four of my hives to ascertain the condition of their respective queens. A, B, and C were supplied with royal cells from a pure Italian hive, which came to maturity on or about August 24th. These hives were examined several times in the autumn, but from the agility of the queens in A and B, and an entire absence of brood, I came to the conclusion that the continued unsettled weather had prevented the queens from taking a successful wedding trip; although the drones, which were very numerous in both hives, were

finally expelled late in the autumn. In C, having failed to discover a queen after several examinations, I believed that no queen was in existence. D contained a queen, reared in a unicomb hive, which had not laid a single egg during the autumn, though I knew she was impregnated. I ventured, therefore, to put her at the head of a strong colony from which the native hybrid queen had been previously removed.

All these hives were thoroughly ventilated at the top from the beginning of November till the 20th of February, and stand on single posts out in the garden.

A and B contained mature pigmy drones and sealed drone brood in worker cells, but no worker brood, proving that their queens were still virgins as anticipated. C, though strong in bees, contained no signs of brood, and although the bees seem tolerably contented, is, no doubt, queenless. D contained many young bees, and plenty of worker brood. Breeding must have been going on in these hives in spite of free ventilation during the month of January, probably during the very severe weather we then experienced. In January, 1865, I found brood coming forward in a ventilated hive in very severe weather.

The consumption of food has been very great during the present season, but all my stocks are remarkably dry and healthy.—J. E. B., *Wolverhampton.*

DISTANCE WITHIN WHICH DRONES INFLUENCE.

Whether the fear of "An Old Friend of the Black Bee" is ever destined to be realised, that in the Hanoverian rat style his old and valued favourites are doomed to disappear before the foreigner, or, on the contrary, with more probability, that ultimately the latter may become absorbed by the predominating black, it is certain that the keen apiculturist cannot but look back with sincere pleasure to the time of the arrival of his first Devon stock, or earlier tiny box, and if (as in my own case) he possessed the variety alone in his district, the delight it afforded him in his walks to single out, and the nicety with which he calculated the distance of flight of his own active little yellow jackets amongst the humming throng on the clover field, or never thought their bright orange hue more brilliant than when contrasted with the purple of the more distant heath, when vieing with their duskier sisters in rifling its precious sweets. Then, subsequently, on visiting neighbouring apiaries, the sharp look out for hybrids. My first discovery of such is fresh on my recollection. A fine autumn afternoon found me, after a few miles walk, in an old manse garden—a beautifully sequestered spot, a hollow surrounded with hills, adjoining the peaceful old churchyard and ruined church where, till within late years, the curious stranger was shown the juggs (the collar which encircled the neck of the culprit, and by which he was chained to the wall, a relic of the severer punishment of bygone days). The bee-master asked my opinion as to the probability of a small third swarm surviving the winter, hived in a very large straw skep, a more suitable one not being at hand. I picked up a dead bee (hybrid) from the landing board, remarking that that pilferer had come far from home, but on inverting the hive found quite a sprinkling of similarly banded bees amongst the few combs built on one side of their capacious dwelling, and I was convinced, although their owner was somewhat sceptical, that here was a clear case of hybridisation. He, however, agreed to give the little band some feeding, on my telling him this would probably prove the best stock he possessed. I had the satisfaction of his coming to tell me the following summer that my propheey had been verified, the large hive had been filled and to overflowing, yielding him two fine swarms, and, if I remember, the earliest he had.

Visiting an extensive cottage apiary at a still greater distance in the end of last season to purchase a few hives, I saw at a glance two were hybridised, and, without touching, selected those two first by chance; after a careful examination of the entire apiary it turned out that for population or store each of these were worth any three of the long row.

The greatest distance, however, of drone influence coming to my knowledge was illustrated by the visit of a most enthusiastic bee-keeper last summer, who was nonplussed by the appearance of orange-banded bees, such as he had never seen in two of his stocks, his curiosity being fairly excited, and after telling the phenomenon to his acquaintances, and making inquiry far and near, at last tracked out my apiary, and made his appearance with a few of his workers in a vial to show me, and returned home triumphant with a light second swarm of the "real McKays" on his head.

The distances respectively from my apiary to the localities referred to, as measured in a straight line on the ordnance survey map, are one and eleven-sixteenths, three and one-sixteenth, and four and five-sixteenths miles.—A Renfrewshire Bee-keeper.

OUR LETTER BOX.

Fowls for Producing Eggs (*J. S., Sandhurst*).—Andalusians will do in a confined space, and they are good layers. They are also good for the table, but have dark legs. Houdans would be good birds for one of the runs, as they are hardy and bear confinement well. You do not say whether your runs are confined, or whether the birds are at liberty. Neither Andalusians nor Houdans sit, therefore, the third breed should be sitters, either Cochins, Brahmas, or Dorkings.

Continuance of Male Influence (*A. G. O.*).—It is a disputed point. We think at least three weeks.

Bullock's Liver for Fowls (*H. H. H*)—We do not advise meat-feeding at all, especially when fowls are in confinement. Give them plenty of soda of grass with abundance of soil adhering to them, and throw their food among it. You may give refuse cooked meat chopped fine to your fowls, if you will.

Face of Spanish Fowls (*Idem*).—The best exhibitors of Spanish fowls always keep the hens in partial darkness for some days before exhibiting them.

Cough Affecting Brahma Pootras (*R. W. B.*).—We have not the slightest doubt that fine weather will be the best doctor, and that the hen will speedily and thoroughly recover. She has probably a little ulceration.

Points in White Dorkings (*Novice*).—With the exception of the colour, White Dorkings are judged like Grey ones. They must be large, heavy, square, and have white legs with five toes. The colour should be white, not straw. There is latitude as to the combs, but the double are most esteemed.

Barbeziene Fowl (*J. S.*).—We are sorry we are unable to give you the information you wish. We do not know the Barbeziene fowl.

Game Hens not Laying (*Subscriber*).—It is because your birds are two years old and upwards that they do not lay. Pullets lay because they attain the age when they must lay; but after they have become adults, they follow fixed seasons, subject only to such varieties of temperature as we have recently experienced. For instance: in a house where we have sixty hens and pullets, our eggs diminished half when the ground was covered with snow. This latter has of late been a daily or nightly occurrence. Nothing interferes so much as snow with the health and comfort of fowls, and when they are not in health they do not lay. We never recollect a season when eggs were so scarce in January and the early part of February, and broody hens so much in request in March. Early chickens will be rare, and the good lusty April and May birds will, we hope, have such a "good time" before them, that in December it will not be seen they came late into the world.

Brahma Pootra Feathers (*F. Powell*).—The feathers you sent are most decidedly Mr. Boyle's school of colour, the brown between the pencillings being not more than usually appears in the second moult, though some birds remain quite free. The other strain named usually has the pencilling itself dark brown instead of black, and is of a more dead colour. The feathers are very good, and approach in their dark colour those which used to be shown by Mr. Teebay. If the black pencilling covered the ground rather more thickly I should call them perfect.—Nemo.

Lapwings (*G.*).—They have the first joint of one wing amputated, which prevents their flying away.

Liability (*J. R. Beyton*).—As you are sure the birds were well when you put them into the hamper, the purchaser is liable for the subsequent loss. If the bird dies speedily, equity would suggest that you supply another at a reduced price.

Exceeding Duty (*M. P. Draper*).—Such questions are not within our province; but we will add that there is no doubt you were quite right.

Book about Canaries (*H. W. N.*).—Brent's "Canary, &c." You can have it free by post from our office if you enclose twenty postage stamps with your address.

Breeding in Supers.—In reply to the first question of Mr. J. H. Walker which appears in his communication under the above heading in your last issue, page 220, the price of "Pettitt's Collateral Hive" is 45*s.*, with gratings and dividers cut in the crown-board for four supers, or with gratings for two supers, 42*s.* A wood engraving of this hive is given in page 23 of Pettitt's catalogue, with explanation and prices. To the second question—for the straw hive with the round hole in the top, a circular adapting-board would answer, as represented in Pettitt's catalogue, page 36, on hive No. 19, with the gratings cut in the centre and shut off with a zinc divider. This adapting-board can be firmly fixed to the top of the hive with two or three long screws, and unless the queen is a very small one she seldom ventures through the gratings, and if the supers are well ventilated breeding will seldom take place in them.—Sudbury.

POULTRY MARKET.—March 27th.

We have a short supply, and prices are well maintained with a rise as compared with last week. The effect of the long and severe winter is plainly seen, and if there were a good trade, poultry would be very dear.

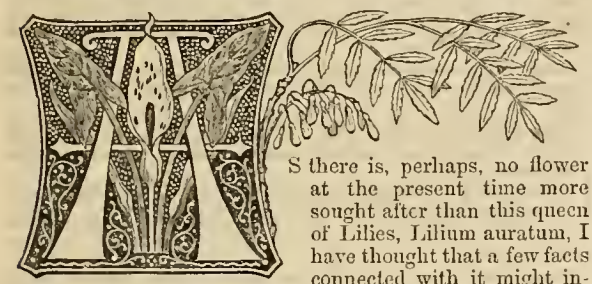
From observations taken near London during the last forty years, the average day temperature of the week is 56.9°; and its night temperature 36.0°. The greatest heat was 73°, on the 14th, 1852; and the lowest cold 20°, on the 15th, 1862. The greatest fall of rain was 0.56 inch.

LILIUM AURATUM AND ITS CULTURE.



As there is, perhaps, no flower at the present time more sought after than this queen of Lilies, Lilium auratum, I have thought that a few facts connected with it might interest those who are possessors of the bulbs, either as just imported from Japan, or else grown in the previous season by some nurseryman.

The history of the bulb affords a remarkable instance of commercial enterprise and the advantages of rapid communication which so characterise this age. It is now only a very few years ago—in 1862, that I was at Bagshot, at Mr. Standish's nursery, when the treasures that Mr. Fortune had collected in Japan were received there. There were shrubs, trees, herbaceous plants, and amongst them some bulbs of a Lily, which Mr. Fortune had described as twice as large as lancifolium, wondrously fragrant, and most gorgeous in its appearance. In the following July I was just entering the Royal Horticultural Society's garden, when I met some of our great growers coming out. "Is there anything remarkable?" was my question. "Yes. Mr. Veitch has there the grandest Lily that has ever been seen." And there, sure enough, diffusing its fragrance around, the admired of all admirers, the cynosure of all eyes, was Lilium auratum. It was shortly afterwards exhibited by Mr. Standish at the Crystal Palace, figured in botanical and floral books, and, in fact, became quite the rage. But then came the question, Who was to have it? Bulbs of it had been sold at fifteen guineas; and for years, we were told, the part of the multitude was to be that of the boys outside the eating shops—a look and a smell, but no taste. However, of course everybody who had any correspondent, or chance of a correspondent, in Japan, immediately wrote out to him, sending figures of the Lily, and requesting as many as possible to be sent home. By-and-by announcements of the arrival of the bulbs were made; but either the roguery or the blundering of the Japanese caused endless confusion. Heaps of other Lilies, which were not worth their weight in earth, were sent. One firm had 1500, not one of which came true; another 3000, in which the auratums were few and far between. After a while, however, things began to right themselves, and Mr. Stevens was able to announce, not merely supposed bulbs of Lilium auratum, but guaranteed ones; and now the bulb, which a few years ago could only be purchased for fifteen guineas, can be had for half-a-crown. Other facts have come to light since then. One is that there are many varieties of it, from pure white to those with a red stripe down the centre of each petal instead of the golden one from which Lilium auratum derives its name. Another was, that it was a great mistake to have described it, as was done, as one-flowered, inasmuch as bulbs with ten, twenty, and even forty flowers have been grown, thus increasing its attractiveness and value. An announcement has been made that upwards of 30,000 bulbs of it have been sold during the last two months at Stevens's auction-rooms, so that now the million may become possessors of this most lovely flower.

And now as to its cultivation. There have been many opinions expressed as to the most suitable soil for it, some advocating loam and peat; others loam, peat, and leaf mould; and others simply peat; while it is evident from some of the bulbs which have been imported that they have been grown, either naturally or artificially, in some strong clayey loam. Mr. Charles Turner, of Slough, who has been a most successful grower and exhibitor of it, uses peat and sand only; and in my small way I have followed his advice. But, as in everything else, there is a way how not to do it as well as to do it, and that way, I am sorry to say, I arrived at last year: let my experience, then, be a warning to others. The first mistake I made was in overpotting. Over-anxious, perhaps, to increase the size of my bulbs, I gave them far more room than they required. This would, probably, have been of but little importance had I not committed another mistake—viz., that of leaving the pots out exposed to the very heavy rains we had in August and September of last year. This so completely saturated the soil, that I am sorry to say I lost half of the few bulbs I had, and have learned a lesson which I hope others may profit by as well as myself. I do not think they ought to be put out of the cool greenhouse or pit, but treated as a greenhouse plant. It may be said, You place greenhouse plants out of doors. Yes, but it is when they are making their growth; whereas I put the Lilies out when they ought to have been going to rest, after their flowering was over.

Another fact that I have ascertained with regard to this Lily is, that when the seed is sown you need not be in the least discouraged if it do not come up the first year, or imagine that therefore a year is lost. Two years ago I sowed a pod of fine seed. It was sown in a pan, and placed in a propagating-house belonging to a neighbour. All last season there was not a sign of a plant coming up, yet when the seed was examined it was plump and fresh: and towards autumn I could see that very tiny bulbs were being formed underground, and there this spring they have come up as plentifully as Blackberries.

One remark more as to the newly imported bulbs. These come home, many of them at least, overland, and are plump and sound. Whether they are so, however, or more dried, the best plan is, I think, to pot them in small pots; and where there is convenience for so doing, to plunge them in the tan or sand of a propagating-house, giving them but little water, and encouraging them to throw out roots. When once they have done this all danger to the bulb is, I think, passed; and as soon as they have pushed out their roots vigorously they should be repotted in somewhat larger pots. What with importation, seedlings, and division of the roots, it cannot but be that ere long this noble flower will be as common as the lovely and still favourite Lilium lancifolium.—D, *Deal*.

CULTIVATION OF PEAS.

As an amateur gardener, having a town garden, I may as well state at once, that to obtain the largest quantity of produce in the smallest space of ground is to me a matter of very great importance, always provided that the quality be such as to give the quantity its full value.

My garden slopes off from a street on a hill-side towards the west, or rather north of west. On the north, south, and west I am blessed with a very pretty view of the country, and I am consequently well sheltered from the east.

The kitchen garden lies on the lower portion of the slope, and nominally occupies about three-quarters of an acre of ground; but what with steps properly so called—make-believe steps breaking the abruptness of the slope—and the room occupied by walks and some dear old Beech trees which have survived the summer suns and wintry storms of a century and half, my readers will readily calculate that the actual garden for cultivation is not very extensive. We (James and I as directors), make the most of it for choice crops by never attempting to grow Potatoes and Turnips, and thus we obtain a full supply of Peas, Beans, Sea-kale, Asparagus, Celery, Rhubarb, Cabbages, Cauliflowers, Greens, Onions, Carrots, &c., out of that portion which is allotted to cropping; but then James has two crops out of it every year.

The other portions of the kitchen garden are divided amongst my own peculiar favourites—a miniature fruit garden, well stocked with Apples and Pears, chiefly supplied to me by Mr. Rivers; a good supply of Strawberries and Gooseberries, beds of flowers for nosegays, and a bank left purposely in rude disorder for growing Ferns, &c., known as the "wild bit," and a pretty corner it is.

My flower garden lies on a flat piece of ground between my house and the Beech trees, and I do not like to rob that of its summer pride and beauty for nosegays, though I do like to supply flowers to my gardenless neighbours, so I lay claim to some beds for Pelargoniums, Asters, Phloxes, Zinnias, &c., in the kitchen garden, which looks all the brighter for the intrusion. In fact, it is as well to confess the truth at once, my garden is a curious, not to say heterogeneous mixture of the useful and the ornamental. Nevertheless, although it is a bad subject for description, it is a pleasant place to dwell in. My friends are wont to admire it, and so do I. Now, a museum may be a heterogeneous collection; but it may be very orderly for all that, and I feel fully justified in claiming the character of orderly for my garden; but this it owes to James, and not to me.

Well, but the Peas. Dear readers, I thought you would understand better what I may have to say about Peas or anything else, if you could in some degree localise yourselves with me: hence my preface. I grow Peas largely, considering the extent of my garden ground. Early sorts are always sown in short rows; but I care little for the small, shining, round, green shot, which are to my fancy the usual result. One dressing of each kind usually satisfies me; but this one taste I consider due to the gardener for his trouble and to the variety for a verdict. I wait for three favourite kinds—Fairbeard's Champion of England, Dent's Marrow, and the Gardener's Delight. All these rank with me as Peas, in contradistiuction to shot. Dent's Marrow is the sort I prefer, but as cooks and gardeners are against me, I must yield the palm to the Gardener's Delight.

In all gardens which I have had an opportunity of seeing, I have generally found the plan of narrow rows adopted for Peas. The seed-row is seldom more than 6 inches wide, oftener 4. My own Peas were formerly sown thus; but James has changed all that, and I have them now invariably planted wide—that is to say, from 12 to 14 inches throughout the row. A shallow trench is made of this width—namely, wide enough to admit the easy working of a 12-inch rake. A line is stretched so as to allow the edge on each side to be cut down clean, and the trench made nearly 2 inches deep, the earth being taken out with a flat square shovel. It is then raked down to make it perfectly level, but as no treading is allowed in the trench it is levelled and raked from the side.

It is now ready for the seed, so the garden line is stretched through the centre of the trench as a guide to the sower. This gives three well-defined lines—namely the two edges and the centre. Five rows of seed are sown. The three defined lines have the single seeds dropped exactly opposite each other. The two intermediate rows come in the angles, as represented in the accompanying diagram. Each seed is thus about 3 inches apart from every other seed. The seed is covered with soil in the usual way.

outer edge . . . . .
. . . . .
garden line . . . . .
. . . . .
outer edge . . . . .

When the young plants have grown about 2 inches high they are sticked with branchy young twigs about 2 feet high. These small sticks are dispersed amongst the young plants throughout the row, so as to catch their first tendrils and draw them into good upright growth. As soon as more support is found necessary, Pea-sticks, well branched and about 4 feet high, are stuck thickly on each side close to the Peas, but not now in the centre. These sticks, like the first short row, stand quite upright. My Peas, however, are vigorous growers, and rejoice in a rich garden soil, so they accomplish a journey of 8 or 9 feet skywards: consequently a third support is required, and this is supplied in the form of less branched but more substantial sticks, just such as are used for Kidney Beans. These are placed slanting, being stuck in about 6 inches beyond the rows at the bottom. The tops are brought to meet thus—Λ.

The object of the tall sticks is not only to enable the plants to climb higher, but as the sticks are fastened together at intervals with tarred cord, to take which a tall stick is every now and then laid across, in a sloping direction, the whole mass is held together, and is thus enabled to stand the brunt of almost any storm which may arise. I have very often had the satisfaction of seeing my Peas unmoved and uninjured, when neighbouring gardeners in the district have been complaining that their narrow and slightly-sticked rows of Peas have been nearly demolished by the "nor'-westers," which are our prevailing winds.

This mode of sticking gives so much air and room to the inside portion of the crop, that no ground is lost, and the whole rows are usually well covered with a mass of fine pods throughout the "length and breadth of the land."

I have stated that my Peas grow on rich land. James is a strong advocate of deep trenching, change of manures, change of crop, and double cropping. He grows a large quantity of Celery; this necessitates deep work and large supplies of manure. By changing the Celery ground every year, the whole of the cropped ground is kept well worked. The Peas always succeed the Celery, consequently have the first benefit.

My rows of Peas are about 52 feet long, and are placed 5 feet apart to allow of the wide sticking. Each row takes a quart of seed. No crops are planted between.

Now, the first impression on the mind of the reader will probably be, that more ground is occupied for a given quantity of Peas by this mode of culture, than by the ordinary narrow-row plan; but my experience as a housekeeper, as well as gardener, tells me that I obtain nearly double the amount of produce from my ground by the wide plan! I can most unhesitatingly say one-third more, and my own conviction is that double is more nearly correct.

The next point for consideration will perhaps be, whether sticking so many times does not cause much additional trouble; but, which is better, to stick three miserable rows once, or one valuable row three times? If the narrow rows are sticked twice, as they sometimes are, then three times two are six, exactly double the trouble for the narrow rows! Of course, some people may find a difficulty in procuring Pea-sticks of from 10 to 12 feet long; but then they cannot grow the Gardener's Delight or Dent's Marrow in perfection. I pity them.—C. P.

BLUE PRIMULA.

Do you happen to know the origin of the blue Primrose, or rather perhaps Polyanthus, now quite banished from modern gardens? Both a neighbour and myself have been trying in vain to obtain a pod of seed, but neither in the open border nor under glass are we successful. This seems to point to a hybrid origin, but I know nothing but a blue self Auricula that could have turned the yellow of a Primrose into blue.

Last year I removed to my flower-borders the best out of a lot of Polyanthus seedlings. Strange to say some plants which were thrum-eyed last year, are, as regards the majority of their flowers, pin-eyed this.—G. S.

[The smallness of the pips and grey blue of the corolla suggest that Primula denticulata may have some title to its parentage. P. venusta or others might impart such a colour. —Eds.]

Iresine Herbstii.—Not having seen any reply respecting the flowering of Iresine Herbstii in England, I enclose a small

spike from a plant in flower here. As a plant for table decoration it is a valuable addition, and for bedding purposes far superior to either Perilla or Coleus Verschaffelti, it having remained here uninjured by frost, when both the others were killed.—Samuel Watts, *Gardener, Abeylasney, Carmarthen.*

HEATING AND UTILISING A HOUSE-OF-ALL-WORK.

My greenhouse is a lean-to, 30 feet by 14, and the aspect S.S.W.; the back wall, lined with brick, is 9 feet 6 inches high, the front wall 6 feet high; the roof, rather flat, is fixed, and glazed with 21-oz. glass in squares 20 inches by 16. The front lights are all made to open, and there are wood shutters as ventilators in the back wall, three on a level with the front lights, and two others just under the top of the wall-plate, each measuring 2 feet 6 inches by 9 inches. There is a door 3 feet wide exactly in the middle of each end. The east end consists of 3 feet of stone, with glass above; the west end is a 9-inch brick wall, with 16 inches deep of glass at top. I have hitherto used a Walker's iron stove to exclude frost, placed exactly in the centre of the whole length against the back wall. What I aim at is, to grow Vines with little or no forcing; to preserve bedding plants through the winter; to propagate cuttings, &c.; and to use, if practicable, the propagating-bed or pit for Cucumbers, possibly Melons, when spring propagation is over. Is the combination of these objects practicable?

The present internal arrangement is as follows:—The whole floor is laid with common flooring-tiles 9 inches square; against the back wall is an earth-bed 2 feet 6 inches wide from end to end, (except a space of 2 feet 6 inches where the present stove stands), kept up by an 18-inch brick wall. Three rows of wood pegs in the wall support three tiers of shelves. The front is thus arranged:—A series of brick piers 9 inches square, is built at a distance of 3 feet 3 inches, outside measure, from the front wall, all being open below, which piers support flags about 2½ inches thick running the whole length. From the upper surface of the flags, which is 2 feet 9 inches above the floor, is a further height of 1 foot to the level of the wall-plate, with 20 inches of glass above, making the whole height from the floor to the wall-plate 3 feet 9 inches. Into the brick piers, both front and back, I have built some bars of one-eighth-inch sheet iron, 15 inches long by 1½ wide, so as to project 3 inches on either side of the piers. Upon these, from front to back, I lay cross stays of wood, of course 3 feet 3 inches long, being the width of the flags above, which support a most convenient row of shelves, moveable at pleasure. Under the shelves, on the floor, I store flower-pots, coke, and watering-cans, and upon the shelves, boxes, tools, &c. I should be obliged by some suggestions as to heating.—G. P. C.

[We should have preferred your greenhouse vinery 14 feet wide, and 6 feet high in front, to have been more than 9½ feet high at back, as the flatness of the roof will render it chiefly useful for summer crops, though also suitable for keeping plants in winter. We think that you will have abundance of ventilation, and no doubt these openings in the back wall, on a level with the front lights, will be useful, but we would have preferred three instead of two ventilators, just under the apex at the top of the wall, as that will be the hottest place. However, it would be a pity to alter them now after the wall is finished, but if you find these two ventilators do not give you quite enough of air in very hot weather, you can take out a square of glass just under the apex at each end, leave them out in summer, and replace them in the end of autumn. You will hardly want this if you grow Cucumbers and Melons in summer, and in that case it will not be advisable to open much the lower ventilators in the back wall.

Now, as to your proposed combinations:—1. You may grow Grapes with little or no forcing; but with little heat we would have preferred Muscat Hamburgh, Royal Muscadine, and Buckland Sweetwater, to be joined to the four Hamburghs, instead of Muscat of Alexandria, and Grizzly Frontignan. To ripen the latter well will require more heat than would ripen the Hamburghs.

2. The house will do admirably for your bedding plants.

3. To propagate by cuttings in spring, and at other times. This would be best done in winter and early spring, if the Vines are in the house, and you have no desire to start them early so as to necessitate forcing, by having a part of the house heated, and covered with glass, &c, whilst the rest of the house may be kept cool, with plenty of air, to suit bedding plants.

4. Provided such heat can be given, Cucumbers and Melons can be grown in the same house at the same time with the Vines, where the Vines do not shade. Before the Vines shade they might be grown in the centre of the house, in the eight-feet space left, in pots. Even after the Vines were pretty well established, you might have a narrow frame or box nearly 4 feet in width set in the middle of the house, with paths 2 feet wide, back and front, and if you threw bottom heat into that, by hot water or otherwise, and covered the glass at night to keep in the heat, you could have early Cucumbers growing there by the time the Vines were budding, and then when the Vines were in full leaf, the rays of light that would pass would serve pretty well for the Cucumbers in early summer, after the glass of the frames was removed. There is often loss, however, in attempting too much, and, therefore, though we would not object to a few pots of Cucumbers and Melons, we would advise making your house chiefly subservient to Vines, bedding plants, and other greenhouse plants, and having a propagating-bed heated separately.

We consider that the Walker's iron stove you now possess is quite sufficient for ripening late Grapes and keeping bedding plants over the winter, but you cannot well use it for securing heat for propagating-purposes. As you are acquainted with the brick Arnott's stove and the small boiler used by Mr. Rivers, then you cannot do better than use one of them; and as you have gone to the expense of the stone platform in front, and wish that to be the base of your propagating-bed, we would advise the stove to stand in front of the house, and there it must be sunk so much that the top of the small boiler is not higher—better a few inches lower—than the level of your stone platform. You must not have the boiler higher than the pipes or tank will be, but as much below as possible.

You have shown the proposed stove placed near the front of the house with a short horizontal pipe, as we always recommend for such stoves, and then an upright pipe through a square of plate iron instead of glass, which is quite correct, and better than the other proposed plan of taking the smoke-pipe across the house under the glass, and then out near the back of the house. The additional dry heat thus gained would be anything but real profit; and if the furnace and ash-pit doors are close, the draught can be so regulated that there will be little loss of heat. But for the pleasure of doing all the stove work inside, such a stove could be placed close to the front wall, and the openings for feeding and ashes might be outside the house.

There need be no difficulty as to soot collecting in the short horizontal pipe close to the stove, as, if coke or clean cinders are used, little will collect so near the fire. A brush may be passed down the pipe now and then, and the soot may be pulled out easily from the horizontal part when the feeding-door is nearly opposite the smoke-pipe. In all such stoves it is desirable to have the feeding-door a foot or 18 inches above the grate-bars, and then a small poker must be used, and the hand put in on lighting. Of course this gives a little trouble. In a recent volume there is a plan of fire-bars which fall down into the ash-pit, and thus allow all to be easily cleaned out, and which are as easily put in their place again. All stoves inside of a house require a little nicety in management, and as economy in fuel is a great object, the high feeding-door we consider in that light to be an advantage; otherwise there is no objection whatever to what you propose—namely, a high feeding-door, and a door opposite, just above the fire-bars, to permit of easily cleaning out and easily lighting—except the expense of the additional door, and the difficulty of so keeping it close as to prevent more draught than would be required; for after being fairly set going, the economy of such stoves consists in imparting a genial constant heat with the smallest consumption of fuel.

It is never desirable to make the water boil in the pipes. The fire must be replenished according to the heat wanted. When the heat is strong from a keen draught, the coke or fuel will become mostly incandescent, and when the draught of air is lessened the fuel will remain so a long time before being consumed. How the heat rises from the coke to the boiler that forms the top of the stove, would just lead us to tell how the heat rises from the grate in a kitchen to the large pot or kettle that is placed over it.

There need be no fear of deficient draught if your horizontal pipe is short, from 1 to 2 feet in length, and then turns upright into the open air; but if you have the least doubt satisfy yourself by all means, by trying the stove first without the boiler. It would be well to have a cowl over the top of your smoke-pipe outside, to prevent the rain finding its way into

it, for that will cause soot to accumulate more than anything, and it is difficult to clear it out of iron pipes, and if the material is sheet iron the pipe will soon wear out. A bent iron pipe placed in such a stove would not suit you so well as a small boiler. In larger furnaces it would answer better than in a stove, where the fireplace is more limited in size. There is, however, little force in the objection to such a bent pipe being soon worn out. A strong cast-metal pipe, always full of water, may be depended on, if it have fair play, to last as long as any boiler. These small boilers, as used by Mr. Rivers, placed on the top of such an Arnott's stove as you propose cost little, and in your case we think would be decidedly preferable.

As to using pipes, a gutter, or a tank, over the flag-stone platform—which platform we presume is water-tight, or you would not have the dry shelves and storage-room beneath it—the subject of pipes *versus* tanks has so often been discussed by ourselves and others that there is little to be added, as we consider each system best just as it can be most easily and economically applied. One error we would just notice. Many speak of the heat from hot-water pipes being so much more moist than that from a flue, or a stove; and, again, of the heat from a tank being so much more moist than that from pipes. Now, all are equally dry if the pipes are close and sound, and the tank closely covered. If the covering of the tank is loose and open there may at times be too much escape of moisture. Well, you want to know how to proceed in either case. Then, first, as to pipes. You may have four-inch pipes if you wish, but two three-inch pipes would do for such a place. These would cost respectively from about 2*s*. 3*d*. to 2*s*. 9*d*. a yard, and more for bends and circular junctions. Presuming that your flag-stone is water tight and abuts against the front wall of the house; after placing the pipes along the stones, and having a small cistern at the end, alike to supply the pipes and boiler, and permit of the expansion of the water, you may either cover the pipes with slate, &c. an inch or two above them, to receive the pots, and plunging material if deemed necessary, or you may, as we would prefer, place open rubble round the pipes and for an inch or so over them, and then nearly an inch of fine washed gravel, to be followed by sand, &c., for the pots of cuttings. In the latter case we would have at every yard or so a small earthenware drain-pipe set upright, its upper end open and furnished with a wooden plug, its lower end also open and standing a couple of inches above and clear of the flags. From these drain-pipes one can let dry heat into the atmosphere of the propagating-place by taking out the plugs, or one can have moist heat by pouring some water down through the drain-pipes. In either of these cases you will have to make your stone platform the base of your propagating-bed.

To make a tank, we would proceed thus—Make sure of all joints in your flag-stone platform with white lead or cement, also where the flags join the front wall cement that wall to the height of at least 6 inches, if 9 all the better. As you proceed lay a brick edgewise in cement on the flags, and close to the front wall, that will form the front of your tank, then on the inside edge of your platform lay two bricks on bed in cement, which will form the back as it were of your tank. In the middle of the space left, run a brick on edge lengthwise, leaving an open space at the farther end, the one side to receive the flow-pipe from the boiler, the other to communicate with the return-pipe. Then cover all the sides and tops of these bricks, and the exposed parts of the flags, with a layer of cement, and when fairly set it is ready for the water. You may then cover over with thick slate laid in cement, common house slates loose, iron plate, &c. The front you can raise by brick on edge, or as giving rather more room, by a board. We think that if you can depend on your flags the tank would be the cheaper in your case. We may add, though it is chiefly a builder's question, that in forming such a tank, the bricks should be soaked before using them. The front wall and flags should be well moistened before applying the coating of cement, and if the flags are smooth on the surface, they should be made a little rough with the chisel before applying the cement. From 3 to 4 inches in depth of water will be ample. It will be as well to have some openings to let the heat up when wanted, instead of being confined below the propagating-pots.]

EARLY PEAS.

We had hoped our last letter in The Journal of Horticulture would have sufficiently explained the irregularity of character so untruly attributed to our First Crop Pea. Your correspondent in the issue of March 28th has evidently either fallen into the same error that "Ronnoc" laboured under —*i.e.*, confusing the old Carter's Early with our recent introduction, Carter's First Crop Pea—or, as we also suggested in our former letters, he has been the victim of a spurious substitution.

We are gratified to find our statement of its true merits confirmed in the Journal of April 4th, and we are convinced if more evidence of its sterling quality as the best "First Early Pea" were wanting, many hundreds of our customers who have procured the true stock from us, and have grown it more than one season, will be glad to give an impartial report of its real merits.—James Carter & Co.

THE OÏDIUM, OR VINE MILDEW.

Having found the following to be a complete cure for the above disease in Vines, I think it right to give it publicity, particularly as the season is now advancing for its use:—1 lb. of flowers of sulphur, 1 lb. of slaked lime, 1 gallon of rain water; to be mixed well together, and when boiled twenty minutes, to be taken off and strained; then to be added to the liquid 1 gallon more water, and boiled twenty minutes longer; next let the liquid cool (it will be of a fine amber colour), and put it into a large jar, and cork.

When to be used, take 1 pint of the above and throw it into 16 gallons of rain water, with which syringe your Vines, and it will not injure the fruit or leaves. If the Vines are under glass, syringe with cold water four days after its use.

I grow here a large number of Vines against and on walls for champagne and otherwise, and for the last four years have found that a single syringing with the above over my Vines on walls soon after blossoming, and when the fruit is about the size of very small shot, acts as a complete preventive to the disease showing itself in any shape whatever, although it is in its very worst form amongst my neighbours' Vines within a few hundred yards of me.

So effectual has the application proved with me that last year I sent my gardener to syringe several of my neighbour's out-of-door Vines, and in every case with the most decided success, even where the disease had made considerable progress. The mixture is on no account to be used during the blossoming of the Vines.

I do not see why it should not act as a preventive against other blights, and I intend this year to try it on other fruit trees, not waiting until the blight actually makes its appearance. I also intend to mark out about a land yard of my late Potato-ground, which my gardener shall syringe with the above twice a-week, commencing from about the first day of July next, and should there be any beneficial result I shall gladly inform you in due course.—W. A. B.

SOWING AND CULTURE OF CYCLAMENS.

Who does not love and admire Cyclamens? and they deserve to be admired, not only for their beauty, but because they are as easy to grow from seed as the commonest of annuals.

Having a few old plants in good bloom in March, and wishing to increase my stock, I placed them on a shelf near the glass in an airy greenhouse, keeping them dry rather than wet, and by August I had plenty of pods full of good seeds, ripening at different times. I visited the plants every afternoon, taking care not to gather the pods before each had partially burst, and they were then carefully packed and put away until the time of sowing—an operation which I perform according to the following directions. Early in March prepare six-inch pots by three-parts filling them with drainage, over this place a good layer of moss, and above the moss half an inch of loam, leaf mould, and silver sand passed through a sieve, using the roughest for the bottom. Make the surface firm, place the seeds, which should previously be soaked for twenty-four hours in milk-warm water, about a quarter of an inch from each other, and cover them very lightly with silver sand. Water gently through a very fine rose, always using warm water, or that from which the chill has been taken off, place a piece of slate or glass over the pots, and set them in a warm, close Cucumber or cutting-frame. In a month the seeds will vegetate, and when this takes place the seedlings must not be allowed to become dry.

When the seedlings are large enough to handle pot them in small thumb pots in turfy loam, chopped moss, and a little

silver sand, using plenty of drainage; return them to the frame for a week or two, keeping them near the glass, and watering them very carefully. At the end of that time they will want more air, and a little shading will be necessary in very bright days. The plants must not be placed out of doors, but should be encouraged in the greenhouse, and when they have filled the thumb pot with roots shift into 2½-inch pots, using the same compost as before. By the following March there will be enough of them in bloom to amply reward the grower for his trouble. Dozens of my seedlings sown last March were beautifully in bloom in ten months after sowing, and have been so ever since. Many of the corms or bulbs are as large as a two-shilling-piece. The varieties are persicum rubrum and those of the ceum and Atkinsii race.—H. C., *Hendre Gardens, Monmouth.*

THE GARSTON VINEYARD.

(*Continued from page* 64.)

After passing through the span-roofed houses numbered 3, 4, 5, and 6 we turn to the left, cross an open space on the north side of the dwelling-house, and enter the early vinery. This is principally planted with Black Hamburgh Vines; but there are one or two Trentham Black Vines, from which Mr. Meredith has cut magnificent bunches. Some of these were shown at the Regent's Park in July, 1865. At the same show Mr. Meredith exhibited the heaviest bunch of Black Hamburgh on record. This magnificent bunch, which weighed 9 lbs. 8 ozs., was produced on the point of a shoot, and took the form of an umbrella. I had the pleasure of seeing it a short time before it was cut; it was very symmetrical, the berries as black as sloes, and so even that they might almost have been cast in a mould. I may mention that several other bunches were grown on the same Vine, which was by no means a strong one.

The early vinery is 65 feet long by 23 wide, and has a span roof. There are six rows of four-inch pipes, three rows on each side of the walk in the centre of the house. There is also a large flue below the path. The ends of the house are east and west, so that one-half of the Vines are partly shaded by the others, yet those on the north side are as good as those on the south. The walk through the centre is about 5 feet wide; this leaves a border on each side 9 feet wide. The borders inside the house are well elevated above the ground level, and are about 4 feet 6 inches deep. There are also on the north and south sides outside borders, which are likewise about 4 feet 6 inches deep near the front of the house, but taper off towards the outside next the walk, where they are about 2 feet 6 inches above the general ground level. They are about 3 feet deep at the sides, so that below the ground level there is not more than 6 inches of good soil for the Vines to grow in.

I shall shortly give a section of the Vine-borders and vineries at Huntroyde, also a general reply to the disbelievers in the system of Vine-border making which I recommend. The borders I have made are not for the purpose of growing show Grapes alone; they are formed to last for many years, and to avoid the necessity of destroying the Vines just when these ought to be at their best. I ask "G. H.," Which is the less expensive mode of making a Vine-border—to make it thoroughly in the first instance, supposing it to cost £60 or £100 according to size, and with a view of its lasting in good condition sixty or a hundred years, or to make ten or twenty borders during that time, involving a cost for each border of from £15 to £30, and a loss of one year's crop of fruit every time the border is made, besides the disadvantages of having the place upset by these alterations?

The structure just described being the early house, during the first months of spring spare lights are placed over the outside borders. The house rests on pillars, and there is no glass at the sides. There are about sixty Vines, from which have been cut the Grapes exhibited at the early shows, winning so many first prizes during the last six years.

Retracing our steps across the open space at the back of the dwelling-house we enter another house facing that which we have just left. It is of the same dimensions, and constructed on exactly the same principle as the early Hamburgh-house, having borders outside as well. It is planted with Muscat of Alexandria and White Tokay, and when I saw it the Vines on each side of the span were covered from the soil to the ridge of the roof with bunches of beautiful amber-coloured berries very even in size. The bunches were most symmetrical, and would average about 2½ lbs. in weight, and in number seven on each Vine. Provision is made for heating the border if necessary. The soil in this and the early Hamburgh-house comes close up to the hot-water pipes, of which there are six rows. The Vines in each of the above houses were planted in a growing state in July, 1857; and although Mr. Meredith has cut such wonderful crops from them, he expects to obtain still greater results —indeed the appearance of the Vines would lead any one to the same conclusion. Every year they rapidly increase in size and productiveness. I did not prick over either the outside or inside borders in search of roots, but any Grape-grower could tell from the Vines that the borders were filled with fine healthy roots. "G. H." may take my word that roots are to be found in any quantity both outside and in; if there is any difference in their healthiness those in the outside border will perhaps be the best.

Leaving the early vinery we pass to the west side of the vineyard. Here there are several lean-to houses for the growth of Peaches and Nectarines, and in each the trees are in a very flourishing condition and give promise of good crops; but it struck me in passing through that they did not receive so much care and attention as the Vines. In front of this range is a span-roofed pit used for growing Tomatoes, &c. Retracing our steps to the early vinery and turning northwards, we pass between several ranges of Pine-stoves and convenient span-roofed houses for the growth of young Vines, Cucumbers, and Melons, situated on each side of the passage leading to the dwelling-house. There are seven of these forcing-pits. They are about 80 feet long by 12 wide, and are very efficiently heated with four-inch piping.

I now come to Mr. Meredith's splendid house of mixed Vines. On entering it, the sight of the enormous bunches calls to mind the wonderful Grapes mentioned in the thirteenth chapter of the Book of Numbers; by the brook Eschol, wonderful Grapes were grown without the aid of man. There is no doubt that the land by the brook Eschol was exceeding fertile; there is also little doubt but that the Vines extended themselves from tree to tree, and that their roots were freely watered by the brook. This, then, should teach us a useful lesson, and one that I have before particularly tried to impress on the memory of those who advocate the once-a-month system of watering the Vine; and the fact of the Vines producing such wonderful Grapes in their wild state, would lead one to believe that the extending system of Vine-growing so much written about lately is one that may be safely tried, and there can be little doubt but that it would succeed. If, however, this system were adopted to any extent, a single house would be required for each variety of Grape; double or treble the number of houses for the growthof Vines would, therefore, be necessary.

Mr. Meredith has shown the world what he can do by keeping the Vine within a certain limit, let him now show us what he can effect with the extending system. He could do this justice in a house of similar dimensions to that which I described in these pages some months ago. He might make a section of a border in the centre of such a house, there plant one Vine under the north side, and another under the south, and train the Vines right and left, adding to the border as the roots extended. Each set of branches would have just 51 feet to travel from the main stem, and about 25 feet of roof in width. I have little doubt that, under proper treatment, two Vines would cover the whole roof of this large structure in six years from the time of planting. Would not this be worth trying? If it were thought desirable a ribbon of Grapes might be obtained in such a house by grafting different kinds on the principal Vine. Thus a yard or more in width of white Grapes might run the whole length of the roof, then a yard of black Grapes, and so on. What a magnificent sight this would be. Large numbers of pot Vines might still be grown in the same house, and many other subjects that would help to pay for nursing the Vines till such time as they had arrived at a size to produce Grapes by the half ton. Good crops of Grapes might be taken from the Vines after the second year.

Returning to the house which I had begun to describe, and which called to mind the wonderful Grapes found by the brook of Eschol; although it is of much smaller dimensions than that to which I have been referring above, it is of no mean size, being 128 feet by 17. The roof is rather flat, at least, that part of it facing the south, and there is a short north light about 5 feet wide, and under this the walk. At present there is no outside border, but Mr. Meredith intends to make one very soon; the border inside is about 12 feet wide, and 5 feet 6 inches deep. Let "Vitis," or any of the advocates of shallow borders but see this wonderful house of Grapes, and I

think their opinions will be changed on the instant. The Vines have been planted about six years, and there are five rows of four-inch pipes on the top of the border. To make a border outside 12 feet wide, and 128 feet long, will cost Mr. Meredith, I should think, not less than £130, as he will be obliged to buy all the soil, bones, &c.; but, of course, he will not make the whole width at once. He will, probably, make the border in three four-feet sections, but he will be obliged to make it, and that soon, or spoil his magnificent Vines. I entered this house at the east end, and the first Vine that met my view was a Lady Downe's bearing twenty-two bunches of beautiful Grapes as black as sloes, the bunches averaging 1½ lb. each, and several of them would weigh not less than 2½ lbs. to 3 lbs. What does "G. H." say to the show system of Vine-border making after this?

I find I have omitted to mention that there is a front light to this house which is opened by means of a spindle and lever; the light is 18 inches wide. At the time of my visit there were hanging close to the front lights many bunches of Grapes which reached from the top of the lights to the soil. Mr. Meredith's reason for planting a large number of different kinds of Grapes in this house is, that gentlemen about to plant may select those most suitable to their taste and requirements.

After passing by the Lady Downe's, the next Vine that Mr. Meredith called my attention to was a Barbarossa, this had three bunches, the united weight of which would not be less than 30 lbs. The next Vine, a Lady Downe's, had sixteen fine bunches, and then there was a Barbarossa with three bunches, weighing about 20 lbs. The next that attracted my attention was Child of Hale, with four bunches, the united weight of which would be about 36 lbs.; one of the bunches I should think would weigh 12 lbs.; this measured 16 inches across the shoulders, and 17 inches in length. When standing under it it appeared almost large enough to shelter one from a shower of rain. This bunch was near the top of the Vine, and hung just over the walk, so that I had a good chance of thoroughly examining it.—J. Wills.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

Dr. Masters, in his second lecture on Plant Architecture on Saturday last, after recapitulating some of the more important heads of his previous discourse, took for his subject the Root, that being the first part which is protruded when the seed begins to germinate, and constituting the basement of the vegetable edifice. After describing the usual manner in which roots are formed, he remarked that adventitious roots, for such is the distinction usually made, may be emitted from almost any part of a plant, and occasionally from the most extraordinary places, as from the fruit of the Cucumber, and mentioned that in France Cacti are occasionally propagated from cuttings of the fruit. Some of the principal modifications of the root were then pointed out, as well as the immediate causes of these. One important use of the root was to fix the plant in the ground, and Dr. Masters remarked any one who had visited Cliveden must have been delighted with the ancient Yew trees growing on a chalk cliff overhanging the river. There the rugged roots not only help the trees themselves, but perform an important office by keeping the chalk from slipping. One reason for roots generally going downwards was that they thus more effectually secure the plant from the wind; but they did not always assume a downward direction, the Mistletoe and Cattleya citrina being given as instances, in fact in the latter the roots actually go upwards. Another most important office of the roots was to serve as a feeding process, and in connection with the fact that they lengthen at their points only, and their consequent power of insinuating themselves into small crevices, the lecturer referred to a plan proposed by an Irish gentleman at the Botanical Congress in May last, of placing drain pipes on stones instead of on soil, with the view of keeping the roots out of the pipes, by tempting them with moisture which would escape from the latter among the stones. The importance of the feeding roots being near the surface was then insisted on, and Dr. Masters observed that he had lately been to Sawbridgeworth, where Mr. Rivers had shown him trees growing most luxuriantly, with their roots rioting near the surface in porous soil charged with manure. Some years ago, when his orchard-house trees in pots were placed on a loose border and little or no surface-dressing was applied, the roots constantly formed spiral coils in the pots, passing out at the bottom and then throwing out fibres; but now that the pots stand on a hard border, and rich surface-dressings are given, the roots no longer become corkscrewed, but form a mass of fibres in the pots. Roots also acted as storehouses of food, their cells being filled with starch or sugar, and often a large amount of water. Here, the lecturer said, he might mention a curious circumstance which had only come to his notice last week. Mr. Barron, the Superintendent at Chiswick, had sent up a number of cuttings to the lecture, and on examining these under the microscope Dr. Masters said he found the callus, or mass of cells formed by the cutting in striking, contained starch, which, no doubt, would become converted into sugar. Hence he concluded that the callus acted as a storehouse of nourishment for the future plant in the same way as the seed and some kinds of roots. After the importance of fibrous roots in transplanting and in fruit-tree culture had been referred to, the Stem was announced as the subject of the next lecture.

ENTOMOLOGICAL SOCIETY'S MEETING.

The first meeting of this Society for the month of March was held on the 4th, the chair being taken by Mr. F. Smith, Vice-President.

A small collection of Beetles and Lepidoptera collected in Madagascar was presented by M. François Pollen, of Leyden. Mr. F. Bond exhibited some specimens of a small species of Ichneumon, of which as many as 447 individuals had emerged in the larva state from the body of a caterpillar of Dasypolia Templi. This caterpillar is an underground feeder; but about the time when it ought to have formed its cocoon and undergone its change to the chrysalis state it crawled above the surface of the earth, and almost simultaneously the entire mass of these parasites burst through the skin in various parts of the body, and each immediately shrouded itself in a small cocoon of its own, leaving only the shrivelled-up skin of the unfortunate caterpillar within which they had been reared. Mr. Bates inquired whether those larvæ which are most subject to be attacked by Ichneumons are especially conspicuous from their peculiar colouring.

Mr. A. R. Wallace requested members to make observations to assist him to a solution of a difficulty connected with the colours of insects. Mr. Darwin had come to the conclusion that, as a rule in nature, brilliant colouring was due to sexual selection; but in opposition to this the brilliant colours of many larvæ, particularly of Lepidoptera, might be adduced. Mr. Wallace suggested that the brilliantly coloured larvæ were those which were distasteful to birds, and it was on this point that he desired to obtain statistics. If this suggestion should prove to be well founded it would afford a solution of the difficulty. Many caterpillars were known to be mimetic, imitating the flowers on which they fed; others were hairy or spiny, and thus obtained protection from their enemies; some were agreeable and others distasteful to birds. But he had observed that a very slight wound was sufficient to kill a growing larva; and if it was seized by a bird, though afterwards rejected as nauseous, its death would nevertheless ensue: consequently the distasteful larvæ required for their preservation something which would distinguish them from those upon which birds delight to prey; and their brilliant colour was such a distinction, and might supply to the distasteful larvæ that protection which to the others was afforded by mimicry or other causes.

The following papers were read:—1, "On the habits of a species of Phasma found in Jamaica," by Mr. C. B. King. 2, "Notes on the Genus Raphidia," by Dr. Hagen. 3, "Description of Damaster anricollis, a new Caribideous insect from Japan;" and 4, "Notes on Dipelicus (Hope), a Genus of Dynastideous Lamellicorn Beetles," both by Mr. C. O. Waterhouse.

The second meeting for the month of March was held on the 18th, Professor Westwood, V.P., in the absence of the President, being in the chair. Amongst the donations announced as received since the preceding meeting were the "Transactions" of the Natural History Society of Lyons; and the first number of a new periodical work, "Insectologie Agricole," devoted to economic entomology, published in Paris. The President announced that the Council of the Society had in contemplation the publication of a general catalogue of British insects, the different orders to be undertaken by gentlemen versed in each; but inasmuch as but little attention had hitherto been paid to the order Diptera, or Two-winged Flies, the members of the Society were recommended to devote some portion of their attention to collecting those insects during the ensuing season, noticing especially the locality and time of capture of each specimen, so as to furnish the Council with facilities for completing that portion of the catalogue.

Mr. F. Smith read a memoir containing descriptions of a number of new species of Ants belonging to the remarkable family Cryptoceridæ, of which he had already published a monograph in the "Transactions" of the Society. The new species now described were natives of Australia, Borneo, Brazil, and Mexico, and many of them are remarkable for their curious forms. The number of known species now amounts to sixty-eight.

The Secretary also read a paper, forwarded to the Society by Capt. T. Hutton from India, "On Species and Varieties," in opposition to the views of Mr. Darwin, and with especial reference to the modification of the species and races of Silkworms and other domesticated species of animals.

PORTRAITS OF PLANTS AND FLOWERS.

Saccolabium giganteum (Gigantic Saccolabium).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. First grown at the Bishop of Winchester's, Farnham, but recently Messrs. Veitch have had it from Rangoon. It was exhibited at one of the Tuesday Meetings of the Royal Horticultural Society, exciting, as well it might, universal admiration. The flowers, which are more agreeably perfumed than those of S. violaceum, continue in beauty for nearly a quarter of a year. As to cul-

tivation, patience rather than skill is required, the main object being to obtain as large specimens as possible, for the racemes of flowers will be large in proportion.—(*Bot. Mag., t.* 5635.)

Cordyline australis (New Zealand Ti-tree).—*Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia. It is almost hardy in the west of England, and quite so in the Scilly Islands. Slender tree, 12 to 20 feet high; flowers white.—(*Ibid., t.* 5636.)

Tinnea æthiopica (Violet-scented Tinnea).—*Nat. ord.*, Labiatæ. *Linn.*, Didynamia Gymnospermia. Native of Central Africa. Flowers dark carmine, richly scented.—(*Ibid., t.* 5637.)

Dictyopsis Thunbergii (Thunberg's Dictyopsis).—*Nat. ord.*, Smilaceæ. *Linn.*, Hexandria Monogynia. Native of eastern districts of South Africa. Graceful climber; flowers insignificant.—(*Ibid., t.* 5638.)

Dombeya Mastersii (Dr. Masters's Dombeya).—*Nat. ord.*, Sterculiaceæ. *Linn.*, Monadelphia Pentandria. Native of tropical Africa. Flowers white and fragrant.—(*Ibid., t.* 5639.)

Iresine Herbstii aureo-reticulata.—The pale markings on the leaves would be better described as silvery than golden. It is very pretty, but more suitable for table decoration than bedding.—(*Floral Mag., pl.* 333.)

Pelargoniums.—*Milton*, upper petals black, with narrow crimson border; lower petals rose, with darker pencillings. *Negress*, all the petals very deep rich carmine, throat white. Raised by Mr. Foster.—(*Ibid., pl.* 334.)

Lælia albida, *var.* rosea.—White, with petals and lip pink-tipped. Messrs. Backhouse & Son, York, have this Orchid.—(*Ibid., pl.* 335.)

Tapeinotes Carolinæ.—See page 163.—(*Ibid., pl.* 336.)

Cattleya Warscewiczii.—"If we cannot as yet exactly speak of Orchids for the million, we may certainly entertain the notion of Orchids for the many, since it has been discovered that a goodly number of the most charming amongst them—Cattleyas, Lycastes, and Odontoglossums in particular—will grow, aye, and thrive, under what is called 'cool' treatment. Prominent among these Cattleyas is a varied group, which bears the name of the lamented Warscewicz, and which is well represented by the plant selected as our illustration, for which we are indebted to W. Marshall, Esq., of Enfield.

"This Cattleya Warscewiczii is, as we have said, a most variable plant, the imported examples differing in the size, form, and colouring of their flowers, just as a batch of seedling Pelargoniums raised in our greenhouses might vary in these respects. They pass from pure white through every blushing shade to deeply tinted rose, but are all marked by the presence of an orange-coloured blotch on the lip. The blending of colours in some of them is remarkably beautiful. To different forms different names have been given—as Trianæi, rose colour, Wageneri, white, and quadricolor, parti-coloured, but they are all specifically identical, and possibly not even themselves distinct from the better-known Cattleyas, labiata and Mossiæ."—(*Florist and Pomologist*, vi. 69.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

Keep the Dutch hoe in motion during this fine weather, to destroy weeds, and prevent the ground becoming dry and cracked by rapid evaporation. Stir the soil amongst all advancing crops. *Cabbages*, earth up. *Cauliflowers*, water. *Kidney Beans*, sow a few of the Early Negro or Fulmer's Forcing on a warm border, also a number of pots to be placed on a slight hotbed; the plants to be gradually hardened off, and turned out when all danger from frost is over. *Peas* and *Beans*, earth up forward crops, stake if necessary, and make successional sowings of Windsor Beans and of the Marrows and other large Peas. The Victoria Marrow is an excellent Pea, considerably earlier, but not so good a bearer as Knight's Tall and Dwarf Marrows. *Turnips* and *Radishes*, sow on a warm border. If sown in alternate rows, the Radishes will be pulled out of the way of the Turnips. To have the latter juicy and sweet, sow every fortnight till August. The Snowball is an excellent early variety. Follow with the White Dutch, which is the most general favourite in the kitchen. The frames and glasses used for forwarding Cauliflowers, &c., will now be useful for Kidney Beans, Tomatoes, Capsicums, and Cucumbers.

FRUIT GARDEN.

There is no period at which the vegetation of fruit trees is so susceptible of injury from the deprivation of buds or the removal of branches and shoots as the present. No living branch should, therefore, now be touched by the edge of the pruning knife, and disbudding should be commenced with the greatest caution. Except in some particular cases, this operation is not at all advisable whilst the leaf-buds are in the act of breaking. A few of the foreright shoots on the most vigorous branches of Peaches and Nectarines on walls should be first displaced. By frequently going over the trees, and only removing a little at a time, the flow of sap will not be deranged, as would be the case if all or nearly all superfluous shoots were at once removed. Stir the soil at the bottom of the walls, and completely clear away that next the bricks, replacing it with fresh, for broods of insects harbour in such soils and situations. In cold exposed situations plantations of Strawberries made now from plants pricked out last autumn in a sheltered situation, will succeed better if transplanted with balls than if the plantation had been made in the autumn. The ground should previously be well trenched and manured, as no spade ought in future to be inserted amongst them until it is necessary to dig them down. A plantation will stand and produce plentifully many years, if, after bearing every season, the plants are thinned out, so that those left will have their leaves fully exposed to sun and air. Unless for new kinds, there is no method of making fresh plantations comparable to that of turning out plants forced in pots. By this method the Strawberry season can be prolonged until frosty nights set in, and the same plants will produce plentifully in the following June.

FLOWER GARDEN.

Newly-planted trees and shrubs require strict attention in regard to water if they indicate the want of it. It is better to give them a thorough soaking at once, than to afford them a little water frequently, and, after the surface of the ground is dry, fork or hoe it over, and then mulch with short grass to prevent the evaporation of moisture. The same remarks apply to newly-planted annuals, which must be shaded and well watered. In the case of turf which has been recently laid down, after giving it a good soaking of water, dress it over with old tan or leaf mould, and then shade it by covering the ground with pea-sticks or any refuse branches that may be lying about. Put in a successional crop of sweet Peas, and any other annuals that were sown in February. Sow Ten-week Stocks for transplanting. The finer kinds of Gladiolus which have been brought forward in pots may now be planted out in deep, rich, and well-drained soil, but it will be as well to protect with an inverted pot at night until all danger of frost is over. Tulip-beds, &c., should be carefully forked over, and borders that were dug up in the autumn may be lightly forked over now, and all clods broken; it will be much more beneficial than raking them. Plant out Stocks, Rockets, Pinks, &c., in borders or beds.

GREENHOUSE AND CONSERVATORY.

Keep the greenhouse rather close until the plants have sent forth fresh shoots in the new soil, and then expose them gradually to more air. Plants which make their growth in a comparatively low temperature will always endure more hardship than such as are kept too confined and are not so liable to sudden decay. In this, as well as other departments, be particular in watering, and observe that the old balls partake of the moisture. It is best to let plants feel that they just want water, and then to administer a good supply so that every part may be moistened, for if water is given in small quantity the top of the ball is kept too wet while the under roots are suffering. To keep the conservatory now in perfect order you must go over the plants daily, or at least every other day, and take out such as are beginning to decay. Pick off all dying flowers and leaves; also all distorted flower-buds, or, indeed, any small or ill-arranged flowers which do not look well. Every plant at this season ought to be a gem of its kind, or it is not fit to be brought into the conservatory. Some, however, may be useful for cut flowers to fill glasses and for other purposes in the drawing-room. Change the plants often in sitting-rooms, if they are worth preserving afterwards. Roses and all scented flowers that retain their sweetness after drying should be gathered as they begin to fade, and carefully dried at this early season. These, if placed here and there through the rooms, will be better liked by many persons than fresh flowers. Orange trees require particular attention when they are making their young wood. Stop luxuriant shoots at the fourth or fifth joint; no one part of the head should be allowed to grow stronger than the rest. Young trees may require some of their stronger branches to be tied down for a time, which will strengthen the others. Climbers for this house should soon be planted, if additions are to be made this season, and see that the young

growths of the old ones do not become entangled for want of training. Every plant that is intended for a specimen should have the best situation in the greenhouse, and should be turned round two or three times a-week, the shoots should be stopped from time to time, and it should have freedom on all sides. Epacrises and spring-flowering Heaths will bear close pruning after they have done flowering. Correas that have been flowering during the winter should now be rather closely pruned and kept in-doors all the summer, where they will take the place of Fuchsias after September. Luculias that have been at rest since flowering are now beginning to grow again, and should be kept in a low moist atmosphere till the eyes break. Forcing the Luculia at this stage, or even encouraging it to make an early growth, was the principal cause of failure on its first introduction.

STOVE.

The lately-shifted plants will now be making roots, therefore attend to watering, and see that they do not suffer from want of this. Maintain a warm and moist atmosphere, especially during the day, that the growth may be accelerated as much as possible. Shading will also be requisite when the sun shines fiercely, but dispense with it as much as possible, and admit air when the temperature exceeds 90°; but with such a temperature the humidity must be kept up, or the plants will soon suffer in their foliage, and as the foliage of the plants is just as important as the flowers, great attention will be necessary at this critical period; the young leaves are very susceptible of injury, and one half-hour's negligence may place you six months in arrear.

FORCING-PIT.

In many places these pits are now as full as at any former period. The overstocks of duplicates and condemned specimens, parcelled out at potting-time, are put in here to see what flowers or cuttings they may produce before they are finally thrown away. Hedychiums to flower late in the summer may now be started, and another crop of Tuberoses put in for succession. Primula sinensis for flowering in September should now form little stocky plants fit to be planted out in cold frames by the middle of May, and more seeds of it should now be sown. Gesnera zebrina and longiflora, both tall flowers, should now be pushed on by all the heat and moisture at command. As these pits are generally the last places for spring propagation, and as the work does not admit of large portions of air being given, they must be regularly shaded in hot, dry weather: thin bunting or calico should be used for the purpose; mats darken too much.

PITS AND FRAMES.

Proceed with potting-off all plants for bedding-out; those which have been established and hardened may be removed into temporary pits, and covered with mats. Some neat and very convenient permanent structures for protecting plants in small pots may be seen in the nursery of Messrs. Rivers.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

This has been a very busy week as regards out-door work. Sowed in excellent condition a good breadth of *Onions*, and will wait until the seedlings begin to peep up before giving the ground a rolling. In light soil and in such dry weather would have rolled at once. In either case, as soon as the seedlings show above ground it is advisable to run a Dutch hoe between the rows, to cut down young weeds, and prevent the ground cracking; this hoeing to be as shallow as possible, so that the ground may be left firm though having a rough surface. We shall select a poor hard piece of ground merely loosened on the surface, for sowing the Silver-skinned Onion for buttons and pickling. There is often a difficulty in obtaining these small enough in heavy ground—so much so, that it is not uncommon to give large Onions for less than half the bulk of small ones. We have often secured small bulbs by taking the thinnings of the main crop, and laying them in thickly in sandy soil, so that they could grow but little; but these are not so well and flatly formed as those obtained in hungry soil from the Silver-skinned. Transplanted also a piece of winter Onions in rows 1 foot apart and 4 inches asunder in the row, chiefly White Spanish and Tripoli. These were not quite so large as a crowquill, and at that size they generally do admirably transplanted—in fact better than if left where sown in the previous autumn, and where those left will be useful for salads until those sown under protection come in for that purpose. In some places they are relished at table when not larger than good-sized stocking-needles, and for those who like Onions the flavour is said to be very rich when the Onions are of that small size. When used so young frequent sowings are wanted in-doors all the winter. In transplanting Onions the chief consideration is to fasten the roots firmly in the ground without burying any more of the bottom of the stem than can be avoided.

Sowed also Parsnips and Carrots, and will sow more of the latter and Beet, Scorzonera, &c., a fortnight hence. Sowed Pine Apple Beet under protection, to be afterwards transplanted, as for a number of years, even with the precaution of netting, we have not been able to secure a good crop of Beet, nor of Prince's Feather or Love-lies-bleeding in the flower garden, without planting out good-sized plants. The birds here seem determined to nip up each of these coloured plants as soon as the seed-leaves appear.

Peas and Beans.—Sowed more of these, the former generally at good distances apart, with lower crops between, as Potatoes and Cauliflowers. For Peas, we have used some of the cheap 2½-inch-meshed wire netting, 24 inches in height, advertised in our pages, merely bending it in semicircular fashion over the rows, and fastening it at the sides with a few hooked sticks, and as yet neither partridges nor pheasants have looked near the netting; neither of them will be able to push their necks far enough in to reach the Peas. Peas planted out are growing very well.

Cauliflowers under glasses have been finally thinned out to four or five large plants in a light. The glasses were raised considerably to give the plants room, and the soil well mulched with rotten dung, and well watered with manure water. The plants were kept sturdy and hardy all the winter. In the two periods of severe cold attended with snow they were kept covered up with litter until the frost was over; but now in the fine weather we care not how fast they grow, and early Cauliflowers will be acceptable this season. Not a plant has been touched this winter or spring. Last season we had scarcely a plant that was not levelled to the surface of the ground with rats and mice. The vermin have been pretty well thinned since then; but there are no doubt other reasons why vermin commit great ravages at one time and refrain from doing so at another. Ere long these Cauliflowers will be freed from the glasses entirely, the plants bent outwards to give them full room, the ground between used for banking them up well, and then a fair allowance of manure water causes them to head well. Planted out a good piece in the open ground, and, not being sure of the weather, stuck some Laurel branches between the rows. Pricked out a lot sowed on a bed along with Celery.

Cabbages.—Gave a good deep hoeing among the most forward, because we want to encourage tops here instead of bottoms, as in the case of the Onions. With all our care our Cabbages will be but moderately early. We detailed some time ago that of our plantation made in the autumn not one plant was left by midwinter; the rabbits and hares had cleared the piece, though surrounded by twine netting, but which they bit and tore to make their way through. They in their ravages served this good purpose, that a web of galvanised wire netting was placed round this rather open part of the kitchen garden, and no four-footed intruders have found their way in since then, though they have tried very hard at the gates. Our most forward Cabbages, owing to these circumstances, will be from plants much smaller than those planted out, taken up, potted in 60-sized pots, and turned out when the pots were full of roots, the rooting being encouraged under glass. The most forward of these will be little behind those planted in autumn, but of course they have cost more trouble. Planted out a piece of small plants, autumn sown, to succeed these.

Some of our Broccoli has been much injured; even of the hardy Purple Sprouting many plants are killed outright, whilst in the same rows other plants are in great luxuriance, though exposed in every way to the same circumstances during the winter. Our London Coleworts, too, which, after yielding young Cabbages up to the new year, would often have their stumps killed by the frosts after that period, have mostly stood this season, and are well furnished with young sprouts all round the stem. This result is, no doubt, owing partly to the protection they received from the snow.

Took the opportunity of planting a good piece with Potatoes, and would have done more only the ground was moister than

we liked; but if the weather continue dry, we hope to finish this work shortly. Some of our vegetables, even tall Brussels Sprouts and Cottagers' Kale, are so much like bare poles, from being so often picked and gathered from, that though we cannot yet afford to remove them, we mean to dig the ground all over, and plant Potatoes between the rows, leaving spaces for Peas, &c., as the Greens will all be removed by the time the Potatoes are above ground, and the spaces occupied by the Greens can be forked over again. Such means must often be resorted to where much produce must be obtained from little space.

Forced vegetables as in previous weeks' notices. We may merely state in reference to *Sea-kale*, that not having any Sea-kale pots, and not wishing to lift much more, we covered a lot of the most forward with ashes, as we did not wish to use litter, and after placing a cone of ashes over some of the rows farthest advanced, we put on a common garden pot, with a piece of turf over the hole; but before setting the pot on we placed inside of it rough dry hay pressed against the inside of the pot, leaving a hollow space in the centre. The reason for doing this was, that exposed pots, provided they did receive a little warmth in a sunny day, in cold weather and in frosty mornings radiated heat so freely that the inside of the pot was often colder than the external air; and this covering of dry litter, whilst it will permit of the air inside being heated, will prevent its being suddenly cooled, a matter of importance when early cuttings out of doors are wanted, without the help of litter or fermenting material outside. Thus treated we find the plants under some pots will bear cutting ere long, whilst others not so treated are doing little more than showing the buds above ground.

FRUIT GARDEN.

Besides the usual routine of firing, watering, air-giving-thinning, tying, &c., the chief work has been moving Straw, berry plants well set in the Peach-house, where they had the advantage of a roof with an angle of 45°, to pits where they could have a warmer, closer atmosphere to swell the fruit off, and plenty of air to give colour and flavour. They would have swelled admirably in the Peach-house, only that was our best setting place. Placed, also, two rows in the front of the orchard-house, where they did well last year. In placing such plants we remove the greater portion of the old leaves outside, run a pointed stick, or the point of a knife, round the surface soil, shake a little off, and replace with rich compost. As the trusses show there will be plenty of fresh leaves, and the old outside ones take away more than they give, whilst the object at first should be to throw all the vigour possible into the flower-trusses. Some time ago we mentioned that mice had begun on some plants in a frame. They, on the whole, did less damage than we imagined, as in most cases they had cut off the outside leaves and left the centre, so that many of the trusses suffered but little. This is not generally the case, as in most seasons mice nibble the central bud and leave the outer leaves alone.

In the first orchard-house the beauty of the bloom on the trees on the wall, and on trees in pots in front, is beginning to be on the wane, and the setting is proceeding well. In the other house, which we are keeping back, the Peaches and Plums are in full bloom, but except some early Cherries, the bulk of those in pots have not yet opened their buds, though swelling fast. From a few Apricots in this house the blossoms are falling, but a sufficient number seem to be set. The Apricots have always had a little air, even in cold weather. The sun which came so opportunely has rendered us careless this season of wind-boards, brushes, &c., for dispersing the pollen and assisting the setting. One thing here it may be of importance to mention, the roots of the trees against the wall run through the bed on which the trees in pots are placed in front. With the exception of the liquid necessary to keep plants in pots and Lettuces in health in winter, the ground in these houses has been rather dry all the winter, and up to the time of the trees against the back wall swelling their buds. In the severe weather of March we did not like the idea of a wet surface inside the house, but as the milder weather came, and the buds began to open, we gave a good watering to the ground, but at three different times across the house, at a week's interval, doing about one-third of the width next the back wall first, then in about eight days one-third more, and then again that nearest the front. This plan secures moisture for the swelling and setting buds, and prevents too much excitement to the roots at one time, which might tend to throw the buds off. Extra dryness, and extra moisture, are alike prejudicial. It is wise to guard against sudden extremes. The dry surface soil in winter and spring is a great security against frost and extreme cold.

ORNAMENTAL DEPARTMENT.

In-doors the work has been chiefly confined to moving plants, potting, putting up rough-and-ready hotbeds for cuttings, sowing seeds, making preparations for turning lots of bedding plants out under protection, and sowing annuals under a little protection, to be lifted in patches, and transplanted.

Turfing.—Much time was taken up in fresh turfing, which would have been done earlier had the weather permitted, and for which we allowed other work to stand in abeyance, in order to have it done whilst the ground was moderately dry and the weather dry overhead, well knowing that if turf is laid now there is enough of moisture in the ground and in the turf itself to set it growing at once without having to water it afterwards.

Provided the turf is laid down, and moderately beaten and rolled, it may have more beating and rolling after wet at any time. There are a few essentials to good turfing. First, the ground should be made of the requisite level, and moderately firm, and left with a raked surface. Second, the turf should be taken up of as uniform a width as possible, and more especially uniform in thickness, as then there is little necessity for much packing. When not uniform in thickness the turf must be left uniform, either by removing soil or adding fresh as necessary, for if a fine level or regular sweep is aimed at it should never be forgotten that if the turf is not left level no beating or rolling will ever make it thoroughly as it ought to be. Third, when there is a large space of new turfing to do, it is all fair sailing, and the above attended to, it is scarcely possible to go wrong, but when flower or shrubbery beds are to be turfed, and to be left level with the lawn between and beyond, then the beds should not only be levelled and well beaten with heavy mallets, but even then the soil will be so apt to sink in time more than the old lawn, that the fresh turf after being well beaten should be left half an inch or so higher than the old turf, and will then be low enough by midsummer. Where great nicety is required, and the space between the beds is not very wide, it is the best plan to level the beds, take up the turf between, loosen the soil there, beat down as in the beds, and then make all level, and turf all over. This is generally the best and most economical plan in the end; for in all such piecing of turf as is referred to, with the greatest care and practical judgment there will frequently be heights and hollows in the course of six or twelve months, which, though unnoticed by the proprietor and his friends, will be found out by the practical man who looks for them. Fourth, for making a good lawn at once there is no plan equal to turfing. Fine green turf looks best, but the roughest turf well mown previously, and cut so thin, say rather less than an inch, so as to get rid of most of the root weeds, will make a very good lawn in a few months. Fine lawns are made in a longer time by obtaining the best seeds from respectable firms. A sort of compromise is made between the two modes by piecing the ground with rough pieces of turf cut or rather torn apart. To do this best, the ground, after being levelled and made firm, should be rather deeply raked on the surface; the turf is laid, say in pieces of 3 inches square, from 3 to 9 inches apart, but the more rough at the sides the pieces are the better, and as a space is done fine Bents and Dutch Clover are sown thinly in the intermediate spaces, the pieces beaten, and then all rolled. Such piecing will soon make an excellent lawn without sowing, but sowing affords a quicker result.

For immediate effect there is nothing like turfing, and the roughest grass in a park or pasture will, if mowed closely and treated as above, make a most beautiful lawn. We have known cases where new pleasure grounds were made out of park or grass lands, in which the old grass was dug down, the country scoured for turf, and considerable expense incurred for repeated sowings, when the grass sods that were buried, if mowed closely and removed before the necessary levelling, might have been laid down again with the very best results.—R. F.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We understand that Sir Robert Peel, Bart., M.P., has consented to take the chair at the annual festival of this Society, which is to take place on Thursday the 27th of June.

TRADE CATALOGUES RECEIVED.

John Morse, Dursley, Gloucestershire.—*Catalogue of Cuttings.*

Thomas Sampson, Preston Road Nursery, Yeovil, Somerset.—*Catalogue of Bedding Plants and Roses.*

COVENT GARDEN MARKET.—April 10.

The remarks in our last week's report continue to apply to the state of the market generally. Quotations for some articles are rather lower.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Flowers in Drawing-room (*H. B. J.*).—We cannot possibly tell what book will aid you in keeping up a display of flowers in your drawing-room, unless we know what means you have of cultivating them. The sprig you enclosed is of Deutzia gracilis.

Privet Berries Poisonous (*R. S.*).—There is no doubt that the berries of the Privet (Ligustrum vulgare) are injurious, and to very young children have proved fatal. Last year a child two and a half years old died from eating them. The case is reported in the "Medical Mirror."

Hays's Constant Stove (*Drina*).—One of the stoves would exclude frost in ordinary winters from a house 15 feet by 8 feet, but it would not answer, we think, for propagating purposes.

Slate Tubs for Orange Trees, &c. (*Kit*).—They may be had of Mr. W. Beck, Slate Works, Isleworth.

Back Number.—If "Engworth" wants the first Number (January 2nd), for 1866, and will send me his address, I will send the Number to him.—Henry H. Cave, *Brigg, Lincolnshire.*

Mulberry (*B. P. Bartlett*).—There is no stock for grafting this fruit upon that would hasten its coming into bearing. We have heard of large branches being planted, which rooted and bore fruit long before the trees from small cuttings were productive.

Modes of Vine Training (*J. Bowlby*).—There are some Vines, such as the Golden Hamburgh, that bear best on the young wood; and in other Vines there are circumstances, such as when the roots are deeper than desirable, in which the Vines will bear freely on last year's canes, when they will not bear so freely if closely cut back on the spur system. In ordinary cases in spur-pruning, when the spurs get away from the stem, the bringing up a fresh shoot from the bottom will permit of the main shoot being replenished and the old one cut away without any break in the house. For instance, if last year's shoot was cut down to 4 feet in length, then the spurs on the old main rod could be cut off for that height; next year a piece more may be denuded of its spurs, and the third year the whole cut off at the bottom. Under this plan the Vine would have no more to do than before. It is a very doubtful point, however, whether a Vine increases in energy in proportion to the limited space it occupies. If your Vines are so young and doing well, we do not see the importance of the fresh-rod system; but we know it is a good plan if carried out. Of course when this one rod is encouraged, fewer laterals are left on the old bearing rod.

Muscat Vine Weak (*An Old Sub.*).—We should think your Muscat Vine is merely righting itself, if the account of the state of the roots, &c., is correct. The energies of the plant were paralysed by cropping too early. We have known Vines bear heavily the second season, but it required years to bring them round. The breeder of horses knows the folly of working a foal too early, and many Vines suffer from having so much to do when young.

Vines Unproductive (*John Baker*).—Unless you have good experience, it is too late to do more with the border this season than make holes to see that there is no stagnant water about the Vines, and encourage these to grow as much as possible during the summer; and as they are so weak, encourage young shoots from the bottom, one from each Vine, so as to cut out the spurred rods next season. In the beginning of October lift and replant the roots in a suitably drained, prepared border, and during the summer you could be preparing the materials.

Ribbon-borders (*Constant Subscriber*).—We answer every communication that reaches us. We have given so many examples of ribbon-borders, that a fancied list of arrangements now would do little good, and even then every correspondent would like his own particular case considered. Your proposed arrangement will do very well—namely, Cerastium, blue Lobelia, yellow Calceolaria; Tom Thumb, Christine, and Scarlet Pelargoniums, the last at back and to be higher, but if you had a white row or white-foliaged Pelargoniums between the two scarlets, such would be more effective than Christine. A purple or a blue, high enough, would also be better than a pink between two scarlets. Some people, however, admire this combination, and much of the interest of the border will depend on the planting, and the heights being suitable. On the latter account we doubt if your dwarf, white-leaved, creeping Cineraria will do as well or be as compact as the Cerastium. In fact, we doubt a little if this creeping plant is a Cineraria at all, and rather think it is an Arctotis, which, however interesting, does not make so good an edging plant as Cerastium.

Gauze for Fruit Protecting (*Old Subscriber*).—Mr. Keane informs us that the shading used extensively for fruit trees is called "Brown's floral shading." It is a gauze of cotton, and is tacked over the fruit trees and left on night and day during the blooming season. It is used by Mr. Grieve, gardener at Culford Hall, Suffolk, and many others, and is sold in pieces at all large London seed establishments.

Asphalt Walks (*T. W.*).—The following is the mode of forming them:—Take two parts of very dry lime rubbish, and one part coal ashes, also very dry, and both sifted fine. In a dry place, on a dry day, mix them, and leave a hole in the middle of the heap, as bricklayers do when making mortar. Into this pour boiling-hot coal tar; mix, and, when as stiff as mortar, put it 3 inches thick where the walk is to be. The ground should be dry, and beaten smooth. Sprinkle over it coarse sand; when cold, pass a light roller over it, and in a few days the walk will be solid and waterproof.

Removing Camellias (*W. S.*).—We would certainly remove the Camellias now if they have not started into growth; but if they have it would be better to defer moving them until the growth is complete, and then perform the operation carefully. There is nothing better for Camellias than a moderately light turfy loam, the turf being pared off 1½ inch thick, that part only being used.

Poinsettia Culture (*A Subscriber, J. B.*).—You should at once place the plants in a temperature of 65° at night, and in a moist atmosphere they will soon start into growth, water being sparingly given. When the shoots are an inch or two long repot the plants in smaller pots, using a compost of equal parts of turfy loam, peat, and leaf mould, and adding sand liberally. Keep them close and shaded for a few days, then place them near the glass, and take out the points of the shoots when these are 3 inches long. Shift the plants into their blooming-pots (they are generally required in small pots), early in June, and if placed in a light and airy situation, and afforded the ordinary treatment of stove plants, they will bloom in autumn. You may take off the shoots when they are about 3 inches long quite close to the stem. Insert them in silver sand, plunge in a hotbed, and cover with a bell-glass; they will be well rooted in six weeks. If then potted off, repotted in July in five-inch pots, and not stopped, they will afford a fine bloom in autumn and winter. They require a position near the glass, a moderate amount of air, a moist growing atmosphere, and copious waterings.

Cutting Down and Grafting Cereus hexagonus (*C. M. Major*).—Now is a good time to cut down the plant, the upper part being left on a shelf for the cut to heal over, and then putting it in sharp sand. This is also a good time to graft the different kinds of Epiphyllum upon the stump; we would use exclusively the kinds of pendent habit, but you may employ any of the trailing kinds of Cereus also—kinds that will best suggest themselves to you.

Early Spring-flowering Plants (*B. B.*).—Hepaticas, double and single blue, single white, double and single red; Primroses, the single and double yellow, double white, lilac, crimson, and purple; Daisy, double crimson, pink, and white, also double crimson with gold-striped leaves, very handsome; Polyanthus, single and double. Of Violets, the single and double blue, Russian varieties, and the lavender blue Neapolitan, the sweetest and best. Draba aizoides and borealis, yellow; Primonaria mollis and officinalis, purple and red; Viola lutea, yellow; Cheiranthus Marshalli and longifolius, brown and yellow; Arabis mollis and mollis variegata, also alpina and its variegated form, all white; Alyssum montanum and saxatile compactum, yellow; Aubrietia deltoidea and purpurea, purple; Orobus veruus, purple; Phlox alpinus Nelsoni, white; P. verna, rose colour. In addition to the above, Tulips, Hyacinths, Crocuses, and Snowdrops, Scilla sibirica, and S. bifolia, Winter Aconite, Narcissus angustifolius, N. juncifolius, and Iris reticulata. The best time to plant all the above where they are to bloom is early in autumn. They may be obtained from any of the principal nurserymen.

Training Roses against a House (*Idem*).—The best material is No. 12 galvanised wire horizontally placed, parallel with the courses of bricks, or about 3½ inches apart.

Bignonia radicans Propagating (*M. C.*).—The plant is readily increased by layers, and by cuttings of the young shoots taken off with a heel, and placed in sand in a mild hotbed. Cuttings of the half-ripened shoots also strike freely in a hotbed. The colours of the flowers vary much with the soil and situation, and there is variety named B. radicans superba, an improvement on the species.

Outside Border of Vinery (*An Amateur*).—Arrange the flowers you mention in your border thus, beginning at the back—Perilla nankinensis, Aurea floribunda Calceolaria, Tom Thumb Pelargonium, Variegated Alyssum, and Lobelia Paxtoni, a row of each. We do not advise you to plant the border, but you say you "have made up your mind" to do so.

Grass on Mortar Rubbish (*Mortar*).—The heap of old mortar rubbish 2 feet deep will not grow grass unless you cover it with soil, for which purpose road scrapings will answer.

Turning Gravel of Carriage Drive (——).—The best plan is to make an opening at one end down to the rough or foundation gravel, if any, and, after picking up the drive, place the top at bottom. All the weeds are thus placed at the bottom and they must perish, but when the gravel is sifted it is clear that some of the former surface must be near the top, and that the liability to weeds is increased. The softness of the part done before the snow is easily accounted for by the wet having gone down among the gravel before the latter had become firm from rolling. It will be all right after the high places have been picked up and put in the hollows, and well rolled.

Wallflowers, Carnations, and Pinks Destroyed (*Idem*).—Your loss is mainly to be attributed to the taking up of the plants at so late a season, and exposing the roots to the atmosphere. It would have been better done in the end of March or early in April; but old plants are at any time difficult to move. No doubt the severe weather, combined with the moving, is the cause of death. Ours are not in the least injured, except the Wallflowers.

Viola cornuta (*Idem*).—It is more a Violet than a Pansy; both are Violets botanically. Viola cornuta makes a good small bed, but is best as an edging.

Oleanders not Flowering (*W. M. S.*).—The most probable cause of their not flowering is a deficiency of heat. If you were to place them in a vinery at work we think they would expand the buds. You cannot afford them too light a situation, and if you give them that and abundance of water when expanding their flowers and making new growths, there is no fear of their not blooming. They should be kept dry in winter, but not so much so as to affect the foliage. The pots may be set in water when the plants are growing vigorously.

Azaleas from Grafts or Cuttings (*Inquirer*).—It is incorrect to say a fine Azalea plant cannot be obtained from a cutting. We have had many, and, in fact, most of the plants exhibited are from cuttings. The only advantage in grafting is, that a plant is obtained sooner, and is of freer growth.

Estimate of Coal (*Waste Not, Want Not*).—We do not perceive any mistake, only it now occurs to us that we did not take the cinders into account, which, from what you say now, would be almost sufficient for the heating of your glass structures. The amount of coal we named was that which we knew to be consumed in a similar establishment.

Mistletoe (*Charley*).—We think it would grow in almost any part of Ireland. It will grow on the Crab, Apple, Thorn, Lime, Poplar, and Oak, and is occasionally found on the Pear. It is seldom that Violets come double from seed, but they do occasionally.

Names of Plants (*South Croydon*).—The Salvia is probably fulgens, but the corolla alone is insufficient to distinguish it from some others. The Cytisus with a terminal raceme of flowers is C. stenopetalus; the other C. canariensis. Genista differs from Cytisus in usually having 1-foliolate leaves, and in the calyx. Coronilla differs from both in the jointed pod and one free stamen; in Genista and Cytisus the stamens are all united into a tube. (*Wellwisher, M. H.*).—1, Senebiera didyma; 2, Salsola Kali. (*B. P. J.*).—1, Eriostemon hispidulum; 2, E. intermedium. (*H. O. T.*).—Begonia natalensis. (*Sevenoaks*).—We cannot venture to name your plant from the leaves only, as there are several with similar ones. (*R. F.*).—Burchellia capensis. (*A Subscriber*).—Petunia nyctaginiflora; 1, Erica propendens; 2, Erica. (*W.*).—Justicia carnea. (*J. W. Burbidge*).—It is Vanda tricolor. The drawing is faithful, and with a little instruction you would draw flowers successfully. Of the communication we have no recollection. We never notice the rejected.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 9th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BREEDING DARK BRAHMA POOTRAS.

The letters of "Nemo" on this subject have been most interesting, and I desire to thank him for them. I have so often, perhaps too often, intruded my ideas in your columns on my favourite breed, that I fear I may be trespassing on space, but as every editor has a refuge for the slighted contribution, I must only say, if so, consign me "to that bourne from which no" manuscript "returns."

Mr. Fowler is as old an exhibitor of Brahmas as I am, perhaps a year or two older. I cannot exactly see why he thinks I should disagree with his notion of a good Brahma. I have always striven to make colour less essential than some appear disposed to make it; yet if I have a preference, it is certainly for the silver-grey ground in the hen, and I have no objection to a whitish throat, though I prefer the breast well pencilled. As to the cocks, we are perfectly agreed. I greatly prefer the spotted breast. I dislike exceedingly the bronzing of the wing, so frequently seen, and although I should prefer the thighs black, yet I should not discard a cock that had some white there, if otherwise good.

I believe that this grey colour in the hens is far less likely to pass into the reddish brown with age, than is the darker colour now more sought after. I think I may say, therefore, that as regards colour Mr. Fowler and I should be quite agreed.

The best colour, the most brilliant pencilling, the neatest combs, cannot, in my humble opinion, make amends for failure in other points. "Nemo" has remarked that the distinctive points are the pea comb and the feathered leg. I recollect the early days of Brahmas, so of course does Miss E. Watts, as her's were amongst the earliest birds; her's were always pea-combed; but many others, and notably Dr. Gwynne, of Sandbach, preferred and retained the single comb. Mr. Sheehan again had the single comb in his yards, and a cockerel I purchased of M. Garbanati, which came from that strain, had a single comb—nay there was a judge, possibly dead now, as I never see his name, who would not look at the pea comb, and who passed over two pens of my own at the Hereford Show simply because they were pea-combed.

The pea comb or triple comb, now considered a necessary adjunct to Brahmas, is not, however, peculiar to them. One of the neatest I ever saw belonged to a mongrel, and often as in my rides I saw this bird I coveted the comb for transplantation. I think, however, before I had ever seen the pea comb on a Brahma, I had seen it on a cross between the Spanish and Cochin. It does seem very strange that the cross between two single-combed breeds should produce the pea comb, but in a sitting of these cross-bred eggs that I hatched before I kept Brahmas, seven or eight chickens had good pea combs. My memory also seems to say that in the old "Poultry Chronicle" some correspondent had also noticed this; he went further, thinking in those early days to settle the Brahmas for ever, he suggested that their pea comb was derived from some cross. I have also seen capital pea combs on otherwise good Malay birds.

I may sum up my own ideas about the combs thus—I like them small, firm, free from twist, and the grain of the skin fine, but I do not think the points of the comb nearly so essential as the leg.

Before the introduction of the Cochin and Brahma no large breed of fowls having feathered legs and covered hocks was known. These two points distinguished them from all others. I am not so certain that the feathered middle toe is not a later addition, but it is welcome; from the hock downward to the foot, the feathering cannot be too profuse and ought to be heavy, especially just below the hock. Again the thigh must be fluffy, and these soft fluffy feathers ought to curl round and hide the joint from view when looked at posteriorly. I am not going to enter on the vulture-hock question. I have been taken in your pages as an advocate of the extreme hock—this is quite a mistake. If the feathers are soft, and curling round the joint, I should not object to an inch projection, but the essential point is the joint must be covered. No Brahma can be true that has this naked, and I would myself disqualify a bird, however good, if it failed in this essential. This fault

would be certainly attended by a poorly feathered shank. "Nemo" in his paper on crossea refers the poorly-feathered leg to Dorking blood. I can hardly agree with him; the feathering can be made and easily made as heavy as ever, but the fifth toe is persistent in a wonderful manner, and is far oftener seen than even the cruel expression which I certainly have myself noticed as often an attendant on Dorking blood. Another symptom of Dorking taint is the length of the tail; this would always arouse my suspicions.

Whilst at combs and hocks let me bestow a word on "Falcon," and his suggestion that the stiff hock feathers should be removed in the same way as the Game cocks are dubbed. I may be, perhaps, considered as eccentric as "Falcon" if I say that I think there is much force in his remarks. For what purpose is dubbing the Game cock still permitted? Clearly only for the sake of appearances. It is ridiculous to reply that Game cocks must be shown as if ready to fight. Were this correct various other dubbings ought also to take place, and these certainly would extinguish any prize-taking in the exhibition pen. Recollect that in dubbing the Game cock a most faulty comb may be actually got rid of, a comb that would disqualify for prize-taking. Now if merely for the sake of improving the appearance of the "Coq d'Angleterre" we still permit dubbing, why should we, for the sake of appearances, refuse far less painful performances in other breeds?

These thoughts had already been running through my mind when early in this year I was amused by the virtuous indignation of your reporter at one of the northern shows, where some threads were discovered in the comb of an otherwise first-rate Hamburgh cock, and the bird was disqualified. Your reporter in defence of his remarks enlarged on the excessive cruelty, &c., holding up the owner to scorn. Surely there were Game fowls at that show, and on the score of cruelty their owners were much more to blame. I cannot say positively, but it strikes me that to achieve the perfect dubbing I have seen in some of our Game strains, more than one operation must be necessary. If correct in this supposition, Game owners have more sins to answer for on the score of cruelty than the owner of that Hamburgh cock.

Again, the trimming that takes place over the eye at the base of the comb in both Game and Spanish, for the latter in this respect are most extensively trimmed; what is it done for? to improve the appearance. Why should it be legal, for the winking of judges at this practice renders it legal, to pull out objectionable feathers at one part but not at another? Why should the Game and Spanish be improved by art, whilst the Brahma and Cochin must be shown as Nature formed them? Can it be that these latter breeds have more beauties naturally, and, therefore, require no assistance from art?

In conclusion, let me congratulate my Brahma brethren on the position our favourites hold at Bury St. Edmunds. It appears to have excited the splenetic feelings of "Dorking Cock" at "Dorking Castle," but we need care little for that, evidently the poor old fellow has bumble-foot, and, I fancy, too, a touch of the gout in it; perhaps, when he did thrash Brahma in fighting, the latter trod on it—any way a little magnanimity is required to "adorn a throne," and that quality either from the gout or something else "Dorking Cock" appears to be deficient in. He is evidently getting blind also, or he would have noticed that Dorkings are offered Chicken prizes at the Royal Agricultural Show, a compliment paid to no other breed; this renders his remarks quite out of place. "Coq d'Angleterre" is also irate enough, he would knock the Brahma down not for the sake of putting "Dorking Cock" in his place, but evidently he would put himself, the Game, on the throne.—Y. B. A. Z.

A YEAR'S POULTRY-KEEPING.

Looking over my poultry book for last year, I find the profit to have been 6*s*., allowing 5*s*. per pair for Ducks and fowls, and 1*s*. 8*d*. a score for eggs, which, considering the high price of both, I take to be somewhat under the mark, particularly as I consider that for actual weight of flesh two of my fowls are equal to three that I should purchase at the poulterers'. My birds have the run of a good yard, but are entirely dependent upon me for their food, which is given to them twice a-day, and in the morning consists of meal and middlings mixed into a paste with scraps from the house, and in the afternoon of whole barley or wheat, or sometimes oats, whichever I can meet with most conveniently. I have a Cochin cock and fourteen hens, four of them Cochins, two Hamburghs, two Spanish, two Dorkings, and four cross-bred.

Subjoined is my account:—

	Eggs.		Eggs.
January	40	July	78

Leaving 6*s*. for my trouble, which I look upon in the light of a pleasure, and so I think would every active healthy lady who once took up the pursuit.—Bedfordshire.

CROSSING GAME FOWLS TO PRODUCE DIFFERENT COLOURS.

To produce Brown Reds.—Put a Black-breasted Red or Ginger Red cock to Dark Grey or Dark Birchen hens. Pile cocks and Red Dun cocks will also produce them with the above-named hens; this cross also throws Duckwings.

To produce Black-breasted Reds.—Put Brown Red, or Ginger Red, Pile, or Red Dun cocks to Duckwing hens. Brown Reds put to Duckwings also make Dark Birchens and Greys.

To produce Duckwings.—Put Dark Grey, Dark Birchen, Mealy Grey, or Yellow Birchen cocks to the Partridge hens. The first-named two will also throw Brown Reds as well.

To produce Piles.—Put White cocks to Red Dun, or Ginger Red, or Partridge and Cinnamon hens.

To produce Dark Greys and Dark Birchens.—Put a Duckwing cock, or Mealy Grey or Yellow Birchen cock to the Brown Red hens, which will produce them best.

To produce Red Duns.—Put a Blue Dun or Dun cock to the Wheaten-coloured or Cinnamon hens of the Black-breasted Reds of that colour. Blue Dun cocks with Duckwing hens make the Birchen Duns.

To produce Brassy-winged Blacks.—Put the Dark Birchen, Yellow Duckwing, or Yellow Birchen cocks to the pure-bred Black hens, or the reverse of this.

To produce Yellow Birchens.—The Yellow Duckwing cock put to Ginger Red hens or Cinnamons does this.

To produce Ginger Reds.—Put Pile cocks to the lightest-coloured Partridge hens of Black-breasted Reds.

To produce Mealy Greys.—Put the White cocks to Dark Grey hens. The lightest Dark Grey hens are the best.

To produce Red Furnaces or Red Mullingars.—Put White cocks to the reddest Red Dun or reddest of the Cinnamon hens. These make Spangled Piles.

To produce Spangles, use Whites, Blacks, and Cinnamons. A White or Cinnamon cock is best.

To produce Polecats.—Use Partridge hens put to White and Black cocks. All three colours are required.

By this it will be seen that the three original wild colours are easily producible by crossing, while Whites, Blue Duns or Duns, Cuckoos, and Blacks can only be produced by occasional, or accidental throws, as the result of domestication.

"Whites, Duns, and Duckwing Greys" mixed, will sometimes throw Cuckoos. Crossing will not make Whites, Duns, or Blacks; but this does not at all prove these colours to be original. All these crosses are, however, certain to produce much inferior birds to the true made or original breeds for a length of time, and are, therefore, undesirable and even foolish, except for the sake of experiments.

Piles are called the most mixed blood of all by some breeders, but this is not always the case, and not so much so as is generally thought.

In breeding and crossing, it must be observed that though the Grey breeds are almost always harder and stronger than their respective Red originals, Dark Greys harder than Brown Reds, and Duckwing Greys than Black-breasted Reds, yet in breeding crosses the red colour is much more powerful than the grey colour, though Red birds are less strong and hard than Greys, and all the Greys incline wonderfully to breed back to the Reds they sprung from, especially in the cocks. I have known Pile cocks (red eyes and white legs), when put to Dark Grey hens, throw good Silver Duckwing Grey cocks

(white legs and yellow pearl eyes). I also know two breeders who both had Black-breasted Red cocks mated with Duckwing hens, both willow-legged, and neither of them could ever obtain a single Duckwing cock chicken, though Duckwing Grey pullets were freely thrown, as were Partridge pullets, but all their cock chickens were Black-breasted Reds. This does not agree with those who assert that Duckwing cocks are easiest thrown from the Black-breasted Red cocks. I have always found that if you want good Duckwings, cocks especially, you must breed from both Duckwing cocks and hens, and not from mixed colours. Duckwing cocks are no more liable to spotted breasts than the Black-breasted Reds are to brown-spotted breasts.

I should have mentioned in the former papers, that good solid corn and peas are far preferable to all sloppy, pulpy-made mixtures as food for Game fowls, as hard corn and peas harden both flesh and feather.—Newmarket.

COMB OF THE BRAHMA POOTRA.

In corroboration of the remarks upon combs, contained in the very able communications of your correspondents "Nemo" and Miss E. Watts, I would observe that out of eighty-three Brahma cockerels reared by me in 1866, I have only one with a perfect comb, and to test the judge's knowledge and observance of its comparative scarcity, I exhibited the bird only once, when he was not even mentioned. He is rather a small bird, of beautiful colour, hackle well defined, and short legs not very well feathered. Thus you will see that with many good points, and one not to be surpassed—his comb—he appears to be unfit for exhibition.

As "Nemo" truly observes, there is no fowl bred with a characteristic so peculiarly distinctive as the perfect triple or pea comb of the Brahma. I endeavoured for several years successively to produce, by all manner of crossings, a Brahma, and although I managed to select from the results some fine specimens very nearly approaching the required type, yet the total absence of the triple comb, together with other points, led me to give up further attempts as hopeless, as I am persuaded we cannot produce the true and perfect triple comb with any variety we have knowledge of. The great scarcity of birds with perfect combs should induce judges to give way in some other and less characteristic points; for instance, I would overlook a poorly-feathered shank, or a wing not barred in the Dark variety, or a leggy bird proportionately heavy. Either of these points I would willingly sacrifice to a perfect-combed bird of fair average merit.—F. C.

HATCHING BY AN INCUBATOR.

The following are replies to the questions put by "Tudor," page 238.

1. Chickens hatched in the *dry* heat of an incubator would not be equal to those hatched under a hen. The incubator is imperfect if provision is not made for the production of a moist temperature. Chickens hatched in a dry temperature will never be so strong as those hatched with moisture, besides which numbers of them will, at maturity, die in the shell. An incubator I had, which was imperfect in this respect, I remedied by keeping in the egg-drawer several pieces of moistened sponge.

2. Chickens hatched artificially, provided a moist atmosphere is maintained, will, without doubt, be as strong in constitution and as sound in feather as those hatched by natural means. In the rearing without a hen there is a great advantage, the chicks thriving very much better, owing to their eating more, and becoming in a very short time independent.

3. Artificial hatching will not in any way interfere with correct colour of feather.—E. A. S.

WIGTON POULTRY AND PIGEON SHOW.

Although from the fact of this meeting being held at the same time as the Accrington Show (April 3rd—5th), the number of entries was not so great as usual, the quality of the birds exhibited was praiseworthy, and the general management all that could be desired. The district around Wigton has long been noted for the excellence of its *Game* fowls, and the specimens exhibited by local breeders fully maintained its high repute, although, as the event proved, the two cups given respectively for the best Game cock and best Game cockerel, the competition for which was open to all comers, were both secured by Mr. James Fletcher, of Stoneclough, near Manchester. It is very rarely indeed that two such extraordinarily perfect specimens are shown at the same time by one individual. They were Black-breasted Reds, true as could be wished for as to colour, and their condition such as reflected great credit on the feeder. These two beautiful birds were to the majority of visitors the chief attraction of the Show. Some remarkably good Brown Reds were also shown by local amateurs. The *Spanish* and *Dorkings* were both good, as were the *Cochin-Chinas*. Of *Hamburghs*, the Spangled were decidedly superior to the Pencilled. Strange to say, the class for Any other variety of fowls could only boast of a single entry, and that was for Dark Brahmas. Some very good Black *Bantams* and Silver-laced Sebrights were also shown.

In the class for Any other variety of *Ducks*, a pair of Shell Ducks was exhibited by Mr. Armstrong, of Aikhead, in remarkably good condition. This is, perhaps, in no slight degree attributable to the extraordinary fact that these lovely birds enjoy, as the owner informs us, almost unrestricted liberty, though pinioned. The drake has now been in the owner's possession for seven or eight years, and goes almost daily down to the seacoast to feed and wash; but sometimes it has absented itself for days together, and in one instance for so long a period as three weeks, yet it returned with the same willingness and freedom as before, much to the satisfaction of its proprietor. Mr. Harrison, of Hull, exhibited a pair of capital Mandarins in this class.

In the *Pigeon* classes were to be found some first-rate Carriers, Ice Pigeons, Owls, Hyacinths, and Turbits.

Wigton is noted for its show of Eggs, as very liberal prizes are offered both for Ducks' and for hens' eggs. They are exhibited in dishes containing a dozen each, and a very severe competition ensued. The twelve largest hens' eggs weighed 2½ lbs., and the largest dozen Ducks' eggs weighed 3 lbs. 5 ozs. The Arbitrator very properly excluded "double-yolked" eggs from competition, as being, unquestionably, malformations; and his discrimination in the first selection of such eggs was openly tested in the presence of the Committee, two dishes of hens' eggs and one of Ducks' eggs being disqualified on this account only. Three eggs having been chosen, a small aperture was made on one side of each of these eggs, fully exposing the double yolk to all visitors who might inspect them during the time the Show remained open; in all three cases the eggs proved exactly as the Arbitrator had predicted.

Game (Black-breasted and other Reds).—First, J. Banow, jun., Bradley Field. Second, T. Manduell, Aikhead.

Game (White and Piled).—First, J. Brough, Carlisle. Second, W. J. Mellor, Colwick Rectory, Nottingham.

Game.—First, T. Dyson, Halifax. Second, J. Brough.

Game (Any colour).—*Pullets.*—First, E. Aykroyd, Bradford. Second, W. J. Mellor.

Spanish.—First, J. Thresh, Bradford. Second, J. H. Wilson, St. Bees.

Dorking.—First, J. H. Wilson. Second and Highly Commended, Messrs. Gunson & Jefferson, Whitehaven.

Cochin-China (Any variety).—First, Messrs. Gunson & Jefferson (Buff). Second, Miss Aglionby, Esthwaite Lodge (Partridge). Highly Commended, Miss Aglionby (Buff); Gunson & Jefferson (Buff).

Hamburghs (Golden-spangled).—First, J. H. Wilson. Second, R. Dickson, Selkirk. Highly Commended, S. & R. Ashton, Mottram, Cheshire. Commended, Messrs. Bowman & Fearon, Whitehaven; S. H. Stott, Quarry Hill, Rochdale.

Hamburghs (Silver-spangled).—First, J. Brough, Carlisle. Second, S. E. Noble, Strickland Gate, Kendal.

Hamburghs (Gold and Silver-spangled).—First, Messrs. Bowman and Fearon (Silver). Second, R. Burrows, Longtown (Golden).

Any other Variety.—Prize, Messrs. Bowman & Fearon (Dark Brahma Pootra).

Game Bantams (Black-breasted and other Reds).—First, W. Mahon, Castle Gate, Jedburgh. Second, H. Snowden, Great Horton, Bradford. Highly Commended, M. Taylor, jun., Penrith (Black-breasted); D. Ashworth, Blackledge, Halifax.

Game Bantams (Any other colour).—First, W. Mahon (Duckwing). Second, Miss Aglionby (Piled). Highly Commended, J. Sword, Jedburgh (Duckwing); G. McMillan, Jedburgh.

Bantams (Any other variety).—First, H. Snowden (Blacks). Second, T. C. Harrison, Hull (Laced). Commended, S. & R. Ashton (Silver-laced).

Ducks (Aylesbury).—First, Messrs. Bowman & Fearon. Second, E. Leech, Rochdale. Highly Commended, J. S. Fair, Gilliestoogues, Jedburgh.

Ducks (Rouen).—First, E. Leech. Second, Messrs. Gunson & Jefferson. Highly Commended, S. H. Stott; M. Redhead, Kendal.

Ducks (Any other variety).—First, J. M. Armstrong, Aikhead (Shell Ducks). Second, T. C. Harrison (Mandarins). Highly Commended, R. Beaty, Bleunerhasset (Muscovy).

PIGEONS.

Carriers.—First, H. Yardley, Birmingham. Second, J. & W. Towerson. Egremont.

Tumblers.—First, A. Parry, Rochdale. Second, H. Yardley. Highly Commended, R. Thompson, Mercsdale Hall.

Pouters.—Prize, H. Yardley.

Fantails.—First, H. Yardley. Second, W. Gate, Wigton.

Jacobins.—First, J. & W. Towerson. Second, R. Thompson. Highly Commended, H. Yardley.

Nuns.—First, R. Davidson, Jedburgh. Second, W. Stordy, Thrustonfield. Commended, H. Yardley.

Barbs.—First, H. Yardley. Second, R. Thompson.

Turbits.—First, E. G. Jones, Parton. Second, R. Thompson. Highly Commended, J. W. C. Dugdale; H. Yardley; J. & W. Towerson. Commended, R. Davidson.

Owls.—First, J. Fielding, jun. Second, J. & W. Towerson. Highly Commended, J. Fielding, jun.; J. W. C. Dugdale. Commended, H. Yardley.

Any other Variety.—First and Second, H. Yardley (Ice Pigeons, and Spots). Highly Commended, J. W. C. Dugdale (Red Magpies); J. & W. Towerson (Blue Swallows).

Selling Class (Any variety).—First, H. Yardley (Hyacinths). Second, S. & R. Ashton (Black Carriers). Commended, J. W. C. Dugdale (Red Barbs).

EXTRA PRIZES.

Game.—*Cock.*—First and Cup, J. Fletcher, Stoneclough. Second and County, J. Brough. Third, W. J. Mellor. Commended, W. Boyes, Beverley; J. H. Wilson; J. Blough. *Cockerel.*—First and Cup, J. Fletcher. Second, J. Banow, jun. Third, J. H. Wilson. Highly Commended, J. Brough; D. Gellatly, Meigle.

Game (County only).—*Cock.*—First, J. Brough. Second, T. Robinson, Wigton. Highly Commended, J. Brough. *Cockerel.*—First, J. H. Wilson. Second, J. Brough. Highly Commended, J. Gibson, Whinnow, near Wigton.

Selling Class.—First, J. H. Wilson (Spanish). Second, R. Burrows, Longtown (Golden-pencilled Hamburghs). Third, M. Redhead (Silver-spangled Hamburghs).

Edward Hewitt, Esq., of Sparkbrook, near Birmingham, officiated as Judge.

ACCRINGTON POULTRY SHOW.

This took place on the 4th and 5th inst. The following are the prizes awarded :—

Game Cock (Any colour).—First and Second, C. W. Brierley, Middleton. Third, J. Foulds, Burnley. Highly Commended, R. Scirminger, Lutterworth; C. W. Brierley. Commended, S. Matthews, Stowmarket; C. W. Brierley. *Within four miles of Accrington.*—First, G. Furness, Woodnook. Second, T. Sharples. Third, R. Bateson, Accrington.

Game (Black or Brown Reds).—First, R. Scirminger. Second, A. Akroyd, Bradford. Third, C. W. Brierley.

Game (Any other variety).—First, C. W. Brierley. Second, T. Dyson, Halifax (Duckwing). Third, R. Scirminger.

Dorking (Any colour).—First, W. Moorhouse, Read Hall, Read (Grey). Second, H. Beldon, Goitstock, Bingley. Third, W. Harvey, Sheffield (Coloured). Highly Commended, D. Parsons, Preston; T. Rogers, St. Helens; W. Parr, Patricroft, Manchester. Commended, T. Briden, Earby, near Skipton.

Cochin-China (Buff or Cinnamon).—First and Third, W. A. Taylor, Manchester. Second, C. W. Brierley. Highly Commended, H. Belden. Commended, J. H. Davies, Birmingham; C. W. Brierley.

Cochin-China (Any other variety).—First, J. Bury, Eccles (Partridge). Second, T. Bott, Bury (Partridge Cochins). Third, H. Crossley, Broomfield, Halifax (Partridge). Highly Commended, C. W. Brierley (Partridge Cochins); Rev. F. Taylor, Kirby Lonsdale (White). Commended, C. W. Brierley (Partridge Cochins); T. Bott (Partridge Cochins).

Spanish (Black).—First, J. Thresh, Bradford. Second, H. Beldon. Third, Miss E. Beldon. Highly Commended, J. Merchant, Halifax; Hon. — Douglas Pennant, Penrhyn Castle, Bangor.

Brahma Pootra (Any colour).—First, H. Lacy, Hebden Bridge. Second, W. Hargreaves, Bacup. Third, T. Pomfret, Hoghton Lane (Dark Brahmas). Highly Commended, Mrs. T. Hargreaves, Berkshire (Dark); M. Brooksbank, Manchester; T. Pomfret (Dark Brahmas).

Hamburgh (Golden-pencilled).—First, S. Smith, Northowram, Halifax. Second and Third, T. Wrigley, jun., Tonge, Middleton.

Hamburgh (Silver-pencilled).—First, H. Pickles, jun., Earby, near Skipton. Second, H. Beldon. Highly Commended, E. Hindle, Accrington; J. Platt, Dean. Commended, W. M. Mann, Kendal, Westmoreland; H. Smith, Morton Banks, Keighley; W. Lawrenson, Eaglescliffe, Yarm.

Hamburgh (Golden-spangled).—Second, H. Beldon. Third, W. Driver, Keighley. Highly Commended, T. Walker, Denton, near Manchester. Commended, H. Pickles, jun.

Hamburgh (Silver-spangled).—Cup and First, A. K. Wood, King's Mill, near Derby. Second, J. Smalley. Third, H. Beldon. Highly Commended, Miss E. Beldon; J. Fielding, Rossendale; J. A. Taylor, Manchester. Commended, E. Collinge, Boarshaw Clough, Middleton; J. Fielding.

Poland (Any colour).—First, H. Beldon. Second, S. Farrington, Chatmoss, near Manchester (White-crested Polands). Third, Miss E. Beldon. Highly Commended, C. W. Brierley; W. Harvey (Golden Polands).

Any other Variety.—First, J. Munn, Fern Hill, near Stacksteads (Black Hamburghs). Second, R. Loft, Woodmansey, Beverley (White Sultans). Third, Col. Stuart Wortley, Grove End, London (Crève Cœurs). Highly Commended, C. Sedgwick, Ryddlesden Hall (Black Hamburghs); Miss E. A. Whittaker, Hawkshead, Windermere (Cuckoo). Commended, Mrs. Whitaker, Vicarage, Whalley (Creve Cœur).

Selling Class (Any variety not above 20s. per Pen).—First, J. Thompson, Bingley. Second, Miss E. Beldon. Third, Hon. — Douglas Pennant. Highly Commended, G. Furness (Black East Indian).

Game Bantam Cock (Any colour).—First and Third, R. Scirminger. Second, C. W. Brierley. Highly Commended, C. W. Brierley; F. J. Astbury, Prestwich, Manchester; J. Crossland, jun., Wakefield (Black Red).

Game Bantam Cock (Within four miles of Accrington).—First, Messrs. W. & H. Buckley, Accrington. Second, G. Birtwistle, Haslingden. Third, H. Smalley, Stanhill, Oswaldtwistle (Black Red).

Game Bantam (Any colour).—First, J. Rhodes, Thornes, Wakefield. (Black Red). Second, J. Haworth, Clough End, near Haslingden (Brown Red). Third, J. H. Davies (Black Red).

Bantams (Any other variety).—First, W. A. Taylor (Black). Second, Miss E. Beldon. Third, T. C. Harrison, Beverley Road, Hull.

Turkeys.—First, E. Leech, Rochdale. Second, Rev. W. J. Mellor, Colwick Rectory, Notts. Highly Commended, Mrs. A. Guy, Eaton, Grantham, Cambridge; S. H. Stott, Quarry Hill, Rochdale (Cambridge Turkeys). Commended, W. Harvey.

Geese.—First, E. Leech. Second, J. Cooper, Rawtenstall. Highly Commended, J. Hubbersty, Longridge; T. Houlker, Revidge, Blackburn; S. H. Stott.

Ducks (Aylesbury).—First, Mrs. M. Seamons, Aylesbury, Bucks. Second, E. Leech.

Ducks (Rouen).—First, E. Leech. Second, T. Bett, Bury.

Ducks (Any other variety).—First, T. C. Harrison. Second, C. W. Brierley. Highly Commended, W. Harvey; T. C. Harrison. Commended, D. Parsons, Preston (Brown Call); H. Beldon (Call.)

PIGEONS.

Carriers.—First, E. E. M. Royds, Greenhill, Rochdale (Black). Second and Highly Commended, J. Hawley, Bingley, Yorkshire (Black).

Tumblers.—First, J. Hawley. Second, J. Fielding, Rochdale. Highly Commended, W. J. Corbridge, Blackburn (Black Mottled); H. Yardley, Birmingham; J. Hawley. Commended, T. Kenyon, Accrington (Black Mottled).

Barbs.—First, A. Dove, York (Yellow). Second, J. Bromiley, Tong Moor, near Bolton (Black).

Owls.—First and Second, J. Fielding. Highly Commended, W. P. Wilding, Mountford, near Burnley (White).

Pouters or Choppers.—First, H. Yardley. Second and Highly Commended, E. E. M. Royds.

Fantails.—First, A. Parry, Rochdale (Blue). Second, T. H. Hawley. Highly Commended, H. Yardley; A. Parry, Rochdale (White).

Turbits.—First, J. Thompson. Second, L. Glassey, Rochdale.

Dragons.—First, A. Parry. Second, A. Lowe, Over Hulton, near Bolton.

Trumpeters.—Prize, J. Thompson.

Any other Variety.—First, F. Wait, Sparkbrook, Birmingham (German Toy). Second, W. J. Corbridge, Blackburn (Red Jacobins). Commended, J. H. Hawley.

Pigeons of any Variety, Within four miles of Accrington.—First and Second, T. Kenyon, Accrington.

Judges.—*Poultry and Pigeons:* Mr. Richard Teehay, Fulwood, Preston; Mr. W. B. Tegetmeier, Muswell Hill, London.

NEW BOOK.

Pigeons, their Structure, Habits, and Varieties. By W. B. Tegetmeier and Harrison Weir.

The first part of this work, under the title above given, and not under that by which it has for several weeks been advertised—viz., "The Pigeon Book," appeared on the 1st of this month. This alteration of title is well, as Mr. Brent's work is known to all fanciers throughout Great Britain and Ireland as "The Pigeon Book."

I confess to a little disappointment with this first part, still it is but Part I.; yet there is a proverb, "Well begun is half done." I have for years been an admirer of the fruits of Mr. Harrison Weir's pencil, and am still in the various periodicals which each month find their way into my house; but surely he has not here done himself nor the Pigeons full justice. There are four pictures, a pair of Turbits and a pair of Jacobins on one leaf, and a pair of Nuns and a pair of Swallows on another. Some of these pictures have the appearance of having been sketched from caged birds, indeed as if on the last day of a long show. The pair of Turbits are the best, but somehow one does not obtain any notion of the exquisite softness of feather possessed by the living birds. Besides, why has Mr. Harrison Weir represented Turbits with turned crowns? The old English birds never had them; they are but German innovations, and are therefore disliked by the best authorities. Indeed, I think the turned or point crown spoils the head of the Turbit as much as it does that of the Barb. Next come a pair of Jacobins—birds full of misery, apparently just washed, and the weather cold. Their eyes are looking round the corner, and I am sure they would like to have their hoods pulled on further, indeed a more moping pair of birds I never saw; next a pair of Nuns, the lower bird crouching uncomfortably. Lastly there is a pair of "Swallows," and why Swallows? I hoped in this new work on Pigeons this bird would be called "The Tern," or at any rate "The Sea Swallow." The Magpie Pigeon comes up to its name, but the word "Swallow" conveys a false idea. These birds, too, have turn-crowns, to which individually I object, as they cause them less to resemble that bird from which they take their name. Mr. Harrison Weir's pencil has for years given me much pleasure; and I trust that in the future parts of this work we shall have Pigeons not only from life, but full of life, and therefore more pleasing.

As to Mr. Tegetmeier's part, there are twenty pages in all. Chapter I., on "The Structure and General Character of Pigeons," from its subject must almost necessarily be dull. There is, however, an interesting quotation two pages long from the Duke of Argyll's "Reign of Law," and another of a page and a half long from John Hunter. Chapter II., "The Rock Dove," is made up entirely of quotations. In the first place there is an extract from "Macgillivray's British Birds," six pages long; then immediately there follows one from Mr. Henry D. Graham, two pages and a half in length.

When Mr. Tegetmeier gets fairly into his subject I hope we shall not only have what is true, but also what is new.—Wiltshire Rector.

Bagster's Process of Melting Honeycombs.—The combs are placed in a conical earthen vessel filled with a mixture of

1 oz. of nitric acid to a quart of water. This is set over an open fire and stirred till the combs are completely melted, when it is removed from the fire and allowed to cool gradually. The product is divided into three layers, the upper one pure wax, the lowest chiefly impurities, and the middle containing sufficient wax to be added to the next melting. A marketable wax is thus obtained at a single operation, without straining or pressing.—(*American Bee Journal.*)

PROPAGATING LIGURIANS.

The first step towards the multiplication of Ligurians is, of course, the obtaining a stock of bees with a pure queen; and, as the purity of the original queen is of such essential importance that unless it is secure all future proceedings can only end in disappointment, no precaution should be neglected in endeavouring to attain this end. I should, therefore, advise no one to purchase a Ligurian stock of which the vendor will not guarantee the purity of the queen, whilst it is of at least equal importance to buy only from those whose known character and standing among apiarians are such as to give weight to their guarantee.

This indispensable preliminary being secured, most persons will probably expect to be at once enabled to propagate the pure Italian race—at least, I know that I did so, and it took some time, and a considerable amount of rather unpalatable experience to undeceive me. It is true, that if the Ligurian stock be so exceptionally strong in early spring as to breed drones well in advance of every black stock within a radius of from three to four miles, and young queens can be reared before any black drones are produced, the queens will stand a good chance of obtaining pure impregnation. Although, singularly enough, I was so fortunate as to attain this result with the first queen I ever reared, subsequent experience has satisfied me that success in the first attempt with only one Italian colony is so rare, that it is far better to devote the first season to furnishing every stock in the apiary with a Ligurian queen, multiplying the queens at the same time as far as may be deemed desirable, but paying little or no heed to the character of their impregnation. For reasons which need not be entered upon here, but which have been already specified by me in discussing the subject of parthenogenesis in the honey bee, all these queens, although they may, and most of them probably will, breed a mixed worker progeny, will in the next and succeeding years breed only pure Italian drones, by the multitude of which the chances of a true impregnation will in the ensuing season be so much increased that the purity of the majority of young queens of the second year is not improbable; whilst if care be taken to keep all the stocks well up to the mark, success in the case of early-bred queens becomes nearly certain. During this second season, therefore, all doubtful queens of the first year should be weeded out and replaced by those of the current year.

Queens may also be bred in the autumn, and when all black drones have disappeared can scarcely fail of true impregnation, if a sufficient number of Italian drones can be preserved and the weather be warm enough.* For this purpose the usual drone massacre may be deferred almost indefinitely in one or more stocks by removing the queens. It is in this case necessary also to destroy or remove any young princesses that may be raised, since not only will all drones be speedily destroyed in the event of a princess becoming fecundated, but the workers sometimes become so impatient of their presence under such circumstances, that a partial, or possibly an entire, massacre may take place even before the juvenile monarch has been able to avail herself of their services.

I should advise every one who intends propagating Ligurians to provide himself with several nucleus-boxes, fitted for the accommodation of "nuclei," as small artificial swarms have been not inaptly designated. Those which I use are made of three-quarter-inch wood, 14½ inches long, by 6½ inches wide and 9 inches deep, which will accommodate four frames, although in practice I seldom put more than three combs in each.

In order to stock a nucleus-box and raise a queen therein, I commence during the middle of a fine day by looking over the combs of a pure Italian stock until I find the queen on one of them. This comb, with the queen, is then put carefully on one side, so that her majesty may not be jeopardised or interfered with in any way, whilst another comb is selected containing worker brood in all stages, from the egg to the sealed nymph, which, with the adhering bees, is put in the nucleus-box, into which the bees from two other combs are rapidly swept with a strong feather. Two spare combs being placed one on either side of the brood-comb, the bees must be confined by the top of the box being covered by perforated zinc instead of the crown-board, whilst the entrance is closed by the same material, and the nucleus should then be conveyed to a dark cellar, there to remain until evening. After dusk it must be placed in the position it is intended to occupy in the apiary, the bees set at liberty,* the crown-board put in its place, and all made snug for the night. A great rush usually ensues, but few will take wing in the dark; and although most of the involuntary truants may return to their home in the morning, so many young bees that have never taken flight, and consequently know not their way back, must perforce remain that the brood will probably be well covered and royal cells will appear in due course. All this must not, however, be left to chance; but an examination of the nucleus should be made in the forenoon of the third day, when, if the population be too scanty, it must be recruited by brushing into it the bees from one or more combs of the parent stock, the same preliminary precautions being of course taken to insure the safety of the queen.

If the Italian stock be strong, and the vacancy can be at once supplied by a comb of black worker brood, the abstraction of bees will scarcely be missed, and may be repeated, and a nucleus stocked, if required, nearly every other day in the height of the season; but every comb of black brood should be marked with the day of the month on which it was inserted, and not employed for breeding Italian queens, until—say twelve days afterwards. If combs of black worker brood are unattainable, the place of those abstracted should be occupied by empty worker combs, which will rapidly be filled with eggs; but if no worker comb be attainable, the remaining combs must be brought together and the vacancy left on one side.

Cases may, of course, arise in which the pure Italian stock is so exceptionally weak as not to bear the loss of either brood-combs or bees; but even in such instances proceedings need not be delayed long after breeding has fairly commenced, but may be so conducted as to add to instead of diminishing the strength of the colony. With this view, every bee should be swept off the selected comb, and its place being at once supplied by a comb of black brood in a more advanced stage, a positive advantage will be at once secured, whilst the requisite population for the nucleus-box may be obtained by brushing into it the bees from three combs lifted out of a black stock for the purpose, care being taken that the queen is not among them.

These little artificial swarms will frequently raise many royal cells. On the ninth or tenth day, all but two of these may be extracted and given to more recently-formed nuclei, which will thereby gain a considerable advantage in point of time. They should be cut out with a triangular bit of comb attached (apex downwards), and inserted in a similarly-shaped hole cut in the brood-comb, which, in this case, may be taken from either a common or the Ligurian colony, the latter being, of course, preferable as a *dernier ressort* in the event of the failure of the inserted royal cells. In all these operations the greatest care should be taken to avoid bruising or chilling the royal embryos, and for this reason they should be conducted as rapidly as possible in the middle of a warm day. Although it might at first sight appear that, by inserting sealed royal cells in the brood-combs at the time of stocking nuclei, trouble would be saved and subsequent operations rendered unnecessary, experience proves that it is better to delay the insertion until a day or two afterwards, when such cells will generally be fixed and accepted by the bees; whereas, if given to them at the time of the first formation of the swarm, they are very apt to be at once torn open and destroyed.

Dzierzon, the great German apiarian, says, "It is an advantage, although not absolutely essential, to add a brood-comb to every artificial swarm or stock in which a young queen has been hatched, since, on account of the increased warmth and activity which will thus be produced in the hive, the juvenile princess will sooner mature for impregnation, will take her wedding-flights earlier, and from the bees being induced to play out in greater numbers she will be enabled to find her hive on her return with greater certainty. Whether young Italian queens are fertilised by Italian drones, especially in the height

* Dzierzon states that a temperature of above 70° is required.

* This is important, as great loss of life often takes place if the liberation be delayed until the next morning.

of summer when both drones and queens fly far from home, must be left to chance. The bee-keeper may, however, do something to further true impregnation by encouraging those stocks which have the most Italian drones, as well as those with young queens, to a simultaneous flight rather early in the day, whilst other drones remain quietly in their hives, which may be done by giving them liquid food either in the ordinary way or by injecting it into the hive."

Having thus endeavoured to convey information on every point that has occurred to me in connection with the multiplication of the Italian variety of honey bee, and having thereby replied to the queries of numerous correspondents, I need only add that I shall be most happy to supply any deficiency that may be pointed out.—A Devonshire Bee-keeper.

PREVENTING SWARMING.

Is there any practicable and easy method of preventing bees from swarming? Two years ago I began bee-keeping for profit, and had a house made capable of holding three stock hives, and two supers on each if requisite; the boxes are of wood, with two glass sides in each, so that I may be able to watch the movements of the bees; the flight-board of the stock hives is all that can be seen on the outside of the house, which is under lock and key. After all my care and attention I find myself up to the present time debtor to cash.

The difficulty which I cannot master is this, when I see my bees likely to swarm I place a super on in hopes of retaining the workers by increase of room, but to no purpose, for it appears that when all is ready off they go. I still leave the super on, hoping that as a further increase takes place the super may be filled with honey, but no, they seem to prefer taking themselves off with their new sovereign, and the super, the access to which is through three holes, each 2 inches in diameter, remains empty; thus the season passes over, and leaves me minus of honey. Some will perhaps say you must destroy the young queens as they are hatched, and the evil will be remedied. That is easier said than done, especially in a stock hive. The queen may be captured while swarming, or after the swarm is taken, and the bees will return to the hive only to wait further orders; but all that is attended with danger and difficulty. But when they fly off, what then?—catch them if I can I suppose. Well, that is the trouble I want to prevent.

At the end of last year I successfully applied chloroform to two small swarms, and joined them with two others; they are now well and strong. I did not find either of the queens.—A Novice.

[No system of management can be depended upon for the absolute prevention of swarming. Sufficient room should be given in good time, and the temperature of the hives carefully attended to whilst the supers are filling, recourse being had to increased shade and ventilation immediately the bees show signs of being oppressed by heat. In spite of all these precautions swarms may issue, and if the combs be fixtures in the hive we deem it better to accept them without further demur. If, however, the combs are moveable, the swarm should be temporarily hived in a common skep; and the young queen, if any, being removed, and all royal cells excised (a task which the deserted condition of the stock hive will render sufficiently easy), the swarm may be returned with every prospect of no further issue taking place until the super be complete, even if the intention to swarm be not altogether frustrated.]

AMERICAN BEE PLANT—Cleome integrifolia.

This plant has been cultivated to some extent in this neighbourhood for several years past, and proves one of the best and probably the very best honey-producing plant known. It was introduced by the writer about the year 1860 as a new annual flowering plant, from the Rocky Mountain region, but its great value was not at that time known and was not discovered until a year or two after, when the writer was surprised to see the plant covered with bees, while other flowers in the immediate neighbourhood were quite neglected. The next year a much larger quantity of this plant was grown, and it was found that the honey stored in boxes at the time that this plant was in bloom was of a much finer quality than any other. Every succeeding year of its cultivation, confirms this, and I find that while this plant is in bloom nearly all other flowers are discarded; even the Buckwheat, which every one knows is a great favourite with the industrious little fellows, is quite deserted. The honey stored from this plant is positively the finest both to the eye and the palate, of any that I ever saw.

The plant is of easy culture and looks well in the flower garden. It is a strong grower, and much branched like the common Mustard plant, though its flowers are a bright purple, and are produced from midsummer until frost destroys it in autumn.

It will grow on any soil, though a rich one suits it best, and may be sown in drills, or broadcast if the ground is clean. Autumn is the best time for sowing as it comes into bloom sooner. It has already acquired the local name of "Bee Plant," in this vicinity (Chicago) and as it is indigenous I propose that we call it the Great American Bee Plant.—H. A. Terry.—(*Prairie Farmer.*)

OUR LETTER BOX.

Hens Eating their Eggs (*B. B.*).—There is no remedy. The remaining eggs should be put under another hen, and the culprit should become soup-meat.

Spanish Cockerel (*A. H. D.*).—The moping and blistered face intimate he has suffered from the long winter, and is only now recovering. While the ground was covered with snow, we did not see our fowls; they kept in-doors and in shelter. Now, when the weather is finer, we ourselves feel more cheerful, and expect to see everything flourishing. Give him bread steeped in strong ale, some lettuce if you have it. If he has no grass, give him some sods, and let him have fresh earth every day. Let him have ground food, no whole corn.

Poultry Runs (*J. S.*).—Cover the surface 3 or 4 inches deep with road drift. Have a heap of ashes and limy rubbish under cover, so that the fowls can have a bath and the raw material of their egg-shells whenever they wish. Ground oats and boiled potatoes in equal proportions form a good diet for all fowls. It would be well to let each variety have a few hours' run in the field daily, rather than one whole day and then miss two.

Fowls Eating each other's Feathers (*An Amateur Poultry Breeder*).—The facts you detail are all indicative of internal irritation in the fowls. Give them no whole corn. Feed chiefly on barleymeal and boiled potatoes; give as much of lettuce leaves as you can; and let there be a heap of dry ashes mixed with some limy rubbish under cover that the fowls can have access to all times. Do not omit the limy rubbish.

White Dorkings (*J. Steven*).—We cannot interfere under the circumstances. Give notice for the post-office order not to be paid, and wait to see if legal proceedings are adopted.

Caponising (*C. E. G.*).—We know of no work upon this cruel and needless practice.

Desirable Fowls (*R. J. H.*).—As eggs, chickens, and good appearance are required, we think you had better adopt Dorkings. They are average layers, good sitters and mothers, and beyond contradiction the best birds for the table. It is necessary they should have a run, and you can give it to them. If you object to this breed you can have Cochins, Brahmas, or Game. We know no others that will suit you so well as one of these, because they each possess all the qualities, while many of the best layers do not sit.

Poultry (*J. R. Beyton*).—We should keep Brahma Pootras in preference to Houdans if having your object in view; but you must not expect to obtain high prices until your stock is noted for prizetaking. Chickens hatched in April will not be old enough for exhibition in July unless very precocious.

Asthma in Canaries (*A Subscriber*).—We should prefer not breeding from a Canary liable to the disease; but if he be mated with a perfectly healthy hen the risk of an asthmatical progeny will be very small.

Aviary.—There was a misprint in our Journal of Thursday last in answer to the inquiries of "Changeable." We said that in an aviary "2 yards square and 1 yard high" fourteen kinds could be kept. It should be 2 yards square and 3 yards high. An aviary of the height we mentioned would not contain fourteen birds for breeding.

Hives (*C. A. Dunn*).—Apply to Messrs. Neighbour & Sons, Regent Street, or to Mr. Pettitt, Hive Manufacturer, Dover.

Flowers for Bees (*Index*).—You may sow Mignonette, Borage, and Melilotus leucantha.

Artificial Swarms—Production of Queens (*J. H.*).—When making an artificial swarm by putting a hive containing a Ligurian brood-comb in the place of a stock of black bees, the Ligurian bees should remain on the comb. Our earliest successful queen was hatched on the 29th of April. Putting a royal cell in a cage when presenting it to a queenless stock, is not only quite unnecessary but is absolutely useless.

Ventilating Hives—Nadirs (*Suffolk Bee-keeper*).—In ventilating hives kept in a bee-house, it is not essential that the air admitted should come from the exterior of the house. We should much prefer supering to any system of nadirs.

Ligurian Bees (*Young Soldier*).—See the observations of "A Devonshire Bee-keeper" in our Journal to-day.

POULTRY MARKET.—April 10.

Good young poultry is very scarce, and meets a ready sale at large prices. Inferior qualities are not in demand, and find a heavy sale.

From observations taken near London during the last forty years, the average day temperature of the week is 59.2°; and its night temperature 36.0°. The greatest heat was 77°, on the 19th, 1854; and the lowest cold 18°, on the 24th, 1854. The greatest fall of rain was 0.60 inch.

CULTURE OF TRICOLOR PELARGONIUMS.

THE present is a good time to propagate and repot this most beautiful class of bedding plants.

Mr. Pearson, of Chilwell, gave some hints on the culture of Variegated Pelargoniums at page 343 of the last volume of this Journal; if he will use the turf soil, such as he recommended in the Number for January 24th of the present year for the growth of Camellias and the formation of Vine borders, he will find that the plants will root very much more freely in it than in the mixture which he recommends. I can fully indorse all that Mr. Pearson has said in favour of using green or partially decayed sods for the cultivation of the Camellia, and, indeed, for almost any kind of plant that will grow in light sandy loam. To keep soil in large stacks for any length of time is a mistake. Before cutting up the sods I have the grass shorn off as closely as possible; the sods are then cut in pieces about 1 foot long, 9 inches wide, and 1½ or 2 inches thick; they are stacked in narrow ridges, and are only allowed to remain stacked long enough to kill a portion of the grass. They are then pulled to pieces, and used at once. For all purposes turf is decidedly much better pulled to pieces than chopped.

I have never had my Tricolor and other Pelargoniums rooting so freely and growing so luxuriantly as they are this season; many of them are now in 8 and 12-inch pots: a description of my mode of treating them may therefore prove interesting to some of the readers of "our Journal." In the first place, the soil which I find most suitable consists of fresh sods cut from a light sandy loam, pulled to pieces, as recommended by Mr. Pearson for Camellias, adding to every barrowful of sods a 32-sized potful of bone-dust. This is the only manure which I mix with the soil, and I find that in it the plants root much more freely than when other manures are used. If the soil is naturally sandy, no sand is mixed with it. After the plants have well filled their pots with roots they are supplied two or three times weekly with manure water in a clear state.

Most of my plants were shaken out in the beginning of January, and potted in small pots in nothing but the sods, no bone-dust or manure of any kind being used. By the end of January they had commenced rooting very freely, and as soon as the roots had reached the sides of the pots the plants were shifted into others of larger size, adding at each shift about 2 inches of soil to the ball, and many of those which were in 60 and 48-sized pots in the last week in January are now in 8, 10, and 12-inch pots. The plants received their last shift only a fortnight ago, and their roots have now reached the sides of the pots, and are rapidly creeping round the ball. Every time the plants were shifted great care was taken to have both the new soil and that in which they were growing in just the same state of moisture, and as nearly as possible of the same temperature. I may also observe that the plants did not require water till the roots had reached the sides of the pots, and to paying particular attention to this, and using proper care in watering newly-potted plants, I attribute a large portion of my success.

The plants are grown in a light house, and near the glass. Before potting see that the pots are clean, especially on the inside. This is a point which should be carefully attended to: for if you put a plant into a dirty pot, when the time comes for shifting it again, on turning it out of the pot it is sure to leave many of its most healthy roots adhering to the old soil. Great care is also necessary in taking the drainage away from the balls not to break or disturb the roots, and after the drainage has been carefully put into the pot, and a portion of soil placed upon it, before the plant is set in the pot, make a little hillock in the centre with some of the most tempting bits of sod, so as to just fit into the place before occupied by the drainage; the roots that were formed around the outside of the drainage will then rest on the sides of the cone formed by the pieces of sod, and the soil can be filled in around the ball without the slightest injury to the roots. The best time to repot is when the roots have just reached the sides of the pots: the plants can then be placed in larger pots without injuring their roots, and these will more readily work into the new soil than if they were allowed to fill the pot before shifting. At the first potting, after the old soil has been shaken from the roots, hold the plant in the left hand and with the right place the soil about its roots, gently shaking the plant all the time so that the soil may be properly settled among them; the soil should not be pressed into the pot until it has been well settled by shaking the plant and tapping the pot on the bench. The same care should also be observed in subsequent pottings.

As soon as the plants have well filled their pots with roots after the last shift, they may be watered every day in hot bright weather. Now that the days are longer and frequent gleams of sunshine appear, the house is shut up early in the afternoon, and the plants have a slight dewing overhead with the syringe; this must, however, be done early, so that the foliage may become dry before night, for Tricolor Pelargoniums are very impatient of moisture on their foliage. I consider the morning the best time to water them at the roots, there is then no danger of an excessive amount of moisture during the night, when the plants should be partly at rest, and if any of them should become dry during the day a skiff from the syringe keeps them from harm till next morning. Of course none of them must be allowed to flag through want of water.

Cuttings of all the most delicate kinds of Tricolor Pelargoniums will strike very readily now in a temperature of 55° or 60°, but they must not be placed in any house where the air is charged with much moisture. If the pots in which the cuttings are inserted are partly plunged where they will have the benefit of a slight bottom heat of 45° or 50° it will cause them to strike much more rapidly, but

care must be taken not to make the soil in which the cuttings are inserted wet. Scarcely any water will be required from the time the cuttings are put in until they are rooted, if they are slightly sprinkled overhead every day, but this sprinkling should not be performed too late in the afternoon. I find the best plan is to strike the cuttings in small thumb-pots, putting one cutting in each pot. The pots should be well drained, the soil pressed in moderately firm, and the cutting should also be made firm in the pot; the best mode of doing so is to make some small hooks, and with them fasten to the soil two of the leaf-stalks of each cutting. It is also important that the base of the cutting should rest flat on the bottom of the hole made by the dibber. An average temperature of 50° or 55°, with all the air that can be given, is the most suitable for this most valuable class of plants.

Since writing the above I have been taking off cuttings from some of my new Tricolor varieties, the greater part of which I believe to be distinct from any at present in cultivation. As it may interest some to know how these beautiful varieties were obtained I will give their pedigree. Several raisers of new Pelargoniums have employed Mrs. Pollock and Sunset as the female parents, and this is the reason of many varieties being so much like the two just named. As soon as these were distributed to the public I obtained plants which were very small, and it was some time before they became strong enough to produce a truss of bloom. They were placed on a shelf in a dry airy place to bring out their colours as much as possible, and to starve them into bloom; the desired effect was soon produced, and the pollen was immediately taken from their tiny flowers and used for fertilising the blooms of Baron Ricasoli, and several of the darkest Zonal kinds amongst my own seedlings. As soon as the seeds were ripe they were sown, and the only seedling I could save from the whole batch that came up with variegated cotyledons—Beauty of Huntroyde—refused to grow, and I was not able to propagate it till last year. This season it grows very freely, and proves to be distinct from anything I have seen amongst Messrs. Henderson's extensive collection. The seeds were gathered from Baron Ricasoli, the flower of which had been fertilised with the pollen of Sunset.

From the same cross many of the seeds came up with yellow cotyledons; Beauty of Oulton was the produce of one of these. All the green seedlings from this cross were saved, and showed no sign of variegation the first year, but early in the following year I observed faint streaks of red and purple on the stems, and as the season advanced these streaks of variegation on the stems of the plants began to develope and extend, and by the end of 1865 they had covered nearly one side of the stem. Early last spring the tops were taken off, and the plants then threw out some splendid sports.

The variety named Lotty Wills is the produce of one of the green plants; this I consider a superb variety, it grows very freely, and remains true to its character. The natural size of the leaf is nearly double the size of the specimens noticed at page 233. This variety has the beautiful colouring of Sunset, but the colours are much more clearly defined; it also has a much stronger habit of growth than Sunset. The same truss of flower produced Beauty of Oulton; this fine variety took more after Baron Ricasoli, it received the yellow ground from Sunset only.

Aurora Borealis is also a sport from the same cross, and is, perhaps, the best Tricolor Pelargonium ever produced. The outline of the leaf is very handsome, the colours round the margin are very distinct, and the centre of the leaf is perfectly green, and most beautifully defined; none of the beautiful colours on the zone and margin of the leaf running into this green portion, so that the plant stands the weather much better than any other variety I have seen.

The other three varieties are from my own seedling Zonals crossed with pollen from Mrs. Pollock; the female parents had very dark zones, one of them was nearly black.

Florence is one of the best sports from this cross; it is unsurpassed for depth of colouring, has a strong vigorous habit, and is very distinct. The plant this variety sported from remained perfectly green up to the summer of 1866.

Of Fanny, the leaves are nearly scarlet when exposed to the full sun in the open air; the foliage is beautiful, circular, and of good substance. This is also a sport.

Of Northern Star, the specimens sent were very small, and not well coloured; it is, however, one of the most beautiful.

The above are a few out of a stock of several hundreds of fine varieties. This should teach those who wish to raise distinct varieties of Pelargoniums not to be too hasty in throwing away their green-leaved seedlings, but to preserve them for at least two years. I have some very promising seedlings from the double Pelargoniums that have been distributed during the last year or two; a description of these and some curious sports shall form the subject of another paper shortly.—J. Wills.

VINES AND VINE BORDERS.

My remarks on the above subject have induced many of your correspondents to join in the discussion. "A Gardener" (page 22), who "thought it was really requisite for some one of experience in the matter to make a few remarks as quickly as possible," treats us to an account of some Vines, which, having all the good things Vines are supposed to care for, acted somewhat in the way your correspondent himself would have done had he feasted for six days off a joint of meat, and found his stomach unequal to the effort of another go in on the Sunday; and so the roots of "A Gardener's" Vines, refusing the food so carefully prepared for them, bored through 6 inches of grouted brick pavement, perforated the subsoil beneath to a depth of 9 feet, and were then, when cut through, found to have a thickness equal to a man's finger! Very extraordinary roots, I admit, for Vines to make in two years; and if "A Gardener" had measured them at their base, where their diameter would have been twice as much as he found it at 12 feet 6 inches from the stem, and given us the circumference of the latter, the account of his Vines and their roots in the second year of their growth would have been complete. The Vines of "A Gardener," with their enormous roots "cribbed, cabined, and confined," in their vault-like structure, will give him good Grapes I have no doubt. They would do the same with one-tenth part of the trouble and expense he declares to be so necessary. Then why incur either the one or the other?

"G. H." (page 117), calls the system Mr. Wills advocates the "show system," and thinks I should be satisfied with a success equal to the cost incurred even if I never took a London prize. This is not a fair statement of the question under discussion. Mr. Wills wants a large supply of fine Grapes for his employer's table, and gives us a good idea of what the cost will be to obtain them. I want a still larger supply of equally fine Grapes for those who choose to buy them, and I gave a candid statement of everything I had done to grow them. I asked Mr. Wills for further details of his arrangements, and desired to know whether my Vines would have grown more if I had incurred greater expense in the planting of them. Mr. Wills is silent on the subject, and so the question of economy *versus* extravagance must remain as it is for the present.

I wish to correct the assertion of "G. H.," that in France "the Vines are cultivated on hill sides, upon terraces, which are formed by bringing down the soil at intervals, thus exposing the rock, or a rough wall built up to support the next terrace to the full sun heat." This is true only to a certain extent. The Vine crop of France, worth £30,000,000 per annum, is not so grown.

"G. H." says "'H. S.' gives us as his idea of Vine temperature the forty-fifth degree of north latitude, with a mean temperature of from 70° to 73°;" and, again, "but I should to make a true calculation, take the mean of the year as 'H. S.' does." When I said that near the forty-fifth degree of north latitude in a mean *summer* temperature of 70° to 73°, Vines grew and produced good fruit without cultivation, I merely mentioned a fact which every gardener ought to be acquainted with.

"G. H." must not think the above temperature is necessarily accompanied by an intense sun heat such as he mentions. The direct rays of the sun have less to do with the growth of plants, and the maturity of their fruits, than is generally imagined. Provided the autumn be warm and dry, there will be no perceptible difference in the fruit of the Oak, whether it be taken from one side of the tree or the other, and Blackberries will be equally large on the north side of a hedge as on the south, and just as good in flavour.

In hot countries vegetation follows the watercourses, and plants of low growth are most luxuriant where partial shade is afforded by neighbouring trees. Climbing plants, as a rule, are fond of shade and moisture, and if a climber be found in the open, it is always a miserable object, unless the rainfall has been excessive. In addition to the shade which plants and trees afford each other when growing in close proximity, the sky is always more or less obscured, and the temperature comparatively low till the leaves become fully developed. Within the

tropics rains and clouds accompany a vertical sun, and then everything starts into growth as if by enchantment. By the time the new shoots have made their terminal buds the rains are falling in other lands, and the sun, no longer vertical, sends his slanting rays from above the distant clouds to warm and dry the air, and finish the growth the rains commenced.

Mr. W. Thomson thinks my question to Mr. Wills about the styptic a very ridiculous one. The original suggestion to use it to the bottoms of Pelargonium cuttings, appeared to me and to others to be equally ridiculous. One unfortunate correspondent has lost the whole of her cuttings in her attempt to imitate Mr. Wills, and yet one would suppose the fingers of a lady were well adapted for so delicate an operation. Gentlemen seeing their gardeners exhibiting their scientific acquirements in the manner suggested by Mr. Wills, would prefer throwing both styptic and Pelargoniums to the limbo of broken pots, for its use in a garden should be an exception and not a rule.

I believe that every one who asks a question is pleased to receive a plain and candid answer. Therefore, I confess that Grapes grown in the open air in the countries I referred to, cannot compete with the best Grapes grown in hothouses in this country, either in size of bunch or berry, but in flavour they often surpass them, and if the crop were limited to a few bunches and these had the care and attention given to the produce of an English hothouse, they would lose nothing by the competition. With equal readiness I admit, that in southern Russia the thermometer does at times go up among the nineties. It does the same in this country. In the month of June, 1845, thermometers at the back of north walls in the Isle of Wight marked 92°. I have had the whole of the skin scorched from my insteps by the power of the sun in a country as far north as Scotland. Such flashes of heat prove nothing, and would be positively injurious in Europe if continued for any length of time.

I have lived on the Continent for years. I have visited French gentlemen in their country homes and know something of their establishments. I am, therefore, able to endorse nearly all Mr. Thomson has said about French hothouse Grapes. They are often inferior to the vineyard Grapes of the south. Horticulture is not encouraged in France as it is in England.

Thus far I have been able to agree with Mr. Thomson, but I deny his assertion, that the vineyards of the Rhine are subject to a higher temperature than he has recommended for hothouses. If it were true it would affect the temperature of the three summer months. The mean summer temperature of Strasburg and Heidelberg is 65°, only 1° more than that of Berlin, and barely 5° more than the mean summer temperature of Dublin.

"What may be termed a temperate climate is that most suitable for its cultivation." Such is Mr. Thomson's statement in the first page of his treatise on the Vine. Is a temperature of from 70° to 95° a temperate climate? Is a moist heat of 100°, which Mr. Thomson now declares to be advantageous to the Vine, to be found in the temperate zone? Do plants within the tropics enjoy such a *chaleur d'enfer*, as this within a few weeks from the commencement of their new growth?

I will put this question of temperature in another form. I have a span-roof house, 100 feet by 16 feet. If I were to divide this house into four compartments for the separate cultivation of plants requiring different temperatures, the compartment having the lowest temperature to be planted with Vines; the next to be filled with Oranges, Lemons, Citrons, and Olives; the third with Date Palms, Sugar Canes, and Pine Apples; and the last with Cocoa-nuts, spices, and Cacao trees —if Mr. Thomson's temperature of 70° to 95° be proper and necessary for my Vines in the first compartment, will he give me an ascending thermic scale of cultivation for my other compartments? Hamburghs do not grow in Fernando Po, nor Muscats in the Caracas.—H. S.

RIVINA LÆVIS CULTURE.

This native of the West Indies was cultivated by Philip Miller more than a century since, yet is not so well known as it deserves, for of fruit-bearing plants adapted for decorating the dinner table I would give the preference to it. The plant produces a great number of elegant drooping racemes, 4 inches in length, of beautiful scarlet berries throughout the autumn, winter, and spring months—indeed, its value cannot be overrated. A shilling packet of seed (which we had true from Messrs. Barr & Sugden), sown in April, will produce plants which will fruit well from the following autumn.

The seed readily vegetates in a Cucumber-frame; and when the plants are about an inch high they should be potted singly in thumb pots. When well established they should be shifted into 32-sized pots, in which they will fruit abundantly. In the following spring, if larger plants are required, they may be shifted into 24-sized pots, in which they will produce an immense number of fruit, which is exceedingly useful for garnishing Grapes and other fruits, and also for mixing amongst cut flowers for vases, &c. A few sprigs mixed amongst white Camellias, white Primulas, and other flowers for bouquets, give a most enchanting appearance.

The soil which the plants require is peat, with a little loam and sand, well blended together, and they may be grown either as standards, pyramids, or bushes. A warm greenhouse or stove suits them best from October till March, and in the summer months they will grow well in a cold pit or in the open air.—John Perkins, *Thornham Gardens, Suffolk.*

ORIGIN OF TRICOLOR PELARGONIUMS.

I have read the letter of your correspondent Mr. Pearson with some interest, as having, like him, been considerably amused by the contents of some of the letters which have from time to time appeared on this subject. I also hope, and I am inclined to think, that on a second thought Mr. Pearson will hardly feel inclined to set me down as a humbug, if, as far as Golden Tricolor Pelargoniums are concerned, I plead guilty to the charge of "having foreseen the probability of our dark-zoned varieties becoming tricolor, and crossed for the express purpose of producing them;" and, what is more, I certainly made no secret of my views on the subject, and should you be kind enough to give this letter a place in your columns, it will in all probability meet the eye of more than one who may recollect having heard me express those opinions, previous to the introduction of Mrs. Pollock, or any other Golden Tricolor Pelargonium.

What suggested the idea to me was simply as follows:—I had observed that by crossing the silver-margined varieties, which were not numerous at that time, with the green-leaved zoned sorts, the result was a per-centage of seedlings with silver margins, and some of them with the addition of a well-defined or pink zone, very pretty when the foliage was in a young state, but nearly disappearing as the leaves advanced in age.

Reasoning from analogy, nothing I think could be more natural than to arrive at this conclusion—viz., that as the union of a zoned with a silver-margined variety was ascertained to produce progeny having pink or red zones, and also silver margins, so the union of a zoned variety with a yellow-margined variety might reasonably be expected to produce progeny having yellow margins, and with zones of more intensity of colour. Knowing, as I did, that the mingling of brown and yellow would produce a red, on the same principle as blue and yellow will produce green, the anticipations of those results led to various experiments being tried, and their realisations are now sufficiently well known; and I believe that it is generally admitted that the introduction of this class of Pelargoniums is a consummation worthy of being wished for.

Some of my friends, I believe, give me credit for being instrumental in their production, others qualify the matter by saying that I did so "quite accidentally," and others say that I had nothing whatever to do with it, but that they produced themselves spontaneously and simultaneously.

If any one will take the trouble to carefully examine a leaf of a heavily-zoned Pelargonium he will find that the change which takes place when that leaf is induced to become variegated is not quite so wonderful as it may at first sight appear to be. The upper surface of the leaf shows, we will suppose, a well-defined zone, or horseshoe, but the under side shows no indication of a zone whatever; and if a leaf be cut into two pieces, the assistance of a magnifying glass will show that the brown colouring matter which constitutes the zone does not extend to the entire thickness of the leaf, but appears somewhat in the form of a coat of dark brown paint resting upon the green tissue of the leaf, and kept as it were in its place by the translucent epidermis which covers the upper surface. Now, when a variety of Pelargonium to which the dark zone is natural can be induced to become variegated or yellow-margined, the natural position or locality of the zone is over the very part where the undulating or irregular junction of the yellow margin and the green disc or centre of the leaf takes place: consequently whatever portion of the yellow margin

happens to lie under the brown zone will, as seen through the transparent epidermis of the upper surface of the leaf, appear quite red, the production of the brown and the yellow colouring matter; while that portion of the zone which may rest upon the green portion of the leaf retains its normal or brown colour to a certain extent, influenced, however, by a certain amount of blending resulting from the contact of the different colouring matters contained in the leaf, and giving to the entire zone, as seen through the transparent epidermis, that rich bronzy shade of colour which in many of the best varieties is so deservedly admired.

It will be observed that my remarks have all referred to what is known as the Golden Tricolor section of Pelargonium, which is essentially distinct from the Silver Tricolor; so much so that all attempts on my part to obtain a cross between the two sections, and combining the properties of both parents, have hitherto failed.

The latter section, although very beautiful when grown under glass, is not so well adapted for bedding in the open air as the Golden Tricolor section, on account of the cupping or crumpling of the foliage, induced, it would appear, by the white or silver margins (possibly from their entire freedom from chlorophyl or green colouring matter), being unable to expand in proportion to the green centres: consequently crumpling is inevitable; but, very fortunately, this objection does not in any degree apply to the yellow-margined varieties, possibly from the circumstance of the margins of their leaves not being entirely destitute of this principle. — P. Grieve, *Culford*.

CAMELLIA CULTURE.

In reading the account of Mr. W. Paul's lecture on spring flowers, I was strongly reminded of an anecdote of the late Duke of Wellington. He was urging one of his military friends to enter parliament, and was answered, that having spent the greater part of his life in the army, and given attention chiefly to military matters, he scarcely felt equal to taking an active part in legislation. "Oh," replied the Duke, "you have only to take care not to speak on subjects with which you are not thoroughly acquainted." Now, no one can doubt that Mr. Paul is an authority when he writes on growing Roses and Hyacinths in pots, but if he grows Camellias according to his own directions, I certainly will take an early opportunity of asking to see them.

To begin with grafting, he says this is usually performed in the autumn; is not the spring a much more natural time to graft? Mine are always grafted in the spring and we do not lose one in twenty, so I shall not change to autumn.

Then, he says, the best soil for Camellias is a rough loamy peat; what sort of a soil this is I am at loss to know. Peat we know, and loam we know, but what is loamy peat? "Loam, a dark-coloured rich mould, principally composed of dissimilar particles of earthy matter, as sand, clay, and carbonate of lime, and vegetable matter in a state of decay, with an occasional mixture of oxide of iron and various salts" (see *Worcester*). Is such a soil ever found naturally in combination with peat? It is impossible, because the acids of the peat would be neutralised by the lime, and I have long thought it absurd to make such mixtures. Make a bed of peat mixed with loam abounding in alkalies, and in a very few years you will hardly find a trace of peat remaining. But, perhaps, Mr. Paul intends to recommend a mixture of loam and peat, a very common and I think a very wrong one. In such a mixture peat is evidently intended to act mechanically to keep the loam open, and for reasons above stated the effect can only be temporary; the result is generally a mass of sour soil in which will be found plenty of brown half-dead roots. There are rich fibrous peat soils which will grow Camellias, and such soils are infinitely to be preferred to mixtures containing peat; but though Camellias in peat often have fine dark foliage, they have not the constitution of plants grown in sandy loam, and I contend that fresh turf cut thinly from a rich sandy loam is the only soil fit for Camellias.

Again, Mr. Paul says the time to pot a Camellia is when it has made its growth, or, rather, when its growth is well matured. Is it possible to give worse advice than this? When a Camellia has made its growth it has also made its roots, and if potted at that time the new soil will be almost entirely unoccupied for twelve months. If, on the contrary, it is potted as soon as it is out of flower the roots will almost immediately reach the pot sides.

Then, we are told to turn the plants out of doors when the growth is matured—that is to say, almost immediately after they have been repotted, and, if they drop their buds, to consider ourselves in fault, as they have had too much water at one time, or too little at another. It must be a wonderful chance if they do retain their buds after such treatment, particularly if they have been subjected "to a high temperature to induce a vigorous growth." Is this the way to grow an evergreen almost as hardy as a common Laurel? Grow it in a hothouse in spring, pot it after it has made its roots in an unnatural soil; turn it out of doors to stand all weathers for some months, and then take it back to the house to bloom! We have been taught that two negatives make a positive, and *perhaps* the result of such treatment may be satisfactory. I should like to see it.

When I was a boy the Camellia-house at Wollaton was the finest sight in this neighbourhood, but the Lord Middleton of that day who had taken great pride in it died, and was succeeded by one who had spent his life on board a man-of-war. He told me himself he did not care for a garden, and the only trees worth planting were Oaks and Walnuts for ships and gun-stocks. One of the first orders the gardener received, was not to waste any more coal on the conservatory. When a very severe frost set in, I believe it was in 1837, this order was rescinded, but it was too late, the pipes were frozen up, and though the beautiful climbers which were trained up the pillars of the house were killed, the Camellias were uninjured. Lord Middleton seeing them flower as well or better than ever, never allowed the house to be heated again whilst he lived, and I never saw such plants as they became. Of course if they had been in pots in place of being planted out, their roots might have suffered. These dark Laurel-like bushes, amongst which you might have hidden a bullock, many of them from 10 to 15 feet high, gave me my first lesson on Camellia-growing.

In conclusion, I would ask you if you have often seen such wood as the branch I have enclosed, from plants grown in peat soil or which have been subjected to a high temperature to induce vigorous growth, a process of wire-drawing it may be called, resulting in long but thin shoots the reverse of vigorous. A healthy plant of Camellia ought never to cast its buds, and such an occurrence is rarely seen here, but then our plants never receive more heat than is necessary to keep out frost, and are never turned out of doors.—J. R. Pearson, *Chilwell*.

[The shoots are uncommonly fine and stout, and the leaves intensely green.—Eds.]

APRICOTS AND STRAWBERRIES IN DORSET.

Mr. Radclyffe has sent to us the following extract from a letter he has received from Blandford:—

"I have, I think, the most astonishing early development of out-door Apricots ever seen. What think you of five hundred Apricots set on one tree, and some of them now (April 8th) as large as a good-sized Walnut? The tree is uncovered, and in all other respects comparatively uncared for."

Mr. Radclyffe adds—"Strawberry plants here look first-rate. The best novelty is Dr. Hogg, and it can be confidently recommended. It is a Queen, very hardy in leaf, healthy, a good cropper, and altogether excellent."

TIME REQUIRED FOR GRAPES RIPENING.

In the Journal for March 14th "H. W." wishes to know if there is a given time to ripen Grapes in. My opinion is that there is not. "H. W." does not say whether he wanted them ripe at any given date. Should he require them at a stated time, then the gardener in charge would have to act accordingly; if no special time is named, the gardener would act on his own judgment. I have had no experience in Jersey myself, but am inclined to think that Grapes in Jersey and in the north will require much the same treatment.

To me the idea of forcing Vines to have ripe Grapes in four months is not in accordance with the general practice of forcing the Vine; besides, at certain seasons of the year such forcing must add considerably to the expense of fuel, to say nothing of the extra labour.

I am satisfied that, accommodating as it is, the more slowly the Vine is forced in accordance with its requirements the better. Quick forcing as a natural consequence, as you justly observe, must produce quick exhaustion. To excite the Vine in an unnatural degree must be highly injurious to its well-being.

I know a place where Vines were forced in sixteen weeks.

The case was as follows :—The owner, being ill, was ordered Grapes, which cost 7s. per lb. The gardener thought it a great price, and resolved to risk the experiment of quick forcing on account of his sick master. Accordingly he put his plan in operation, and in sixteen weeks he had ripe Grapes; but I am very much in doubt whether if the same Vines had undergone the operation again they would not have been rendered worthless. I saw them after they had performed their task, the fruit was far from what it ought to be, and the foliage was foxy, aye, very foxy.—VERITAS.

ROYAL BOTANIC SOCIETY'S SPRING SHOW.

THE second spring Show of this Society took place on Saturday last, but, unfortunately, the weather was such as to prevent a large attendance of visitors, being squally and showery in the forenoon, and though the after part of the day was fair the sky continued threatening till night. The principal features on this occasion were Azaleas, Roses, and Cinerarias; and these, with flowering and fine-foliaged plants, made an effective though not large display.

Of Azaleas there were only two collections in the Nurserymen's Class; these came from Mr. Turner, of Slough, and Messrs. Lane and Son, of Berkhampstead, and were awarded equal first prizes. Mr. Turner's six consisted of excellent examples of Madame Miellez and Louis Von Baden, white; Kinghorni and Perfectieu, rose; Beauty of Reigate, white, with occasional stripes of red; and a union plant, being Etoile de Gand and Variegata superba worked together. Messrs. Lane had Reine des Blanches, Iveryana, and Magnificent, white; Chelseni, orange scarlet; Roi Leopeld, salmon scarlet, and of Sir Charles Napier, a finely-bloomed pyramid about 4 feet high.

In the Amateurs' Class, Mr. Wheeler, gardener to Sir F. Goldsmid, Bart., M.P., was first with Alba Cincta, in the way of Etoile de Gand; Duke of Devonshire, scarlet; Marie Louise, crimson; Stella, beautiful orange scarlet, with violet purple blotches in the upper petals; Broughtoni and Semiduplex, neither of which was sufficiently in bloom. Mr. Wilkie, gardener to J. McHenry, Esq., Oak Lodge, Kensington, was second with Optima, salmon scarlet; Marie Louise, Duchesse Adelaide de Nassau, a dense mass of scarlet blooms; Sinensis, and standard plants of Sir Charles Napier and Mrs. Fry, rosy crimson.

For three Azaleas sent out in 1862, 1863, and 1864, Messrs. Lane were first with the beautiful Stella, Elegantissima, white with occasional stripes of rose, a flower of great substance; and Advance, rosy crimson, heavily spotted in the upper petals. Messrs. Ivery & Son had Flag of Truce, white; Madame Dominique Vervaene, delicate salmon pink, irregularly edged with white, and spotted in the upper petals with crimson; and Souvenir de Pronay, rosy crimson. Mr. Turner had Stella, Prince of Orange, orange red, almost destitute of spots; and Charles Enke, salmon rose, each petal boldly edged with white, and spotted in the upper petals with purplish crimson. Messrs. Ivery were awarded a second prize, Mr. Turner a third. Messrs. Ivery also exhibited several seedlings, the best of which were Enchantress and Princess Alexandra, which respectively received first and second-class certificates. The former is white, slightly flushed and streaked with delicate salmon rose, and spotted in the upper petals with crimson, a fine bold flower; whilst Princess Alexandra is white, mottled and streaked with purplish pink, some of the flowers wholly pink, and in others only some of the petals of that colour.

Roses, though prizes were not offered for them, formed the most striking and attractive feature of the exhibition. Those from Mr. William Paul in particular were remarkable alike for the number, brightness, and freshness of the flowers, and the size and health of the foliage. Among them were noticeable Mdlle. Marie Rody, with two magnificent crimson scarlet flowers, a fine specimen of Glory of Waltham, Fisher Holmes, Senateur Vaisse, Prince of Portia; of rose and pink varieties Madame Anna Alexieff, Madame Rousset, Centifolia rosea, Madame Fillion, Madame Bell, Madame Heste, and Madame Damaizin; and of Noisettes and Tea-scented Celine Forestier and Marquise de Foucault. Messrs. Paul & Son had likewise a collection in fine bloom, among which were excellent examples of Madame Fillion, Lord Clyde, Princess Mary of Cambridge, Fisher Holmes, Exposition de Brie, Général Jacqueminot, Charles Lawson, Madame Victor Verdier, Maréchal Niel, Celine Forestier, and Madame Villermoz. Messrs. Paul & Son also contributed five boxes of beautiful cut blooms, of which Maréchal Niel, Maurice Bernardin, Alphonse Belin, Madame Victor Verdier, and Madame Villermoz, were especially fine. Extra prizes were awarded for all three exhibitions.

Cinerarias though not numerous had a very gay appearance, and those shown by Messrs. Dobson, James, and Fairbairn were in excellent bloom. Conspicuous among Messrs. Dobson's plants, to which a first prize was awarded, was that well-known and beautiful rosy-purple variety, Lord Elgin, almost dazzling in its brightness; among the others were Conqueror, crimson self; Miss Smith, white, broadly edged with violet; Eclipse; and Admiration, white, with a broad rosy-purple edge. The first prize in the Amateurs' Class was awarded to Mr. James, gardener to F. Watson, Esq., Isleworth, for well-bloomed plants of Snowflake, Lord Elgin, Perfection, Charles Dickens, Fair Maid, and William Reeves. The second prize went to Mr. Fairbairn, gardener to the Duke of Northumberland, Sion, who pressed his competitor so closely for first that it was difficult to decide which had the better collection; his plant of William Dobson, a bold crimson self, was admirably bloomed; Creamy White, as well as his other plants were also very good. Mr. August, Beddington, was third. For Beatrice, a seedling raised by Mr. Fairbairn, Messrs. Dobson received a first-class certificate. It is a very large, bold, white flower, conspicuously edged with rosy purple.

Among other subjects were Amaryllises from Mr. Burley, of Bayswater, and Mr. Wilcock, gardener to Dr. Pattison, of St. John's Wood; fine-leaved Begonias from Mr. Marcham, gardener to E. Oates, Esq., Hanwell, and Mr. Wheeler, gardener to Sir F. Goldsmid, Bart., and excellent pots of Lily of the Valley from Mr. Bartlett, who also contributed a dozen admirably-bloomed specimens of Spiræa japonica or barbata. These, though only in 48-pots, measured about 20 inches across at the base, and 16 or 17 inches high, and each bore about a dozen graceful white spikes of bloom. It is surprising that so effective a plant is not more generally grown for decorative purposes at this season, seeing that it is of easy culture.

Of British Ferns Messrs. Ivery, of Dorking, sent as usual the best collection, which included Asplenium trichomanes Moulei, a very pretty slender variety; Asplenium fontanum, Cystopteris fragilis angustata, Blechnum spicant heterophyllum, of which the pale green of the young fronds formed a pretty contrast with the dark hue of the older ones; Ceterach officinarum, Scolopendrium vulgare marginato-cristatum, Polypodiums, Athyrium Filix-fœmina formoso-cristatum, a finely-crested variety with lively green fronds as shown, A. F.-f. thysanotum, A. F.-f. pulchellum, also pretty, and a graceful of Trichomanes radicans. Mr. James, of Isleworth, had the second prize for a collection chiefly consisting of Athyriums and Lastreas.

Prizes were also offered for flowering and fine-foliaged plants, and were taken by Mr. Williams, of Holloway, Mr. Wheeler, and Mr. Wilkie in the order of their names, with collections comprising Cordyline indivisa, Variegated Aloe-leaved Yucca, Crotons, Alocasia metallica, Dicksonia antarctica, Eriostemons, Azaleas, Genetyllis fuchsioides, and Dendrobium nobile. Mr. Williams likewise contributed a collection containing Imantophyllum miniatum, Tetratheca ericæfolia, Berenia pinnata, Trichopilia suavis, and other Orchids, together with a fine specimen of the beautifully-striped Yucca quadricolor, Yucca albo-spica, Ananassa sativa variegata, Todea superba, and Hymenophyllum demissum. Messrs. Lane had a plant of the beautiful hybrid Rhododendron Countess of Haddington, with large trusses of its long-tubed rosy blush flowers; also a plant of Edgeworthii, a Sikkim species with large, campannlate, white flowers.

Of new and rare plants a numerous collection came from Mr. Bull, comprising Litebrochia undulata, Maranta rosco-picta; Habenaria margaritacea, with oblong dark green leaves, blotched with white, a promising addition to variegated Orchids; Iresine Herbstii aureo-reticulata, noticed last week; Tradescantia repens vittata, in which some of the leaves are half green half white, while others are broadly striped; Fittonia argyroneura, beautifully veined with white; Athyrium Goringianum pictum, a beautiful and graceful variegated Fern, with reddish midribs shading off to grey, and clended towards the base of the pinnæ; the Japanese Lastrea varia, with green and bronzy fronds; Polystichum angulare parvissimum, and some others. Mr. Williams, of Holloway, sent the rare Vanda gigantea, with a raceme of its large thick blossoms, golden yellow, with conspicuous cinnamon blotches; also a Strelitzia, with an orange and blackish violet flower; Dracæna sanguinea, with long narrow leaves having red midribs; Lindsæa cultrata; a small yellow and brown-flowered Oncidium, and a by-no-means showy Maxillaria, with numerous small purplish spots on a buff ground. Mr. Wilcock, gardener to Dr. Pattison, St. John's Wood, had two Odontoglossums, one being O. Bluntii, and the other a good variety of luteo-purpureum with nine large flowers. From Mr. Shenton, Barnet, came several varieties of Retinosporas, not, however, of a size that their merits could be judged of; and from Messrs. Perkins, of Coventry, Tricolor Pelargenium Queen Victoria, a pretty variety, which was adjudged a first-class certificate; and Mr. William Paul had a similar award for Red Admiral. Mr. Paul also exhibited several other promising variegated Pelargoniums, and the beautiful new double Scarlet Thorn.

TREATMENT OF PEACH AND NECTARINE TREES.

PLANT if possible trees one-year-trained from the nursery, unless you like two-year trees best. After planting, put some rotten manure over the roots, with soil, and water it in. I like to plant in October or November, and I let the trees grow till May before I cut them back. Should there be any shoot absolutely useless I cut it out, but no more; then nail, as soon as of sufficient length, as much wood as will form a good head. I usually let the wood grow all it can in the spring till the following season—that is, I never cut a shoot from the trees till I prune them, say in the middle of May; then I go over the trees and cut out the useless wood, disbud the wood left for another year, take off the embryo fruit where it is too thick, and then nail in properly. By this management I never miss having a crop of fruit. The reasons I assign for this treatment

are, that by having every piece of wood with its leading shoot, the proper nourishment of the tree never ceases to keep properly distributed, you obtain a crop without any covering to your trees, and you avoid all standing in the cold and hitting your fingers instead of the nails in winter pruning. I have had a crop of fruit for the last twenty years under the above mode of managing the trees.

The six Peaches which I recommend are—Chevreuse, Téton de Venus, Noblesse, Bellegarde or Galande, Walburton Admirable, Grosse Mignonne. The following are also good kinds:—Red Magdalen, Royal George, Vanguard (very often sold for Noblesse), Old Newington, Chancellor. The six Nectarines which I prefer are—Elruge, Red Roman, Brugnon, Violette Hâtive, Pitmaston Orange, Hardwicke.—J. Harris, *Nurseryman.*

ROYAL HORTICULTURAL SOCIETY.

Dr. Masters's Lecture, *April 13th.*—The Stem and Branches formed the subject of this day's lecture, the features distinguishing them from the root were pointed out, and numerous illustrations were given of the various forms which these parts assume. The purposes which the stem serves in the economy of the plant were stated as being to act as a channel of communication between the roots and leaves, to expose the latter to the light and air, to serve as a reservoir of nutriment for the plant, and in some cases to act as a substitute for the leaf. For the support of annual plants a small herbaceous stem was usually sufficient, but for those of longer duration, or which are exposed to the wind, a woody stem or trunk became necessary. The way in which the trunk is formed through the greater energy of the terminal bud, and its more favourable position as compared with the side shoots for receiving nourishment and light, was then explained; and Dr. Masters next showed that the different shapes which trees assume depend on the suppression of some buds, the development of others, the position and arrangement of the latter, and the direction which the resulting shoots assume. In the organs of plants there was the same struggle as that which goes on between plant and plant, when a number are growing together, and the same victory of strong over weak. This struggle exercised a powerful effect on the form and habit of the plant, and climbing plants were instanced as a form in which the leaves are as fully exposed to light and air as if they had a thick trunk and branches.

Dr. Masters next pointed out that the underground portions of the stem, such as tubers, corms, and rhizomes, are distinguished from roots by the habitual production of buds, and serve as reservoirs of nutriment, generally containing starch and other substances available for the growth of the plant. Many subterranean forms of stem, it was then mentioned, could change their position by their growth at one end and decay at the other. Aërial stems likewise served as storehouses, some, as in the case of Cactuses, containing large quantities of water, while in others there were resins, gums, and various peculiar secretions.

The power which the cultivator has of altering the form of plants by pruning, grafting, and other operations was then referred to, as well as the effect of these as regards the formation of wood and the production of fruit. The effect of grafting, and especially that of double-grafting, in promoting the speedy formation of fruit-spurs, was also pointed out, and illustrated by specimens kindly sent by Messrs. Rivers.

Second Spring Show, *April 16th.*—This was an extensive as well as most beautiful Show, lacking but one element to render its success complete, and that was fine weather; for though the two conservatory arcades, which the various subjects fully occupied, and the conservatory itself, were warm, dry, and comfortable, the drizzling rain which continued more or less throughout the day very much diminished the numbers and enjoyment of the visitors. Masses of fine Azaleas and Rhododendrons, and a profusion of Roses constituted the leading features of the display, while mixed collections of flowering and fine-foliaged plants, Cinerarias, Lilies of the Valley, Pelargoniums, and other plants served to give it variety.

In the class for nine Azaleas the only exhibition was that of Messrs. Lane & Son, of Berkhampstead, who had a first prize for Gem, Chelsoni, Advance, Elegantissima, Stella, and finely-bloomed plants of Roi Leopold, Sir Charles Napier, Magnificent, and Iveryana. In the Amateurs' class for six, Mr. Wheeler, gardener to Sir F. Goldsmid, Bart., was first with well-bloomed specimens of Marie Louise, Duke of Devonshire, Stella, Broughtoni, Semi-duplex, and Alba Cincta. Mr. Todman, gardener to R. Hudson, Esq., Clapham Common, was second with smaller plants, but in excellent bloom, the varieties being Duchesse Adelaide de Nassau, very brilliant in colour; Princess Royal, rosy crimson; Roi Leopold, Princess Barthilda, Conciuna, purplish lilac; and The Bride, white. Mr. Wilkie, gardener to J. McHenry, Esq., Kensington, who was third, had Crispiflora, in which the edges of the petals are curled or crisped; Burlingtoni, orange scarlet; Coronata, deep rose; a finely-bloomed standard Sir Charles Napier, and a pyramidal plant of Roi Leopold, covered with bloom. The same exhibitor was first for three plants with Sinensis, Duchesse Adelaide de Nassau, and Marie Vervaene, all three in excellent bloom, and the last, though small, being pure white with a few streaks of red, was very pleasing. Mr. Wheeler was second, and Mr. Todman third. The first prize for the best single specimen was awarded to Mr. Fairbairn, gardener to the Duke of Northumberland, Sion, for a plant of Triumphans, forming a regular cone about 5 feet in height, well covered with flowers. Mr. Turner, Slough, was second with Louise Von Baden, bearing a profusion of its fine large white flowers. Messrs. Lane contributed Reine des Blanches, about 3½ feet high, and Mr. Lydiard, Batheaston, a small plant of Extrani, but in very good bloom.

Of Rhododendrons, Messrs. Lane were the only exhibitors in the class for six, but took a well-merited first prize for Augustum, delicate pink; Nero, dark rosy purple; Illuminator, with large trusses of rose-coloured flowers; Vervaeneanum, semi-double, bluish lilac; Griswoodianum, blush; and Erectum, deep rose—all of them moderate-sized plants, and in excellent bloom. Messrs. Lane also contributed a collection of dwarf standards in small pots, and in fine bloom, though not exceeding a foot in height. The first prize for a single specimen went to Mr. Wilkie, for a fine standard Everestianum, with a head measuring 5 feet or more across; and the second to Messrs. Lane, for Toowardianum, bearing numerous large trusses of its rosy lilac flowers.

Mr. Parker, of Tooting, sent a fine half-standard Countess of Haddington, with a head 3½ feet across, and bearing numerous trusses of its charming rosy blush flowers. Most unfortunately it was too late for competition, otherwise it would doubtless have secured an award. This fine hybrid variety, it will be remembered, was first sent out by Mr. Parker. Mr. Batch sent cut blooms of Rhododendrons grown out of doors at Hafodunos, Denbighshire; likewise blooms of Aucklandii, of course from a house.

Roses and their merits will be fully reported on by "D.," of Deal, and in the meanwhile it will suffice to mention the names of the prize-takers, and a few of the varieties exhibited. The first prize for nine was taken by Mr. Turner, in whose collection we remarked fine examples of Senateur Vaisse, Baron Adolphe de Rothschild, Vicomte Vigier, Charles Lawson very fine, Madame Falcot, and Souvenir de la Malmaison, with numerous beautiful blooms. In that of Mr. W. Paul, who was second, we remarked Victor Verdier, John Hopper, and Madame Villermoz; whilst Messrs. Paul & Son, who were third, had Anna Alexieff beautifully fresh, Charles Lawson, Madame Villermoz, and Alba Rosa. Mr. James, gardener to W. F. Watson, Esq., took a first prize, the only one awarded in the Amateurs' class, with plants in good bloom; and in that for the best single specimen Mr. W. Paul had a like award for Madame Alfred de Rougemont, which, although not large, had about two dozen expanded flowers, white tinged with pink, equally distributed over the plant. Mr. Turner was second.

New Roses of 1865 and 1866 were with some exceptions not seen to the best advantage. Charles Wood, deep velvety crimson; Exposition de Brie, violet shaded crimson; Mdlle. Marie Rody, crimson scarlet; Camille Bernardin, Dr. André, Marguerite de St. Amand, Alba Mutabilis, Charles Rouillard, and Maréchal Niel were some of the most noticeable. The last, of course, now requires no commendation. Mr. W. Paul was first; Mr. Turner, second; Messrs. Paul & Son, third. Extra prizes were also awarded to Mr. W. Paul, and to Messrs. Lane, who each showed numerous collections of pot plants, also to Messrs. Paul & Son for boxes of cut blooms.

Among Cinerarias the most attractive were Miss Smith, Lord Elgin, William Dobson, Lady Theodore Grosvener, blue-edged; and Eclipse, white with a broad rosy purple edge. Messrs. Dobson & Son were first, also receiving an extra prize for twelve well-bloomed plants; Mr. Fairbairn, second; Mr. James, third. The last-named exhibitor also had a first prize for six Calceolarias admirably flowered, and of the same excellent strain as that which he usually exhibits.

Prizes were also offered for Amaryllids. Messrs. Veitch and Mr. Burley, Bayswater, were the only exhibitors, the former being awarded the first prize for their collection, in which Ackermanni pulcherrima, with large, deep scarlet flowers veined with blackish red, and Baumanni grandiflora were conspicuous.

Auriculas, Polyanthuses, and Pansies, will receive special notice at other hands. For Auriculas, Mr. Turner, of Slough, took a first prize in the Nurserymen's class, with beautiful examples of Miss Giddings (Read), Richard Headley (Lightbody), and Mary Ann (Fletcher), Grey-edged; Unique (Dickson), Prince of Wales (Ashton), and Lady Richardson (Gairn), Green-edged; Crucifix (Clegg), Fair Maid (Lightbody), and Pillar of Beauty (Hughes), White-edged; Eliza (Sim), Meteor Flag (Lightbody), and Stadtholder (Gorton), Selfs. Mr. James, who was first in the Amateurs' class, had a good eight, likewise taking a third prize for Alpines. For Polyanthuses, Mr. Wiggins was first, Mr. Turner, second; and for Pansies in pots, Mr. James was first. Good stands of cut blooms from Mr. James and Mr. Hooper, of Bath, also received first and second prizes.

Lily of the Valley, in excellent bloom, from Mr. Reeves, Campden Grove Nursery, Kensington, had a first prize; and Mr. Salter, Hammersmith, was second with beautiful potsful of the variegated sort in fine bloom.

Miscellaneous collections of plants in flower consisted for the most part of subjects which had been exhibited on the previous Saturday at the Regent's Park. Among them were Acacias, Ixoras, Genetyllis, Vincas, Eriostemons, Azaleas, Rhyncospermum jasminoides, Odontoglossums, Vandas, and other Orchids. Mr. Wilkie was first, Mr. Williams second, and Mr. Wheeler third.

Other subjects, for which classes were not provided, consisted of a large and beautiful collection of Chinese and Ghent Azaleas, Rhododendrons, including Countess of Haddington and Dalhousianum, Roses, Deutzias, &c., contributed by Messrs. Lane; a very pretty mixed collection of Tulips, Lily of the Valley, and Spiræa japonica from Mr. Bartlett, of Hammersmith; British Ferns from Mr. James; basketsful of Mrs. Dix and Miss Watson Tricolor Pelargoniums from Mr. Watson, of St. Albans; and many fine varieties of the same class of Pelargoniums from Messrs. E. G. Henderson, who also had the beautiful Silver-leaved Meadow Grass and the pretty Aucuba-leaved Daisy. Mr. Tanton, Epsom Nursery, exhibited a remarkably fine plant of Cyperus alternifolius variegatus; Mr. Wiggins, Isleworth, a fine collection of Cyclamens in 60-sized pots; and from Mr. Earley, Digswell, came a box of cut flowers containing Gardenias, Roses, Cinerarias, Persian Lilacs, Acacias, Begonias, Clianthus, &c., together with flowers of "Trichosanthes cucumerina," like lacework, but of which the correct name is doubtful. For the above exhibitions several extra prizes were awarded, which will be found in the published prize list.

Floral Committee.—A very nice collection of plants was furnished for the inspection of the Committee, and several novelties of various merit were to be found among them. In the exhibitions of the Society, the new plants and florists' seedlings seem always to excite considerable interest. Mr. James Butcher exhibited a seedling Auricula; Messrs. Perkins & Son, Coventry, a seedling Tricolor Zonal Pelargonium, Queen Victoria, which it was requested should be sent again to compare with others. It is decidedly a good variety, and will probably take a good position among its numerous relatives. Messrs. Veitch sent a large and valuable collection of plants, among them Sphærogyne peruviana, a handsome, large-foliaged plant; Coleus Veitchii, from the South Sea Islands, very showy and distinct, the centre of the leaf very dark, with a bright green margin. A first-class certificate was awarded it. Also Dieffenbachia Pearcei, which received a second-class certificate; Panicum variegatum, from the South Sea Islands, with white and red variegation, very distinct, first-class certificate; Hippocyrta brevicalyx, a very curious flowering plant, resembling in foliage Gesnera, and having globular orange flowers, second-class certificate; Franciscea calycina major, with beautiful large lavender flowers; a new species of Nepenthes, which it was requested should be sent again; Primula cortusoides amœna, a beautiful spring-flowering Primrose, quite hardy; Gymnostachyum Pearcei; and the graceful Hotein (Spiræa) japonica, a forced hardy herbaceous plant most useful at this season for decorative purposes. Mr. Bull sent several new Ferns—namely, Lastrea Filix-mas Barnesii, which received a first-class certificate; Athyrium Goringianum pictum, a distinct variegated form, and very beautiful, which also had a first-class certificate; Athyrium Filix-fœmina pulchrum, which had a second-class certificate; Athyrium Filix-fœmina elegans; also Habenaria margaritacea, and Camellia Lavinia Maggi rosea, which was awarded a second-class certificate. This is a sport from Lavinia Maggi, but very inferior in form and beauty.

From Messrs. Dobson, Isleworth, came seedling Cineraria Beatrice, deep white centre, with a magenta margin; second-class certificate. Mr. W. Paul sent seedling Zonal Pelargoniums Rouge et Noir, Prince Silverwing, Red Admiral, Topaz, and Jason, a bright yellow-foliaged variety, which was awarded a first-class certificate. It is fully early to decide upon the merits of these sporting varieties; when planted out of doors their merits will be more fully developed. From the same came also Aucuba japonica ovata, a green-foliaged variety, which had a first-class certificate; Aucuba japonica salicifolia to be seen again; Alnus aurea, a yellow-leaved plant, which received a first-class certificate as being useful for a shrubbery or plantation; and Cratægus oxyacantha coccinea flore pleno, which had a first-class certificate. This is certainly a plant which cannot be over-rated; the intense bright red colour, and the numerous clusters of the double flowers make this Cratægus invaluable; no admirer of this charming family can be without it, all other pink varieties are truly in the shade beside it, beautiful as they all are. Mr. S. Parsons, Turnham Green, had a seedling Azalea Beauty of Fairlawn and Azalea Rival, not equal to well-known named sorts. Mr. S. W. Pilcher, Plaistow, sent seedling Alpine Auricula Emma, deep rosy crimson, with a yellow centre; it was awarded a second-class certificate; also Veronica chamædrys variegata. Mr. Parkes, gardener to G. Cooper, Esq., Old Kent Road, sent a collection of cut Orchids, among them Odontoglossum tulipiferum (?) and Dendrobium thyrsiflorum, also plants in fine bloom of Odontoglossum Alexandræ. A special certificate was awarded for these handsome spikes of flowers. Where were the far-famed, as far advertisements make them so, new Violets? Not even the Czar put in an appearance. Surely if worth anything the new double kinds ought to have been introduced on this occasion to the public. The Pansies were all that could be wished, and some of the finest kinds ever exhibited, but the Violet ought decidedly to have been represented at this meeting, we mean that highly-scented modest flower with nodding head.

Fruit Committee.—Mr. Lydiard, Batheaston, sent a good dish of Alice Maude Strawberry, Lydiard's Improved, Rifleman, and Hedsor Winter Prolific Cucumbers, and a dish of a white seedling Potato, very good for this season. From Mr. Melville, gardener to the Earl of Roseberry, Dalmeny Park, came Melville's Imperial Early Cauliflower Broccoli.

General Meeting.—W. Wilson Saunders, Esq., F.R.S., in the chair. The business was entirely of a formal character. Seven new Fellows were elected, and the St. Mary's Church Cottage Garden Society, and the Spalding Floral and Fruit Society were admitted into union.

SUDDEN DEATH OF PANSIES AND CINERARIAS.

In a former number of your Journal the question "Why Pansies died off suddenly, or some parts of them did so?" was asked. In a recent number the same question is put, touching the sudden death of Cinerarias.

I think I can answer both your correspondents, having, like them, been a sufferer, and in both instances, but, after close inquiry, a discoverer, too, which they do not seem to have been. First of all, let me state a physiological fact—a ring of bark taken off down to the wood of any woody vegetation, tree or plant, if complete, destroys the vitality of the roots and ultimately that of the plant. Further, though scientific men know the fact, society in general does not, nor do all gardeners, that the roots lift, by a special system, the nourishment from the soil for the plant, but do not partake of it themselves while it is in a crude state; the roots, to be healthy, requiring the intervention of bark, the same as the trunk of a tree or plant does. The bark descends in continuation from the stem, however altered in appearance, and by it the sap which the roots lifted up into the tree descends in its improved character. The roots are merely organs of nourishment, and as organs must be kept healthy, or they will not perform their duties to the tree or plant. Roots, as I have before remarked, do not nourish themselves directly, but by means of the sap descending by the stem. If by any chance a complete interruption to the flow of sap is made at the level of the ground, just where the sap-bark begins, by cutting off the bark down to the woody fibre, the roots will infallibly die, the plant following.

With reference to Pansies, Cinerarias, and some other similar plants, dying off, I found a ring of the bark completely eaten away to the woody fibre in each instance. It would appear as if the plant supported itself for a few hours after this result had taken place, by the sap in store, and that the roots in the meanwhile became useless, the plant by the morning dying suddenly, however well it looked overnight. The night being the time when plants draw on their roots most largely, and the leaves giving out most freely their gaseous vapours in the morning—that is the time of our finding a withered plant. (?)

In some cases I thought woodlice barked the plants, and so they do, but they bite here and there, up and down the stem, for half an inch, and do not completely eat away the bark, unless they are very numerous, crowding and poisoning the Pansy root as well as eating it. Wireworms, however, are the worst of all pests in the flower garden. They keep just at the line of junction between the hard bark of the stem of the plant, and the softer bark of the root, and just below the earth one wireworm will thus concealed work away at the bark, entirely encircling the plant, and as surely destroying the roots by cutting off the supply of nourishment these derived from the plant's stem. There is no sure remedy but catching the wireworms, nothing else will be effectual.—M. D.

CHRYSANTHEMUM CULTURE.

The Chrysanthemum is one of our most useful autumnal flowers for greenhouse and conservatory decoration. It comes into beauty when other flowers are scarce, and enlivens our plant-houses at the dullest season of the year. With careful cultivation it may be grown to any size, be trained to any shape, or adapted to almost any purpose.

The plants may be easily increased either by cuttings, suckers, layers, or dividing the roots. I consider the most easy and business-like way, or at least that by which the best foundation is laid for future success, is by cuttings, and as this is the mode I generally adopt I shall treat on it only.

The cuttings are taken from the old plants early in March, or about the middle of that month. This season I took off my first batch of cuttings about the 15th of March. They should be about 3 or 4 inches long, and, the lower leaves being trimmed off, should be cut just below a joint. Three or four cuttings are inserted in a 60-sized or three-inch pot, in a compost con-

sisting of rich turfy loam and leaf mould in equal parts, with a liberal admixture of sharp sand, carefully attaching the name to each variety. The pots are then placed in the propagating-house, plunged to the rim in cocoa-nut fibre; and as the house is glazed with rough plate glass, but little shading is required. The cuttings receive a gentle watering from a fine-rosed watering-pot, so as to check too rapid evaporation when they are deprived of the support of the parent roots, as well as to settle the soil about them. The atmosphere is kept moist, and they receive a gentle bedewing from the syringe on most days. They will strike readily in a Cucumber-frame or in a vinery at work, or, where no better accommodation can be afforded, the cutting-pots may be plunged under hand-lights in the open air. I find that in about a month or five weeks the cuttings begin to grow and the pots to fill with roots.

The plants, for such we must now call them, being rooted, are removed to a situation where they will receive more sun and air; the point of each shoot is nipped out, and they are shifted into six-inch pots. It is important to shift immediately the roots reach the sides of the pots, for if they become cramped in the small pots the well-doing of the plants will be considerably affected. The soil used for this potting is somewhat stronger than that employed for the cuttings. The Chrysanthemum is a luxuriant grower, and delights in a rich compost; with liberal treatment it will reward the cultivator with glossy green foliage, and a profusion of beautiful flowers. I now use a strong turfy loam, with about one-fourth of decomposed vegetable mould, a little charcoal, and a good quantity of decayed cow and sheep dung, the latter put on a hot iron or in an old tin vessel, and placed over a fire for some time to destroy insect life. In this compost the plants will grow freely, and in due time produce a fine display of bloom. They must gradually be hardened off, and, when there is no danger apprehended from frosty nights, should be plunged in a bed of coal ashes out of doors. When handsome specimens are desired, with luxuriant green foliage to the rims of the pots, the plants should be placed at a sufficient distance apart not to interfere with each other, for if the leaves are allowed to intermingle too freely the lower ones turn yellow and become unsightly. Instead of a position facing due south, one with either a south-east or south-west aspect suits them better. When the roots have again reached the sides of the pots I give another shift, at the same time stopping all the shoots to keep them dwarf and compact. About the end of July I give their final shift, using on this occasion 10 or 12-inch pots, according to the size of the plant and the variety about to be potted. At this potting they should be finally stopped, and all the shoots carefully tied out to neat stakes.

During the growing season the plants require copious supplies of water, and they should never be allowed to flag from the time they are removed from the cutting-pots until after blooming. In dry weather they will be greatly refreshed and benefited by a watering overhead once or twice a-day. If it is desired to secure fine heads of bloom and very large flowers, the plants should be supplied with manure water at least twice a-week.

About the beginning of October the plants should be removed into a cool house, where they will be protected from dashing rains and severe frost. The front of a Peach-house is well adapted for this purpose. It is not safe to allow them to remain out of doors late in October, as we are then never secure from frosty nights. Last season many Chrysanthemums were completely destroyed owing to being allowed to remain too long out of doors unprotected. They may be removed into the conservatory or greenhouse as they come into flower.

I have sometimes noticed when the plants have been removed in-doors, that though well set with buds and promising to go on prosperously, yet soon afterwards they have drooped, and many of the buds have died off without coming to perfection. This, I presume, is caused, as a rule, by the roots being allowed to run freely through the holes of the pots into the soil; and from numerous rootlets being broken off on the removal of the pots, the plants are deprived of a vast amount of nourishment, and consequently sustain a check, discoverable by the leaves flagging and the buds withering. This evil may be avoided by moving the pots before the roots run into the soil, and repotting the plants when the pots are filled with roots.

When the blooming season is over the flower-stems may be cut down, and the plants plunged in coal ashes in a cold frame, or in turf pits covered with spare sashes, where they will have slight protection from frost. As Chrysanthemums are nearly hardy but little care in winter is requisite, except occasionally to supply a little water. The old plants may be planted out in the mixed borders, in open places in the shrubberies, or at the foot of walls bounding the flower garden. In the southern counties in favourable seasons I have frequently seen them produce a gorgeous display of bloom.

It is unnecessary for me to advert to the many varieties in cultivation. I would refer all intending purchasers, as well as all interested in the cultivation of this useful flower, to the valuable article by "D.," of Deal, on "Chrysanthemums New and Old," at page 100 of the present volume.—Quintin Read.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Stir the soil frequently among young crops, and destroy weeds as they appear. *Asparagus*, as soon as the young shoots are from 3 to 6 inches high, let the plantations be made. *Broccoli*, let a sowing of all winter and spring sorts be made forthwith. Cape Broccoli and Cauliflower for Michaelmas may, however, be sown a week or two later. *Carrots*, continue to sow successions of the Horn—indeed, sow a bed every month, from January to September. This is the best way to be independent of the grub. *Cucumbers*, the sort for ridges should be forwarded immediately, also *Tomatoes* and *Vegetable Marrows*. *Potatoes*, this is an excellent time to plant a full crop; Kidneys with well-protruded sprouts, or other early kinds, planted now will be a little later than those planted in February. Planting them, however, involves a little care; the sets should be placed in baskets, a single layer thick, on damp litter, and handled as carefully as eggs; they should by no means be planted during either sunshine or wind. See that plenty of *Kale*, *Savoys*, *Brussels Sprouts*, *Leeks*, *Scorzonera*, *Salsafy*, *Beet*, &c., is put in without delay.

FRUIT GARDEN.

Recently-planted fruit trees should be inspected in case they have been loosened by the winds; for although deep planting is not supposed to have been practised, yet the soil should be kept in close contact with the stem, quite as high as the surface level. It is necessary that all fruit-tree borders should be well drained, to prevent the stagnation of water at all times, but with this provision there will be no danger from all the rain entering the borders which falls upon them between this and August, even if it should be abundant. The climate in front of a south wall is an artificial one, chiefly as regards an increased temperature, and with this there is afforded no corresponding increase of moisture. The latter must be supplied by watering, but the less this becomes necessary the better. If the border is smooth, firm, and sloping, heavy rains are carried off by the surface, and lost as regards the roots of the trees: therefore from this time until August, or the period of ripening, keep the surface loose so that rain may enter freely. Weed Strawberry plantations.

FLOWER GARDEN.

Potting and sweeping lawns should now be regularly attended to in suitable weather. Finish off new work, if not already done, without delay. Roll walks to make them firm before dry weather sets in; edge and sweep them after rolling to give them a neat appearance. Any tender Roses that have suffered from the late severe winter, and which are now breaking, should be pruned, but leave such as have not begun to grow until the season has advanced a little. Shrubs should also be looked over in the same manner. Continue sowing annuals wherever required. A thorough re-arrangement of all the herbaceous tribes should take place every spring; if this has not been attended to no time should be lost in carrying it out. Some of the grosser kinds form too large masses in time, and thereby destroy all proportion in the borders and beds.

GREENHOUSE AND CONSERVATORY.

With the advancing season plants of vigorous growth will now be making rapid progress; great attention must therefore be paid to regulating and training the branches. Climbers, in particular, will require to be kept in almost daily subordination. It is a question whether trellises of various fantastic devices are the most appropriate, either for display or convenience. The most simple forms will be found to answer all practical purposes better, and may be in quite as good taste as many of the grotesque trellises in use. This, like all other matters where correct principles of taste are not often brought to bear, is usually overdone. Variety and intricacy, and what is termed originality, are too frequently mistaken for ornament. Nothing can be ornamental, strictly speaking, unless the principles of

design form an essential element in its execution. Plants of shrubby growth will require to be stopped back, so as to give stability to the plants as well as form. This will enable the cultivator to dispense with stakes in a great measure, for after all, stakes are unsightly appendages to exotic plants. Great care should ever be bestowed on watering pot plants. Too much, too little, or an injudicious mode of application are equally fatal to high cultivation. Very many plants are seriously injured at the periods of shifting or "potting off" by improper watering. It has been the fashion to recommend what is termed a thorough soaking to newly-potted stock, and it is to be feared that in this very act the foundation of what is termed sourness is frequently laid. A very fine-rosed watering-pot and slight applications of water, at intervals, soon after potting, are the best means as a general rule to penetrate the mass and to cause the particles of soil so to arrange themselves that the atmospheric influences shall be somewhat modified, but by no means intercepted. There is, however, no good reason why all plants should be watered immediately on shifting them. When a plant has no ball of earth the water should, of course, be made to penetrate the whole mass in order to prevent desiccation, which would sometimes ensue through extreme porosity in the new soil. When, however, the subject is a plant—say a Camellia, with a hard-wedged ball, a steeping overhead in water for an hour is a preferable course. After this, frequent syringings or waterings with a fine rose will be the soundest policy for a week or two afterwards. See that no plant suffers from drought in the conservatory. Those planted out will now require thorough waterings. The larger specimens in tubs or pots must also have a most liberal supply, provided the drainage is complete. This is the period for the free use of liquid manure, but take care that it is perfectly clear. Large Orange trees should now receive a copious supply; where these trees produce gross wood, disbud such or remove it altogether, and let the lower wood take its place; this will induce fruitfulness. See to the cuttings of Heaths as soon as the wood is in order. Fumigate the moment an insect appears. Some of the hardwooded plants of no particular importance might be removed at this period in order to furnish more room for growing young stock and fine specimens in flower. A slight protection will, however, be necessary. Old lights, or a tarpauling on poles as a lean-to, the lowest part next a south wall and the front opening well to the sun, would do exceedingly well for them. Mats may be hung at the sides at night.

STOVE.

Pay due attention to watering, shifting, and stopping stove plants in general. Make cuttings as they can be obtained in a young state, of Geissomeria, Plumbago, Eranthemum, Justicia, Clerodendron, Vinca, Euphorbia, Brugmansia, Begonia, Thunbergia, &c., in order to keep up a succession of clean young stock. See that the growing Orchids have abundance of atmospheric moisture, with a liberal circulation of air early in the morning, shutting up closely betimes, and taking care to observe moderation in the use of fire heat, in order that a pure atmosphere may be inclosed for the night. Growing Dendrobiums will now require liberal supplies of water, and Air-plants on blocks frequent syringings.

PITS AND FRAMES.

Look to tender annuals and cuttings during dull weather, and see that no damp collects amongst them. If this should make its appearance more air and much less water must be given. This is a good time to take off the tops of early-struck cuttings, and to put them into cutting-pots for store; if not wanted for beds, they might be planted out in borders after the beds have been filled. Keep up a gentle heat for tender annuals, and attend to potting-off and shifting as the plants require it. Continue to harden off such plants as have made sufficient growth to prepare them for beds. This is an important point in bedding-out, as sudden exposure nearly, if not quite, destroys them.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Trimming Box-edgings.—A few gaps having shown themselves, and some of the higher, straggling twigs being browned by the frost, we had the Box cut and put in good order for the summer. Could we have reckoned on being able to do this a month hence, we would have preferred it, as then the fresh growth would come so quickly that the edgings would present no brown scraggy appearance. If we have mild weather with frequent showers, the edgings will remain green as the shears have left them, but if we have dry frosty winds, we may expect that for a few weeks the edgings will have a brownish look. Hence, when trimmed only once a-year, we prefer doing the work in September as then they continue green all the winter, spring, and summer. When the edgings are above 3 inches in height they look cumbrous and are a harbour for slugs, snails, &c. We have often done this work with a sharp scythe, but it requires a first-rate scythe-man and a very firm wrist, and even then it is difficult to prevent the point of the scythe dipping in too much at times so as to interfere with a straight line. A good man used to the shears will do nearly as much, and the work will be better done. In straight lines a stout line is stretched along the middle of the Box, the two sides clipped, and then the top cut over, the workman needing no guide but his good eye.

Almost finished Potato-planting, the ground being in good order. Sowed Turnips, Radishes, and Lettuces, on a raised border. We generally sow *Turnips* thinly in rows 2 feet apart, and *Radishes* in rows between them, the latter being all pulled before the room is needed for the Turnips. The White Turnip-rooted Radishes are very useful for soups before Turnips come in. Our stored Turnips are keeping badly this season, going at the heart. Those growing out of doors from late autumn sowings are just Turnips to look at, as when the top grows they become hard. A good juicy Turnip from this time cannot be had except by early sowing under glass, and that makes them expensive, until they come in from open-air sowings.

For general purposes we have long used only three kinds of Radish—the Short-topped Long Scarlet, and the Red and White Turnip-rooted. Other sorts, as the Black, Purple, &c., are hardier for winter, but then they are hard too when used. The White Naples looks well on a salad plate, but it, too, is generally more stringy than the common Short-topped. Of Turnips we like the Snowball and the White Dutch for early use, and a green-topped strap-leaved kind is also very early, quite as early as the Early Stone; but for the general crops we prefer the American Red-top, which is crisp, rich in flavour, and pure white-fleshed, the latter consideration being as yet too much a matter of importance at most tables. For flavour we prefer some of the yellow kinds, as the Maltese; and for a wholesome dish to satisfy the appetite with good food, commend us in winter to a well-boiled well-mashed Swede.

Ran the Dutch hoe among Cabbages and other growing crops, and, if a few dry days continue, will do the same with all parts and crops to which we can have access.

Peas.—Sowed more Peas and Beans. It is right we should mention here that our first sowing out of doors has not come in so soon as we expected, and on examining into the cause we find they are too deeply covered, and that a few seeds will likely go in consequence. A depth of 2 or 3 inches is quite enough at this season, 2 inches, in fact, being ample; but we find ours are covered from 3 to 4 inches, from the earth being piled over them. After this we prefer sowing in a rather wide drill, and deep enough, so that when the Peas are covered the opening shall be from 1 to 2 inches below the surrounding level, for then it is much easier watering the Peas if they require it in summer.

Cleared off the quarter of old Cabbage stumps that stood the winter, laid it out for beds for *Celery*, 3½ feet wide, with four-feet spaces between. Dug over the four-feet spaces, on which some material from the rubbish-heap had previously been placed. Took a good spit from the trench intended for the Celery, and placed the soil on the space between; and then on every alternate raised bed we will sow a row of Peas, and then on the other dwarfer Beans, &c., so that we shall have no difficulty in watering the Celery. Growing chiefly dwarf Celery, we have given up deep trenches. When the dung is added and the trench well dug over, the Celery-bed will not be much below the surrounding ridges, and the not sinking it deeper is a safeguard against rotting and damping in winter. When we were obliged to use these Celery-trenches for bedding plants in the first place, we could do no good with Peas between the beds; but as we think we can dispense with the beds for the above purpose, we will revert to an old favourite plan of ours—namely, cutting out the Celery-beds early, sowing with Peas early on the raised beds, and then cropping the space intended for Celery with early Potatoes, Lettuces, &c. We never had better Celery, and procured with less trouble, than when the trenches alternated with raised beds, on which were Peas as the main crop, and Radishes and Spinach at the sides. The Celery in the early part of the season is much benefited by a flickering shade, such as it would obtain naturally in the bottom

of a ditch, with a few twigs waving above it to break the force of the sunbeams.

Asparagus.—Threw a sprinkling of salt over the plantation, and turned the ridges of a piece of ground, previously well trenched and manured, intended for planting. We find no simpler plan where much is to be taken up and forced, than planting in rows from 2 to 2½ feet apart, and if the ground is stiff, making the rows raised as flat ridges. The annual dressings will fill up the hollows. A good old plan for regular beds, is to take out a deep trench, and of proper width, in winter; collect in that trench all the weeds, prunings, and refuse vegetables about the place—and drainage will thus be secured—follow with a bed of fermenting material in spring, cover with soil, and use the bed for Cucumbers and Vegetable Marrows in summer, and then a little working will secure a first-rate bed for planting Asparagus in the following spring. Where practicable, from having the young plants on the place, it is of advantage to have them grown 2 or 3 inches above ground before planting, and during that operation never to allow the roots to be dry.

Cucumbers in a pit and in frames we have been obliged to smoke with tobacco paper, as green fly made its appearance, owing, we believe, to the plants being more covered than usual in the dull cold weather. The hot water has beaten the frame this year by a few days. The first spring fruit from the pit was from a plant that was not wanted, and which stood for a good while in a 6-inch pot; as it showed a nice fruit the bottom of the pot was broken, and pot and all placed inside a 12-inch pot. We have not used pots so much as we formerly did, chiefly from not having pots large enough handy; but many years' practice with pots and boxes, with and without bottom heat, enables us to corroborate all that is said of the good results of that system in a recent number, as practised by Mr. Cramb, of Tortworth. When the pots were large we used to plant 6 or more inches from the rim, and earth up by degrees, using only slight surfacings at a time, and not adding this surfacing until the previous surface was covered with healthy roots. If the pots were too shallow for this we used to put rings of zinc or firm turf round them, and thus earth up the plants gradually. Wherever any of the dread diseases that afflict Cucumbers appear—and as to the curing of which, besides fresh soil and frequent planting, we can say nothing satisfactory—we would heartily recommend the growing in pots as one of the most likely means of surmounting the difficulty. Treated as above, we have had 16 and 18-inch pots standing on the top of a rickety flue in a Pine-stove, separated from the flue by a couple of bricks, and a pan of water between the bricks, or set on the flue close at hand, and the plants in these pots would frequently produce freely for a couple of seasons. The late Mr. Ayres, father of Mr. W. P. Ayres, was a most successful cultivator of Cucumbers in pots, and as far as we recollect, he pointed out to us more than thirty years ago plants that were upwards of two years old. The mere age is a matter of less importance—it is mentioned chiefly as a curiosity; but the necessary curbing of the roots, and the lessening the space of the feeding ground, seem to promote enduring health as well as increased fertility. As several times stated, so convinced are we that Cucumbers do all the better with a limited amount of feeding ground, that the soil in our pit is only about 2½ feet wide, and in our six-feet frames the earth only occupies a width of about 2 feet, strong slabs generally separating this earth from the back and front of the bed, though all is earthed over for the sake of appearance; but the sides, back, and front have only from half an inch to an inch of soil, whilst the centre where the plants stand has a depth of from 15 to 18 inches.

We may here, also, mention, as bearing on the same principle, that we know of no plan equal to growing in good-sized pots in order to obtain good and heavy Melons in proportion to their size. We question if we could please ourselves in giving any reasons why in such a mode of culture great weight in proportion to size should be such a frequent result, but scores of times we have been struck with the fact. This, we may add, was chiefly the case when the Melon was suspended; but the additional solidity and weight were not solely owing to this suspension of the fruit, as, in the same house, with fruit equally suspended, those grown in a bed were as a general rule less distinguished for weight than those grown in pots, the pots being merely set on the bed and the plants not rooting at all or but little into the soil. Were the juices better elaborated owing to the roots being unable to give the foliage so much to do?

FRUIT GARDEN.

We have been unable as yet to finish nailing some of our protected trees; but that is of less importance, as most of the pruning had been done. Untied the Currant and Gooseberry bushes that had been tied up in the faggot style, and then limed. There will be plenty of fruit this season if all goes on well. The sound of the gun has, no doubt, helped. No report of a gun was heard last year. There was no tying up of the bushes, and by the middle of March, the budless bushes were enough to make one melancholy. We would say, then, that where birds are troublesome, the tying up of the bushes after they are leafless in autumn, and dredging them over with lime, is worth a trial by way of preventive. Of our dwarf Pear trees, the two that have suffered most from birds this season, were the two fullest of buds and earliest, and in the severe frosts of March we placed some tall evergreen branches round them; but we had to remove the branches, or a single fruit-bud would not have been left, the branches being more enticing to the birds than even a net, and that if not thoroughly secure does as much harm as good, as the winged tribes will not be satisfied until they know all about what is beneath it.

Orchard-houses.—We are keeping the latest as open as it will be safe, and the bloom is still beautiful; the earliest house we shut up early, and if cold put a little fire in our stove, which we alluded to lately, and which since our little alteration has given no trouble. If there is a fire you feel the genial atmosphere as soon as you open the door, without the slightest sensation of dry heat. A few minutes after lighting, the stove has an effect upon the atmosphere of the house. For all large houses we would employ hot water; but where economy in heat is to be a consideration, nothing will equal a stove inside of a house, if properly set and properly managed. In this house we have gone over the trees twice, nipping and removing foreright shoots, but not taking away many shoots at a time.

Strawberries.—The weather has been rather favourable, the fruit which ripens is of tolerable flavour, and the setting now is all that could be wished. We mentioned a few weeks ago that for years we had seen little of the fly on forced Strawberries, but though not an insect of any kind has as yet appeared on the Peach trees, we have had to smoke the house twice or thrice, on account of green fly on the Strawberries. As the smoking, do it as you will, is rather an expensive process, we tried at first what the finger and thumb would do, but the insects came here and there so thickly on the central young leaves, that smoking had to be resorted to. Now, as before housing these plants a good portion of the old leaves were twisted off, the surface soil removed—say, for the sixteenth of an inch, and fresh-aired compost added, there seemed no way for the green fly to come, unless from eggs that had been inserted in the central buds some time last autumn.

ORNAMENTAL DEPARTMENT.

Finished turfing, and glad it was done, as it is late enough if all trouble afterwards is to be avoided, though we have turfed successfully in the dog-days; besides, at this season there is much routine work demanding attention. All evergreens may be pruned still, but the sooner the better before they push afresh. We must take the first opportunity of preparing beds, regulating herbaceous plants, &c.

We referred to Neapolitan Violets some time ago, old plants that rather disappointed us before the new year, and hence we recommended planting afresh every year; but these old plants —that is, those which have been two winters in the same bed, have done remarkably well all the spring-time since the middle of January, and produced larger flowers than are generally to be had from younger plantations.

Planted out under protection some Calceolarias, and will go on as opportunity offers. Potted and placed singly in pieces of turf lots of bedding plants, moved Pelargoniums to cool vinery preparatory to moving to conservatory. Potted young plants for autumn blooming, fresh regulated conservatory, and will bring the most forward blooming Camellias and Epacrises into the vinery to cause them to make their wood. Epacrises and spring Heaths stand pruning back freely, but only so far as last year's wood is concerned, and not that which is older. Pricked out numerous seedlings, and made a good many cuttings, as they will yet be time enough for planting out. In wet days, as Saturday, had plenty to do in cleaning and mending glass, potting, and other work.—R. F.

COVENT GARDEN MARKET.—April 17.

A general depression pervades our market in the demand for all but the most common articles, and prices recede accordingly; Pines, Grapes,

and Strawberries being in excess of what is required. A few Cherries from the south of France have arrived this week in tolerably good condition, and other imports are becoming heavy.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

FAILURE OF SUPPLY (*G. C. K.*).—Messrs. Marshall & Co. and all other booksellers, as well as the proprietors of railway bookstalls, receive their supply on the morning of our publication. The failure is not with us.

RUBUS LEUCODERMIS (*G. S.*).—We do not remember this plant being mentioned in our columns. It is one of the plants introduced from North-western America by the ill-fated Douglas in the year 1826. Whether it requires a wall to ripen its fruit we cannot say.

BOOKS (*H. C.*).—"The Science and Practice of Gardening" can be had, post free, from our office if you enclose forty postage stamps with your address. (*R. S.*).—We know of no separate work on Melon culture. (*Axios*).—We do not know any book on Tea culture in India. Mr. Fortune's volumes on China contain some information on Tea cultivation. There is much information on the subject in the fifth volume of the "Transactions" of the Agri-Horticultural Society of India, which we have before us.

EPIMEDIUMS (*A. H. of B.*).—Without seeing flowering specimens no one can tell the names of the plants you have. Epimedium grandiflorum has white flowers, and is a native of Japan. E. pinnatum has yellow flowers, and is a native of Persia; there is a drawing of this in the "Botanical Magazine," *t.* 4456. The seed of the bee flower, Cleome integrifolia, cannot be obtained here at present. It might be obtained by post from some seedsman in Chicago, probably.

MULBERRY TREES BEARING EARLY.—"In reply to your correspondent B. P. Bartlett (page 266), I would say that last autumn I bought of Mr. Rivers a potted Mulberry about 3½ feet high, which is now, in a warm orchard-house, a mass of bloom. It is not for me to publish any further particulars of these extraordinary trees, but I recommend friend Bartlett to buy one. I had a common plant for years in a pot under glass, till I turned it out in disgust. I have heard of the plan you recommend having succeeded, and indeed saw such a plant once at Weybridge, but it was much older and larger than Mr. Rivers's plants.—G. S."

POLYANTHUSES (*Richard Dean*).—There are four very promising flowers among the selection of Polyanthus. They appear to have a circular form, and the lacing round the petals is smooth and distinct. It would be much safer to judge of their merits from seeing the plants growing, and thus learn their habit and style of truss. Could you not send them to the Floral Committee of the Royal Horticultural Society?

PROPAGATING RHODODENDRONS (*Sunny*).—Rhododendrons cannot be successfully propagated from cuttings. They are increased from seed, layers, and graftings.

TRICOLOR PELARGONIUMS (*H. H. B.*).—The leaves you sent marked "Princess Lichstentein" and "Emma" are richly coloured, but there are now such numbers, and so little varying from predecessors, that habits and other characteristics must be also considered before we can venture to say that this or that is an acquisition.

PYRAMIDAL FRUIT TREES (*A. A.*).—You may see them in first-class condition at Messrs. Rivers's Nursery, Sawbridgeworth, Herts.

POINSETTIA (*A. M. G.*).—You can obtain plants of any florist who advertises in our columns.

ORCHARD-HOUSE (*A Subscriber*).—Your walled angle will answer for an orchard-house. For Vines, it would have been better if the sun had continued longer on the house. We advise planting the Vines inside. A small stove would make such a house more generally serviceable.

PEAS (*C. P.*).—We have lost your address, or would forward to you a parcel intended for you, which we have just received.

MUSHROOM CULTURE (*A. D.*).—In "Doings of the Week" and elsewhere you will find several modes of cultivating Mushrooms successfully, and each of them will answer if carried out. From what you state you have done quite right in making up a bed about a foot deep of horse-droppings alone, but only making the bed by adding 2 inches at a time, and beating well as you went along. If a week or more passed between these additions your bed would never heat violently, and this would save the strength of your manure for the Mushrooms. You then add half an inch of soil—spawn, we presume, in the soil, and then add 1 inch more soil, beat down, water, smooth as often described, and cover with a little hay. The mode will do very well provided the suitable degree of heat is secured; at the time of spawning and afterwards the bed should be little over 80°, and the atmosphere of the place from 55° to 60°. We would have preferred placing the spawn in the dung instead of in the soil; but in either case it would find its way to the dung. In such good material we often add about one-third of lumpy, fibry, dry soil in making the beds; but when the dung is made from poor litter we use less soil in it. If you secure the proper heat we feel sure you will obtain plenty of Mushrooms.

LAWN RENOVATING (*F. E. M.*).—You should at once cover the lawn with rich soil, having previously raked it well with an iron rake. The soil should be put on one-quarter to half an inch thick, after the first rain it should be again raked well, and when dry the following mixture may be sown:—Festuca durinscula, 6 lbs.; Festuca ovina, 2 lbs.; Cynosurus cristatus, 6 lbs.; Poa nemoralis, 2 lbs.; Trifolium repens, 4 lbs.; Lotus corniculatus minor, 1 lb. Roll the ground well after sowing. The lawn should not be mown or rolled for at least a fortnight after sowing. The seeds may be had of any of the principal seedsmen.

WHITE SCALE ON PINE PLANTS (*A Subscriber*).—The powder to which you allude will not injure the plants if dusted into the heart of the young leaves, unless there be water lodging there. The plants should be dry before dusting with the powder, and it should not be wetted for twenty-four hours afterwards.

GUZMANNIA PICTA CULTURE (*Idem*).—Its treatment does not differ from that of stove plants generally, thriving as it does in a compost of turfy loam, peat, and leaf mould in equal parts, with one-sixth pieces of charcoal not larger than a hazel nut, the dust being sifted out, and a like proportion of silver sand. Good drainage is essential, and the soil should not be sifted but chopped, broken, and make fine with a spade. Water should be sparingly given after potting until the roots are working in the fresh soil, and when growing freely water should be supplied more liberally; and with a moist atmosphere and a moderate amount of air, the plant will grow freely. At night a temperature of 65°, and by day of from 75° to 90°, suits it during the summer.

TRANSPLANTING HOLLIES AND YEWS (*E. M.*).—You could not have a better time than the present for removing Holly and Yew trees about 6 feet high. The trees being dug round 2 feet from the stem, move them with as much soil as will adhere to the roots, and preserve as many of these as possible. Make a hole large enough to admit the roots without cramping or turning up their points against the sides of the hole, and spread out the roots carefully, placing some fine soil beneath, over, and around them. Do not plant too deeply, and after planting give a good watering. You may plant at the end of September, which is probably as good a time as any for planting evergreen shrubs.

PLANTING LAURELS ON A BANK (*Idem*).—The best time to plant Laurels on a bank or elsewhere, is from the third week in September to the middle of November, and the most suitable size of plant are those from 2½ to 3 feet in height; but the smaller they are the more certain are they of growing. They should be allowed to make a season's growth and should then be pegged down.

YELLOW-BERRIED HOLLY SOWING (*A Young Gardener*).—You may sow the berries now, or defer doing so until autumn, keeping them in the "rot" heap during summer. Sow them early in October. They will grow next year whether you sow them now or defer doing so until autumn.

MOVING CROCUS BULBS (*A Constant Reader*).—Taking up Crocus bulbs to make room for bedding plants is a bad practice and wholly unnecessary, for the Crocuses being in rows may remain, and the bedding plants be planted between them. The Crocus foliage may be removed when it decays, and it does not remain so long as to detract from the beauty of the bedding plants. You may remove the Crocuses, taking them up with a ball, and replant them in an open situation. They may remain in their new position until autumn, and may then be removed to the flower-beds and borders. The best plan is to leave them in the beds, and not disturb or replant them oftener than once in three years, and then take them up and replant on the same day.

PHOTINIA SERRULATA PROPAGATING (*F. G.*).—It is propagated from layers and cuttings. Layering may be done now, and the plants will be well rooted by autumn. The cuttings may be put in towards the end of summer in sand in a shady place under a hand-glass, or they will root more quickly if placed in a mild hotbed the same as for Rose cuttings.

BROCCOLI FOR SPRING AND EARLY CABBAGES (*A Young Beginner*).—Dilcock's Bride and Elletson's Mammoth will suit you in Broccoli for market purposes, and Cattell's Reliance and Battersea or Pulham Cabbages will suit you; but if you want a very early Cabbage, Atkins's Matchless, of which the Messrs. Veitch have an improved variety, is the earliest and best.

Hardiness of Shrubs (*F. G.*).—Rottlera japonica and Cæsalpina japonica are not more hardy than that they will do against walls in warm situations, or mild localities, having protection in winter. Stephania hernandifolia is a greenhouse plant or shrub; Chamæbatia foliosa and Embothrium coccineum are hardy in sheltered situations, but do best against a wall with a south or south-west aspect, and the same may be said of Pterostyrax hispidum, which is, if anything, more hardy.

Slugs and Woodlice in Fernery (*Pteris*).—Slugs are best caught by searching for them at night with a lantern. Woodlice are not easily caught. Their numbers may be considerably diminished by placing a boiled Potato in a little hay at the bottom of a flower-pot, and laying the pot on its side near their haunts at night. In the morning shake the woodlice out of the hay into boiling water. A number of Potatoes may be cut through the middle, the inside scooped out a little, and the pieces placed at night, hollow side downwards, near the haunts of the woodlice. In the morning the insects will be found secreted under the Potatoes and may easily be destroyed in boiling water. These traps will last a long time. For slugs, fresh Cabbage leaves may be laid at night near the plants eaten, and early in the morning the slugs may be found secreted under them. The leaves should be replaced every night by fresh.

Temperature of Fernery (*Idem*).—For your temperate fernery you will require heat when requisite to maintain the temperature at 45° at night, and this will be necessary from September to May. From September to March you will employ fire to maintain a temperature of 45° at night, though the thermometer may sink on very frosty nights to 40°; and from February to May the temperature at night should not be less than 45°, or from that to 50°. The day temperature will be regulated by the weather.

Lawn Covered with Lichen (*E. M.*).—Have the lawn well raked with an iron rake, drawing it backwards and forwards, and this being done two or three times the lawn should be covered with rich compost or manure reduced to mould, and again well raked. The soil or manure may be put on to the depth of a quarter or half an inch, then sow Festuca dumetosa, 6 lbs.; Cynosurus cristatus, 6 lbs.; Poa nemoralis, 2 lbs., and Trifolium repens, 4 lbs., and well roll afterwards. The quantity is for an acre.

Portulaca Culture (*J. T. B.*).—The culture of these handsome half-hardy annuals is very simple, but they must have a warm, sunny situation and a light, dry soil. The seed should be sown in pots or pans in a compost of light loam and peat in equal parts, and one-third of the compost should be brick and lime rubbish or gravel. The pans or pots should be well drained. Being placed in a mild hotbed water should be sparingly given, and only when necessary, then enough to run through the soil. When the seedlings are about an inch high remove them to a greenhouse or frame, and in June plant them out on ledges of rockwork, in rustic baskets, or in a sunny, warm situation, giving them to grow in at least a foot of the soil recommended for sowing, and if a foot of gravel or brick rubbish is placed under that all the better, as they flourish in a light, well-drained soil, on shallow soil on ledges of rocks, and on dry, well-drained slopes having a southern exposure.

Garden Netting (*G. E. J.*).—The netting which you mention is worth 9*d.* per lineal yard, or 3*d.* per square yard when the maker finds his own twine, and the netting is tanned to preserve it from the weather. For the size of net you name the maker should have 6*d.* per lineal yard, or 20*s.* The mesh you name is much too wide for Strawberries; it should not exceed three-quarters of an inch, and the price for that is 1*s.* 3*d.* per lineal yard of the width you name. Unless you have nets at some distance from the Strawberries the birds will peck the fruit through the large meshes.

Strawberries Going Blind (*A Gardener*).—The principal reason of their going blind is the roots being injured by exposure of the pots to frost, and another very potent reason is the immature condition of the crowns, and their being forced too highly at the commencement, whilst with a pot full of roots, the crowns well matured in autumn, and a light, airy situation, they are seldom blind unless the heat is excessive; that you name is quite high enough for them by or before they come into flower. You cannot give them too much air.

Enanthemum nubaovenium Culture (*Idem*).—It grows freely in a compost of turfy peat, loam, and leaf mould in equal parts, with a free admixture of sand. It should be potted now and have good drainage. Its treatment is not different from that of stove plants generally. We cannot make out the name of the other plant about which you inquire.

Cutting down Furze (*Jos. Templar*).—If you cut the Furze bushes now close to the ground they will shoot from the bottom unless very old, when some of them may die off.

Glands on Peach-Tree Leaves (*H. H.*).—The glands are on the leaf-stalks, near the base of the leaf.

Guano Liquid Manure (*Cheltenham*).—Half an ounce of guano to a gallon of water is quite enough for potted plants. One ounce to the same quantity of water may be employed to border plants. There is nothing surprising in the statement about the Cyclamen seedlings, if the cultivation mentioned by "H. C." is adopted.

Names of Plants (*D. Boote*).—Berberis aquifolium and Arabis verna. We cannot venture to state the heights, &c., of Phloxes. (*F. E. H.*).—The two are identical. Doodia caudata is the correct name. (*J. H. C.*).—1, Dendrobium primulinum; 2, Goniophlebium appendiculatum; 3, Asplenium diversifolium; 4, A. Belangeri; 5, Hypolepis anthriscifolia; 6, We do not recognise it, send again when in flower. (*Market Drayton*).—Probably Saponaria calabrica; but we cannot be certain from such specimens.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 16th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

VULTURE HOCKS IN BRAHMA POOTRAS.

In the discussion of this and of many other poultry matters, it appears to me that there has been a grievous want of that candid disposition to allow fair and proper weight to opposite views, which can alone lead to really satisfactory conclusions; and in approaching it myself I fear that I may meet the proverbial fate of those who interfere between husband and wife, and draw upon myself the hostility of each party, since I cannot altogether side with either, but I shall endeavour, whilst freely expressing my own opinions, to give fair play to both sides.

Those who contend that the recent crusade against vulture hocks is altogether an innovation, are certainly wrong in point of fact: for although only lately so rigidly disqualified, they have always been looked upon with disfavour at first-class shows, and considered as decided blemishes in otherwise good birds. Indeed, even now, I scarcely know of any who profess to admire them for their own sake, apart from their assumed connection with heavy leg-feathering; and I did, in fact, believe there were none such, until a few days ago I found I was wrong, and that there were breeders who actually admired the vulture hock *per se*. Neither can I by any means admit, as some would insist, that we must choose between vulture hocks and naked joints with comparatively bare shanks below them. If it were so, I would, indeed, ten times rather put up with the vulture hock. It will, however, I suppose, be granted that White Cochins are even more prone to the blemish under discussion than Brahmas—perhaps, indeed, more so than any other fowl we have; yet I appeal to all who can remember when Mrs. Herbert still exhibited, whether she did not always show birds magnificently feathered, but quite free from vulture hock? That this result was not due to trimming I am certain. Coming back to Brahmas, it will again be confessed that Mr. Boyle usually manages to show birds with splendid leg-feathering; yet there are never many vulture-hocked chickens in his yard, and those few so slightly so that they would probably pass muster in a pen. I need not pursue the argument further, only I repeat that since vulture hocks have always been more or less discouraged, and still well-feathered birds have been bred and shown for many years, we can surely breed good birds without them now.

Still it is an unquestionable fact that, connected with the recent decisions, we have of late had a great increase of naked-hocked and bare-legged birds. One reason of this, as I have before remarked, is the Dorking cross, which is just now more than usually prevalent in many Brahma strains, and upon which I need not remark further, as I have fully treated of it elsewhere. But the principal cause certainly is, that many exhibitors have what can only be called such a blind and senseless fear of the vulture hock, that they breed from their barest-legged birds rather than run the least risk of it. They recoil in terror from the idea of breeding from a cock whose hocks are only (as they ought to be), nicely covered, and rather than incur the very slightest chance of the dreaded fault choose birds whose legs are as naked as Adam's. Such will

reap the legitimate fruits of their folly, which ought not in strict fairness to be charged as a necessary result of recent decisions, though I must say that the eminent "professional judge" who informed "FALCON" that he always looked with suspicion even on "heavily feathered legs," did his share towarda causing the evil.

It cannot be too strongly insisted upon that the hock of every Cochin or Brahma ought to be well covered with soft feathers, nicely curled round and hiding the joint. This is not vulture hock, which consists of *stiff* and straight feathers projecting over the joint so as to form a distinct spur upon the limb; and I must say that if judges in general come to share the feeling of the "professional judge" already alluded to, whose name I do not know, and discountenance what ought rather to be insisted upon as the only correct feathering, we shall soon be all wishing to see hocks as large aa my hand, rather than what we shall see.

It will be seen that I am no friend to the vulture hock; yet there has been a most uncommon amount of incorrect assertion rashly made upon the other side. For instance, it has been said in these pages by "one of our ablest judges," whose name again I do not know, that vulture hock is altogether a recent introduction, perpetuated by "some unhappy wight" who ought to have "stamped it out," but did not! Now it has again and again been stated upon unquestionable authority that some of the earliest importations of Cochins contained vulture-hocked birds, and I am able to assert in the most positive manner that the greater number of the really Dark Brahma cocks imported from America were also very much vulture-hocked, the feathers in some nearly sweeping the ground. Neither can vulture hock be "stamped out" so readily as some would have us believe. Discouraged and kept under control it may be, and I think, for æsthetic reasons, should be, without any detriment to the breed; but I am satisfied it can never be absolutely exterminated, except at the price of losing good leg-feathering, for in every well-feathered strain the vulture hock *will* appear from time to time; and although, as ought to be the case, the birds thus furnished may be only one or two in a year, it is singularly probable that those few will be the largest, strongest, and best-shaped birds of the whole. This arises simply from the fact, that the cause of the vulture hock is unusual strength and vigour in the glands which nourish the plumage, leading to luxuriant feathering; just as strong men usually have more and coarser hair than weaker ones. Such birds, therefore, in everything save the condemned feature, are the most perfect types of the breed, and often the very best to breed from, especially when crossing into a weakly, small, or badly-feathered strain; though it should be noted, that whilst such a cross will often throw beautifully and quite correctly feathered chickens, the usual result is either the bare shanks of one parent or the vulture hock of the other.

Now, I hold it as a sound principle that any feature which is peculiarly apt to occur in birds which are otherwise the very best type of a breed, and in many respects the most desirable to breed from, cannot, without injury to that type, be absolutely disqualified, as is the case now. If such an inexorable rule be laid down, the result will be, and now is, that the majority of breeders will make any sacrifice of other points rather than run the slightest risk of the fatal disqualification. That it need not be so I have shown, but that it is so any one may see; and I have now somewhere in my possession a note from one of the most celebrated and accomplished poultry-breeders in England, who ought to know better, remarking that "vulture hocks being now disqualified, we have been compelled to fall back for breeding upon the scantily-feathered birds." I deny that the inference is correct, but it is, unfortunately, general.

On the whole, therefore, I would strongly urge that the old wording of the "Standard" should be restored as the law of our poultry judging upon this point—in other terms, that vulture hocks be considered "objectionable, but *not* a disqualification;" to be discouraged as an unsightly blemish, but not to put a fine bird at once and absolutely out of court. There are certainly one or two mistakes in that useful publication, "long necks" in Brahmas being one; but, on the whole, its compilers knew what they were about; and I think the restitution of their original dictum, while it would be sufficient to keep the vulture hock under control, would meet all the real necessities of the case and the wishes of nearly all practical breeders.

It is high time this subject should be seriously reconsidered, calmly and impartially, instead of in the partisan spirit which has hitherto so much prevailed. That the rule as it stands has done great harm cannot be questioned; and that such evil can be shown to be unnecessary, does not mend it as an unfortunate fact. That the views here expressed will please the ultras of either school it may be folly to expect; but they are the result of an anxious desire to form a correct judgment upon this vexed question, and I venture to ask for them the candid consideration of our poultry judges.—NEMO.

[Without any reservation we record as our opinion, that making the vulture hock either in Cochin-Chinas or Brahma Pootras a disqualification is a great mistake. Vulture hocks are not only usual developments in these varieties, but are so frequently borne by strong, well-developed birds, that we might venture to say that vulture hocks are rarely if ever found on weakly birds.

Tastes vary, and despite "NEMO'S" incredulity, we acknowledge ourselves admirers of the vulture hock *per se*. This, however, does not influence our judgment; and if the majority of the breeders prefer birds without such hocks let them be discouraged, but do not anathematise them. If a pen of Brahma Pootras is superior to all its competitors in other points, do not act so unjustly and so unwisely as to disqualify it on account of having vulture hocks. The absence of such hocks is not, like the fifth toe of the Dorking, a mark of purity of breed.—EDS.]

BRAHMA POOTRAS.

I DO not know whether I am the correspondent of the old "Poultry Chronicle" to whom "Y. B. A. Z." refers in your last Number, page 267, but I made experiments some years ago, which I recorded in that Journal at the time, for the purpose of obtaining the pea-comb, which was alleged to be peculiar to the Brahma. I "raised" several chickens from a Malay hen and a Cochin cock, and obtained by that cross the true pea-comb, and the cruel expression of countenance too; and I am inclined to think that this is a remnant of the Malay cross whenever seen, or at least is generally so. I have never from the first hesitated to believe the account given in an American poultry-book—Bennett's, I think it is—of the origin of this variety of fowls. I remember M. Garbonati's fowls well. I also recollect the wonderful pair bought by Mr. H. D. Davies for £105. Up to the time these were shown, light birds used to obtain prizes commonly; after they put in an appearance nothing but dark birds went down with the judges. I also recollect seeing the progeny of these birds at Mr. Davies's; a more mongrel lot cannot be conceived—pea-combed and single-combed, some almost white, others almost black, it was impossible to pick out two alike. I believe that the breed has been made, as the Sebright and Game Bantams have been within a few years, and the avowed difficulty which breeders find in keeping the colour pure and getting rid of buff feathers corroborates my belief.—P.

RAILWAY EXTORTION AT LORD TREDEGAR'S POULTRY SHOW.

AT this Show, held at the close of last year, I found the charges made, especially for the homeward journey, shamefully excessive, so much so as to determine me never again to exhibit there unless the Great Western Railway relieved exhibitors from this unfair charge. I determined, therefore, to see how far my fellow exhibitors shared my feelings. Accordingly, to ascertain their sentiments, I made out a list of those that I fancied must have been victimised, adding their addresses, and headed this list with a few words to my fellow-sufferers, suggesting that we should endeavour to show the Committee of Lord Tredegar's Show that they must enforce some alteration, or we must decline entering any specimens; and I forwarded also with the list and my suggestions a memorial to the Committee, which I had already signed, for each exhibitor who pleased, to sign and forward to the next on the list, and in case of declining to sign still to forward the papers. During the past few days the memorial and its signatures have been returned to me, and by me duly forwarded to Mr. Palling, the Honorary Secretary.

There were, at the last Show at Newport, 253 entries; ninety-three of these were made by residents at Newport and in its immediate vicinity. Possibly this number is below the actual amount, as from the catalogue I may have omitted some, not knowing that the places were really local. There are also several exhibitors to whom the memorial was never sent,

simply because the chief ground of complaint being against the Great Western Railway, I gathered from their localities that they were fortunate enough to escape its tender mercies. These exhibitors are credited with between forty and forty-five entries.

Thirty exhibitors have signed the memorial; these exhibitors made one hundred entries. It follows from this, that of the one hundred and fifty entries out of Newport no less than one hundred entries were made by individuals who, in the matter of the railway charges, feel themselves to have been unfairly treated, and who have pledged themselves not to exhibit again at this Show unless some more satisfactory arrangement is made with the railway authorities. Of those to whom the memorial was forwarded only five or six exhibitors declined to sign. Amongst those who did sign are names most familiar in our prize-lists; indeed, in the actual prize-list of the Newport Exhibition twenty-seven out of the thirty signatures may be found; it cannot, therefore, be said that it has been signed only by disappointed exhibitors.

In conclusion, I must remind all those interested in getting up exhibitions, that this is with them a vital question. Quite in this light must Mr. Palling, the Honorary Secretary to the Newport Show, regard it, for a few days after the receipt of the memorial I had the following reply:—

"My Dear Sir,—Your favour with enclosures, dated 29th ult., reached me yesterday. I promise that no pains, influence, or argument that can be brought to bear shall be wanting in urging the Great Western Railway to accede to the most reasonable request of the memorial. They have been asked before and declined. I hope, however, we shall this year succeed, and be able to print the concession with the schedule.—Faithfully yours, J. G. Palling."

My advice to those who do get up exhibitions is simply this: Appeal to respective railways and say it is our intention to hold a show at such a date. The show, however, will be carried out only on condition of your reducing the rates of carriage of specimens. Now, if our dear old grandmother (for in spite of mistakes in judging and other matters, still we all like her), I say, if our dear old grandmother Birmingham would only just try this on—no reduction, no show of poultry, would she still be obliged to print that insult to all poultry exhibitors, that "all unsold specimens, except poultry, will be conveyed free on return journey?" We owe a great deal to Birmingham; we should be vastly more in her debt if she would try this plan, and in default of a successful answer carry out the threat. It is far from improbable that at Birmingham in 1868 we should have the railways offering a £20 cup and free carriage both ways.—Y. B. A. Z.

BREEDING GAME FOWLS.

In reference to "Newmarket's" remarks in No. 300, page 492, and in No. 302, page 33, I have to say, that breeding in-and-in too much is objectionable. I have invariably found the following method answer well. After the selection of your brood stock, if on due consideration you find the birds meet your approbation, put them early together so that they may become friendly one with the other. I would also keep the eggs of each hen separate and marked; by so doing you can distinguish which hen produces the most perfect progeny; indeed, some breeders are so particular that they will not allow more than one hen to each cock. Attention should be paid every day to prevent errors, and to see that your brood stock is not suffering from bad health, as deviations will occur be as particular as we will.

Should the produce meet my expectations, I would not retain the brood cock for more than four or five seasons; some breeders substitute another when he is three years old. I would then select a fine young cockerel, perfect in every respect, and breed from him and his two-year-old sisters, or from mother and son. This cross you might use to advantage for four or five years, and then substitute a fresh cross from some noted yard, but great caution ought to be used in the selection. Choose him with every essential property, otherwise you may undo all your previous care. I would then keep a cockerel from this cross and breed from him and my old hens; by this means I would not sacrifice the old blood. I should only adopt this method as a rule when my strain of brood fowls was as near perfection as good breeding could bring them. It is often the case that, notwithstanding every care in the introduction of a cross, the produce may be defective, and the defects difficult to eradicate, such as deformed backs, crooked breasts, and duck-foot.

With every respect for "Newmarket's" opinion, I must still adhere to what I previously expressed in regard to the form of tail. I think when a bird has a good neck, ample shoulders, and tapering behind, a neat whip-tail very much improves the contour, and gives a more graceful appearance. On the contrary, when a bird has a short cocked tail and the curve of the sickle feathers is short and quick, the tail has rather a broomy appearance and does not show the shoulders so finely. Light extremities I much admire, but I do not appreciate a tail that droops too much. Under excitement Game fowls will erect their tails more, and the attitude and general appearance will be more spirited. Some will also carry the tail in a very erect position when not under excitement; but I think this does not justify me in saying they are any deeper Game. I have had both kinds, but never found the cocked-tailed birds of greater courage, nor do I like them so well as the whip-tailed ones.

As regards spurred hens, I do not think the spurs produce more courage or improve the appearance of Game hens. Occasionally barndoor fowls will be found spurred, but I can see no special advantage in this. About thirty-five years ago my brother had two Game hens, one a Black and well spurred, the other a Spangle without spurs. These hens during the breeding season and when nursing their progeny would generally have their battles, and although the darker hen was the more powerful, she on several occasions had to succumb to the prowess of her more agile rival. The battles were of a determined nature, and the sufferings of these poor birds from loss of sight, swollen and skinless heads, must have been severe indeed. Numbers of cocks descended from both these hens were fought, and singular to say, those bred by the Spangled hen were better spurrers and superior fighters. The cocks from the dark hen weighed in fighting trim from 4 lbs. 12 ozs. to 6 lbs., and those from the Spangled hen from 4 lbs. to 5 lbs., and both were undoubted Game.

I think the weights in the mains of the present day are upon a higher scale than formerly. An old cocker has just informed me that several mains have been fought recently, and that the weights have been from 4 lbs. 6 ozs. up to 5 lbs. 14 ozs., indeed a few weeks ago some birds were fought at 8 lbs. He also told me that in Lancashire cocks are taken off their walks weighing 6 lbs. and fought at 5 lbs. The Shakebags or Duke of Leeds birds weighed 8 lbs. or 10 lbs., and were deep Game. The origin of this breed is not exactly known, but I should fancy the birds from their large size to be of foreign extraction. In "Sporting Annals" for November, 1827, I find that "Lieut.-Colonel Mordaunt," an ardent cocker, resolved to transport some English Game fowls to India, in order to test the courage of the foreigners in their own country. These birds had been described to him as being as bold, if not bolder, than ours, and of more strength. Lieut.-Colonel Mordaunt accompanied his cocks to India and saw them defeated.

Does "Newmarket" or any of your readers know anything of the Muscovite Black Game hen mentioned by Buffon? The large size which some, or a great portion of our Game fowls have attained is undoubtedly inherited from imported birds, and I think in some instances this cross has been indulged in too freely. Several birds which I noticed at the Halifax Show, held February 2nd, had a very stilted, gawky appearance; indeed, as I heard a gentleman remark, they had too much daylight under them. The seemingly growing propensity on the part of some breeders to exhibit such birds might be easily arrested if our leading judges would discard such ungainly specimens.

It is a pleasure to an experienced breeder to see his parent stock produce a clutch of chickens nearly equal in size, closeness, and shortness of feather, and free from any deviation in colour; also when grown to maturity for them to be well balanced in shape and contour. All the parties whom "Newmarket" mentions exhibit good birds, but whether they breed or purchase them I cannot say. In my previous articles on Game fowls I omitted the name of a successful breeder, although not a prominent exhibitor. I allude to Mr. R. Scrimminger. I should think most breeders have been greatly indebted to his stock as a cross.—Yorkshire.

FOOD FOR CHICKENS.

An advertisement appeared on the 21st of last month from a person signing himself "A. Le Cheminant, Foulon Vale, Guernsey," recommending food for chicks; the method of preparing it would be sent for seven stamps. I sent them on the

24th, and up to this time have received no reply. I again wrote for either stamps or recipe, but to no effect.—A Weekly Subscriber.

WHARFEDALE AGRICULTURAL SOCIETY'S POULTRY SHOW.

The sixty-ninth annual Exhibition of the Wharfedale Agricultural Society took place at Otley on the 12th inst. This is perhaps the eldest Society of the kind in existence, and has enjoyed an uninterrupted series of successes since its establishment. Being the first show of the kind in the season in Yorkshire, it is generally well attended, and this occasion was no exception; and had it not been for the unexpected and unfortunate strike of enginemen on the North-Eastern line, there is no doubt but the good old town of Otley would have witnessed the largest concourse of people that had ever been seen within its precincts. As it was, the whole of the traffic on this line was suspended, which proved a great hindrance to the conveyance of stock and poultry; and had it not been for the extreme courtesy of the Honorary Secretary, Mr. Lee, in withholding the Judges from their labours till a late hour, many would have had to suffer disappointment who can now exult in well-won honours.

In *Spanish* there were but three entries, the cockerel in the first-prize pen and the pullet in the second being gems of their kind. *Dorkings* had a large entry, some large well-framed birds being exhibited. Two magnificent pens of *Polands* were shown by the same exhibiter, the first award going to Silver and the second to Golden. The class for Red *Game* was large, and some excellent birds were shown, especially Brown Reds, which colour took both prizes, Mr. Aykroyd winning first with a pair of birds which may be said to be perfect; this pen also took the silver cup given for the best pen of Game of any variety. A good pen of Duckwings was first in Greys and Blues; and in the Variety class the first prize went to Red Piles, no others in these two classes being worthy of notice. The Golden-spangles as a class did not look well, though two excellent hens were shown by Messrs. Ashton and J. Dixon. The winning pens in the rest of the *Hamburgh* classes were as good as could be wished for, the first-prize pen of Silver-spangles belonging to Mr. Beldon standing quite prominent—being, in fact, one of the most striking and perfect pens of birds that can be conceived. The silvery whiteness and almost transparency of the neck and tail hackle of the cock enabled the marking of the plumage to be seen to great advantage. The cup for the best pen, Game excepted, was awarded to these birds, and they were sold very readily at the close of the Show. *Game Bantams* were but poor, but some very excellent Blacks and Whites were exhibited, also Gold and Silver-laced.

There were two pens of good large Rouen *Ducks*, but the rest were poor. Aylesburys were a wretched class. Mr. Dixon was first in the Variety class with a lovely pen of Bahama Ducks; and the pen of Carolinas shown by Mr. Harrison were very fine.

There was a moderate entry of *Pigeons*, Mr. Beldon being the principal winner.

Spanish.—First, H. Beldon, Gilstead, Bingley. Second, J Thresh, Manchester Road, Bradford. Highly Commended, J. Dyson, Wetherby.

Dorkings.—First, H Beldon. Second, J. White, Warlaby, Northallerton. Highly Commended, T. Mason, Green Hammerton. Commended, W. M. Spence, Weston, near Otley; J. White; W. Edmondson, Highfield, Denton, near Otley.

Polands.—First and Second, H. Beldon.

Game (Red).—Cup, E. Aykroyd, Girlington Road, near Bradford. Second, J. Hodgson, Bowling Old Lane, Bradford. Highly Commended, H. Beldon. Commended, J. Hudson, Baildon Green; J. W. Other, Leyburn, near Bedale; T. Mason.

Game (Grey or Blue).—First, W. Fell, Adwalton, near Leeds (Duckwing). Second, Miss Deighton, Hawksworth, near Otley.

Game (Any other variety).—First, H. C. Mason, Drighlington, near Leeds (Pile). Second, J. W. Other.

Hamburghs (Golden-spangled).—First, S. & R. Ashton, Mottram, Cheshire. Second, J. Dixon, North Park, Clayton, Bradford. Highly Commended, H. Beldon; W. Barstow, Bingley.

Hamburghs (Silver-spangled).—Cup and Second, H. Beldon. Highly Commended, J. A. Taylor, Manchester. Commended, J. Dixon.

Hamburghs (Golden-pencilled).—First and Second, H. Beldon, Bingley. Highly Commended, J. Dixon, Bradford; W. J. Harker.

Hamburghs (Silver-pencilled).—First and Second, H. Beldon. Commended, R. Longbottom, Bingley.

Game Bantams.—First, J. R. Jessop, Hull. Second, Moody & Cooper, Otley. Highly Commended, R. Charlesworth; J. M. Jolley.

Bantams (Black).—First, H. Beldon. Second, W. A. Taylor, Manchester. Highly Commended, J. R. Jessop.

Bantams (White).—First, J. R. Jessop. Highly Commended, W. Bentley, Fairweather Green, Bradford; F. D. Johnson, Birmingham.

Bantams (Any other variety).—First, T C. Harrison, Beverley Road, Hull. Second, S. & R. Ashton. Highly Commended, H. Beldon:

Any Other Distinct Breed.—First, H. Beldon (Cochins). Second, J. Dixon (Cochin Partridge). Extra Second, W. A. Taylor (Buff Cochins). Highly Commended, H. Beldon (Brahmas). Commended, W. Bentley (Andalusian).

Ducks (Rouen).—First, J. Ward, Drighlington, near Leeds. Second, J. Dixon. Highly Commended, H. Beldon; W. R. Renton, Riffa, near Otley; A. Fawkes, Farnley Hall, near Otley.

Ducks (Aylesbury).—First, Miss Newsome, Whack House, Yeadon. Second, A. Duncan, Westbourne Lodge, Otley.

Ducks (Any other variety).—First, J. Dixon. Second, T. C. Harrison Highly Commended, H. Beldon (Calls). Commended, J. W. Scriven, Throstle Nest, Otley.

PIGEONS.

Tumblers (Short-faced).—First, H. Beldon. Highly Commended, A. & B. B. Laycock, Woodville, Keighley.

Tumblers (Common).—First, H Beldon. Highly Commended, H. Endeacott, Hunslet Road, Leeds; G. Stanhope, jun., Eccleshill.

Fantails.—First, H. Beldon. Highly Commended, W. C. Dawson, Weston Hall, Otley. Commended, A. & B. B. Laycock.

Pouters.—First, H. Beldon. Highly Commended, J. Mason. Commended, H. Endeacott.

Barbs.—First, H. Beldon. Highly Commended, A. & B. B. Laycock; T. L. Ritchie, Otley. Commended, J. W. Scriven.

Owls.—First, H. Beldon. Highly Commended, A. & B. B. Laycock. Commended, J. W. Scriven.

Carriers.—First, H. Beldon. Highly Commended, G. Stanhope, jun. Commended, H. Endeacott.

Turbits.—First, H. Beldon. Highly Commended, H Endeacott.

Jacobins.—First, H. Beldon. Highly Commended, H Endeacott.

Any Other Variety.—First, W. C. Dawson (Swallows). Highly Commended, H. Beldon; J. Mason. Commended, G. Stanhope, jun.

Judges.—Mr. E. Hutton, Pudsey, and Mr. C. Dearlove.

CITY COLUMBARIAN SOCIETY.

A meeting of the City Columbarian Society took place on Thursday last at the Crown and Cushion Tavern, London Wall, for the purpose of electing officers of the Society for the ensuing year, when G. Chapman, Esq., was re-elected President; R. Wingfield, Esq., as Vice-President; Messrs. Plaskett, Gillett, and Goode as Auditors; and Mr. J. Ford as Secretary and Treasurer.

It may not be generally known to your readers that the above Society was formed about twenty-five years ago, and its members meet at the above tavern every alternate Thursday (in the season), for the purpose of encouraging the breed and discussing the merits of that most interesting of home pets, the Pigeon. The value of some of the choice specimens will be understood from the fact that they have changed hands in the above rooms at five, ten, and even twenty guineas the pair!

Gentlemen who take an interest in the above will find the Secretary always willing to give them any information they may require.—Columbarian.

PLURALITY OF QUEENS IN A HIVE.

Although Mr. Lowe's communication which appeared in pages 187-8, is exceedingly interesting, especially that portion of it which refers to the plurality of queens, it can scarcely fail to occur to many of your readers, that whilst he discredits the evidence of all other observers, he himself bears witness to the occurrence of the most singular anomalies. Although perfectly satisfied there is nothing Munchausen-like in his statement, I have yet grave doubts as to whether his observations have really been accurately made, and whether his inferences are truly in accordance with facts. I do not think I have ever said anything from which your correspondent could fairly infer my opinion to be that it is not an uncommon occurrence for two queens to be in a hive at one time. I stated only what had come under my direct observation. Nevertheless, there are times when a plurality of queens is more common than at others. For example, if there has been a cessation of labour for some time previous to removal to the heather, and subsequently fine weather sets in under certain circumstances, and for certain reasons, there may be found a plurality of queens.

I am not now, however, disposed to enter into the discussion, or to give a detailed account of how and under what circumstances a plurality of queens is to be found, but will confine myself to asking a few questions in reference to queens living for three weeks together, which is so contrary to the nature of bees, that I can scarcely credit the accuracy of the observations which have been made by Mr. Lowe.

Admitting, then, that an old and a young queen are to be found in one hive at the same time, has Mr. Lowe never seen that sometimes both young and old were dethroned? New laid eggs being in the hive at the time young queens were again attempted to be brought forward, but only to be destroyed, and that at the last moment a few worms were chosen, and successfully reared. Has this never been observed by him? And, again, has he ever witnessed a case in which the old queen was dethroned just at the birth of young princesses, and during the fight for the crown one young one has taken flight and returned impregnated? And if he has observed whether she was well received, and succeeded in establishing herself as head of

the hive; or if she was seized and forced to resign, when another more successful was allowed to reign? If apiarians in general would pay some attention to hives under these circumstances, it might in some cases assist in clearing up a mystery, or what appears to be one, and might also throw some light on cases of a supposed second impregnation.—A Lanarkshire Bee-keeper.

HOW TO EMPTY HONEYCOMBS.

The bee papers of Germany and America are filled with accounts of a discovery by an Italian apiarian, of a method of emptying combs of honey without injuring them. The process is exceedingly simple and consists only in slicing off the caps of the cells, and then causing the combs to revolve on the periphery of a wheel or cylinder, which empties one side of honey—then the other side is turned and emptied. Liquids upon bodies which are whirled or revolved tend to fly off by what is called centrifugal force. In this case the revolution is so graduated that only the honey flies off, and dead bees, bee-bread, &c., remain behind, so that not only is the comb saved, but the honey is purer and better than that strained. The temperature requisite to success, is about 80° Fahrenheit, which is gained in a warm room or on a sunny day.

The value of this invention may be the better appreciated, when it is known that it requires the consumption by the bees, of 15 to 20 lbs. of honey (estimates vary), to make 1 lb. of wax, consequently, that the comb requires for its construction the use of just about as much honey as it will contain when filled. It may be found that in the economy of bee life, it is essential for the bees to make or excrete a certain amount of wax in order to remain in good health; but this is hardly probable, for it has long been the practice of bee-keepers to save empty or partly filled combs with scrupulous care, and give them to the bees, and no bad results have ever been noticed.—(*American Agriculturist.*)

FRUIT ESSENCES.

The products known under the name of Fruit Essences, are alcoholic solutions of different ethers, to which are sometimes added certain acids, or certain natural essences. Glycerine is found in all; it appears to blend the different odours, and to harmonise them. It is necessary to state, that the alcohol used, as well as all the other substances, must be chemically pure.

Each column represents the measures to be added to 100 of the same measure of alcohol.

Names of the Essences.	Chloroform.	Nitric Ether.	Aldehyde.	Acetate of Ethyl.	Formiate of Ethyl.	Butyrate of Ethyl.	Valerianate of Ethyl.	Benzoate of Ethyl.	Œnanthylate of Ethyl.	Essence of Persicot. NON-RESISTING BEES.

I last summer paid a visit to a friend who had a number of hives, of which I purchased several, and had them prepared for removal, when an inspection of the rest of his stock was invited. He remarked that there was one good hive, as it had a honey-box, the contents of which weighed exactly 25 lbs., but there was not much in the rest of the four octagon boxes which the stock inhabited, he having a few days since removed the super, but had replaced it again for the purpose of "no to be fashed feeding," remarking at the same time that for three or four hours after manipulation the other bees robbed it, but had since stopped. Now the fact is that it had been entirely robbed out, and had never made any resistance. This was the more singular as it consisted of two strong swarms joined, and the stranger bees had actually to pass through the three lower boxes ere they reached the super. My friend wondered at it, and asked my opinion. "My experience," I said, "with bees is that to stranger bees, as well as to man, they become docile when well filled with honey. When you removed the super the tenants filled themselves, and would not offer any resistance." I then advised him, when bees were disposed to rob, to remove all supers at dusk, as the bees would then have full time to disgorge themselves, and be ready for defence by the next morning. There are also times, I remarked, when food ought at first to be gradually given, as bees sometimes fill themselves and kept themselves filled as if they were secreting wax, and then they offer little resistance to strangers. That a sudden jerk or even a slight inspection sometimes caused them to fill themselves, and brought them into imminent peril of being robbed.—A Lanarkshire Bee-keeper.

OUR LETTER BOX.

Wioton Poultry Show (*B. W. C.*).—We cannot notice other journalists' mistakes. The reference was evidently to Hamburghs.

Hens Laying (*W. A. O.*).—You can only ascertain by watching them.

Books (*Dickey Bird*).—Mr. Brent's "Canary and Other Song Birds" includes other songsters besides the Canary You can have it free by post from our office if you enclose twenty stamps with your address. "The Pigeon Book" relates to Pigeons only. You can have it sent for twenty stamps. "The Poultry Book for the Many" you can have for seven postage stamps.

Daily Management (*L. T. B.*).—What management do you refer to?

Spanish Fowls (*J. H.*).—We never heard of Spanish fowls being sold for 30*s.* per dozen, and that they are not to be had at that price is evidenced by your advertisement being unanswered.

Ulcers on Spanish Cock's Face (*T. J. P.*).—The red spots and the offensive discharge from same indicate, we fear, that ulceration which is considered incurable. We think it possible to cure it, and recommend you to apply acetate of iron once daily to the ulcers.

Work on Pigeons (*W. Massey*).—We cannot insert your communication. You only repeat more strongly what "Wiltshire Rector" stated.

Lapwings (*J. W. H.*).—We have no knowledge of the mode of catching them.

Parrot, a Feather-eater (*S. Burnett*).—Omit hempseed and bones from the bird's diet, and keep it on soaked bread and fruit, such as apple, figs, raisins, &c. Let the bird have a tepid bath every day, which is usually effected by allowing the bird access to a soup-plate full of water slightly warmed. If the bird avoids bathing pour the water over it through the rose of a watering pot.

Cock Canary Eating the Eggs (*C. C.*).—The best advice we can give is contained in the following extract from Brent's "Canary and Other Song Birds:"—"Some fanciers remove the eggs as laid, substituting a bone or ivory egg till all are laid, keeping the eggs in a cool and safe place, and returning them when the hen ceases to lay. This is very necessary if the cock is inclined to be mischievous, in which case he should be removed, or placed in the compartment of the cage when the eggs are put into the nest. It has also the advantage of hatching all the young at one time." You can have the book free by post from our office, if you enclose twenty postage stamps with your address.

Payne's Hives (*Rev. W. V. W.*).—They may be purchased of Messrs. Neighbour & Sons, Regent Street, or of Mr. Pettitt, Dover.

Propagating Ligurians (*Q.*).—The possession of moveable comb hives is so essential to the artificial propagation of Ligurian bees, that my instructions were based upon the supposition that any apiarian who contemplates following them will first avail himself of the advantages offered by hives of this description.—A Devonshire Bee-keeper.

Insect Preying on the Black Currant (*A Lanarkshire Bee-keeper.*)—We have submitted your sketch and description to an eminent naturalist, who fails to identify the insect. You had better send us a specimen or two by post enclosed in a quill for safe carriage.

Gold Fish.—A correspondent wishes for some information under the following circumstances:—"In the kitchen garden is a largish pond of good water, with a stream flowing through it. At various times, first of all about three years ago, there have been turned into it, about in all, three dozen of these fish. Only about seven now remain, and most of them have grown very large. I have not ascertained one instance of any being bred in the pond, and they gradually diminish. They cannot be stolen, for no one here could dispose of them. When first put in they were all gold colour; several turned white or silver. What is the cause of this? The ice on the pond is regularly broken in the winter. It is about 6 feet deep. There are a few trout in it, not large ones."—W. W. E. W.

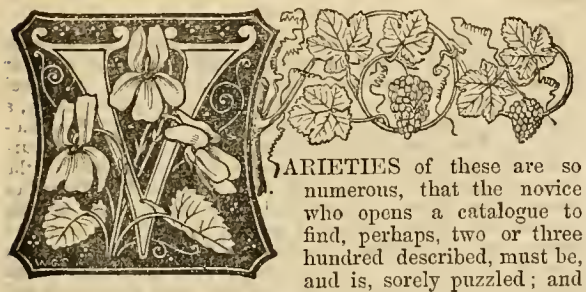
From observations taken near London during the last forty years, the average day temperature of the week is 60.4°; and its night temperature 37.2°. The greatest heat was 82°, on the 27th, 1865; and the lowest cold 18°, on the 29th, 1861. The greatest fall of rain was 1.40 inch.

BEDDING PELARGONIUMS.



VARIETIES of these are so numerous, that the novice who opens a catalogue to find, perhaps, two or three hundred described, must be, and is, sorely puzzled; and the numberless questions that are asked on this point surely indicate this perplexity. Before considering it, let us see what are our requirements. We must have profuse blooming: this is an essential. Many very fine varieties, fine as pot plants, are comparatively useless owing to their not possessing this quality; for it is of no use to have either a bed or ribbon with a few flowers, however fine, holding their heads up here and there—we must have a mass of rich and glowing colour. Then we must have, or at any rate we generally require, dwarfness and compactness of growth. Tom Thumb won his way into favour by these two qualities, and even now holds his place with many, notwithstanding the smallness of the trusses and the bad shape of the flowers. Then the variety ought to have fine large trusses; small trusses of some ten or twelve pips are not wanted. In the opinion of some it ought to have plain foliage where effect is to be produced by the colour of the flowers; for instance, where the scarlet is to make a contrast with yellow, anything of decided colour in the leaves must take away from the effect.

What Pelargonium in the scarlet-flowered class best fulfils the above conditions? For many years I found Attraction, *alias* Scarlet Perfection, to be the best; but, as I have before said, I think now that Editor, sent out by Mr. Bull, is by far the best in this way; its profuseness of bloom is very great, while the trusses are large, and the pips also large and good. Vivid, another good sort, is too gross in habit. Governor, with very fine trusses, is not free. Frogmore Scarlet is a good flower, somewhat in the style of Attraction. Clipper, with a very marked and decided horseshoe, is a noble flower, but I think hardly free enough in its flowering qualities. Glow is a very bright and lively flower.

Next, taking the rosy pink varieties, we have the old Christine, with its rivals Helen Lindsay and Rose Rendatler. As far as my judgment goes, it is fully equal to either of these, its chief fault being that it seeds so very freely that the seed-pods are often very unsightly. Wiltshire Lass, another flower in this style, came out only last year, and so I have not been able to speak much of its qualities as a bedder; for last season, I think, defied all attempts at fixing the value of any bedding plant. Beauté de Suresnes is a noble flower, but I fear hardly free enough in its flowering qualities.

Of lighter scarlets with a tinge of orange in them, Dr. Lindley is a valuable kind, having a well-shaped flower, a large truss, and being a tolerably free bloomer. Excellent is a good light scarlet flower, and very free; it makes a capital bed. Of the salmon-coloured varieties Madame Rendatler, Paul Labbé, and Prince of Hesse are about the best, and any of them will not fail to give satisfaction. They are not new, but as yet I have not seen any of the newer varieties, excepting, perhaps, Eugénie Mézard, which is very good. Lucius is a bright salmon rose, and made a very effective display at Battersea. There is a large number of the varieties in the Madame Rudersdorff style, which hardly, I think, come under the designation of bedding Pelargoniums: they are too delicate in their colouring for that purpose, though admirable for pot culture.

I am constrained to say as to whites, that not only have I as yet seen none to beat Madame Vaucher, but that I think it would be perfectly easy for any one who received an order for White Perfection, Madame Barillet, White Tom Thumb, &c., to execute it from plants of the old variety. Report speaks highly of a dwarf variety of Mr. Groom's, of Ipswich, called Floribundum Nanum, but of this we have yet to judge. After all, are white-flowering Pelargoniums of any use for bedding? They certainly are not if you want to have a white bed; and the colour is so soon dashed by the rain, that it is sure to look dingy if we have any bad weather.

Amongst the Variegated bedding Pelargoniums I take the Tricolors first; and here I must own that as yet nothing has come up to Mrs. Pollock as a bedder. It will not do in cold and wet soils and in damp situations; but wherever it is light and airy, and the soil either naturally rich and well-drained or made so, nothing can be more beautiful. It will take abundance of well-decomposed dung, and should be planted closer than many other kinds if an effective display is wanted. Others, such as Lady Cullum (Henderson), and Meteor (Saltmarsh & Son), bid fair to rival Mrs. Pollock; but as yet I cannot say, as they are hardly to be looked on as bedding plants at 21*s.* a-piece.

Among the Golden-leaved varieties I think Golden Fleece must bear away the palm; so any one who saw it at Battersea would be, I think, constrained to say. It is freer in its habit than Cloth of Gold, and has more of the golden colour than Golden Chain, which, indeed, is more of a golden-edged than golden-leaved variety.

Of Silver-edged varieties I have as yet seen nothing that surpasses Queen of Queens, Bijou, and Flower of Spring. The first of these has a very bright silvery edge, and the flowers are well-shaped and bright scarlet. Bijou has also scarlet flowers, is very free in its habit, and for strong soils perhaps a little too much so; while Flower of Spring is a beautifully compact-growing plant, with a well-defined silvery edge, and a bright pink well-shaped flower. Although there is a large number of other varieties, I know of none which as yet are to be preferred to the three named.

Of the Silver Tricolor-leaved varieties, I do not think any are suitable for bedding. Many of them, as Italia Unita, are very delicate in habit, and lose their distinguishing characteristic—the beautiful pink or crimson

zone when grown out of doors. As pot plants nothing can be more beautiful; but I am not now dwelling on pot plants, but on those suitable for bedding purposes.

It will be noticed that I have said nothing upon Nosegays. The truth is, I have not yet overcome my prejudice against them. I mean, however, this year to try a few, and see whether, when constantly under one's eye, the prejudice against them may not wear off. I am ready to admit the variety of shades of colour amongst them, shades as yet not obtained in the Zonal section; but I do not like their raggedness, nor do I see that they are more free in flowering or more enduring than the Zonal section.

I do not doubt that many will differ from me in the conclusions I have come to. I can only say that they have been formed on rather a wide acquaintance, and that, having seen the varieties in many places, those I have named seem to me, taking all the requisites into consideration, to be the best. Let us hope that a more favourable season than last will enable us to judge concerning many of the newer varieties, which as yet we have been unable to do.—D., *Deal.*

A CONTINUOUS SUPPLY OF CUCUMBERS.

Much has been said, and well said, about the cultivation of Cucumbers, their diseases, and their failures in the winter time. It is no easy matter under many circumstances, even with good appliances, to secure a regular supply at all seasons, especially in winter; the plants require careful tending at all times, and I have known many failures, even in spring and summer, when the means were limited.

I do not for a moment suppose that there is anything novel in what I am now advancing about the cultivation of Cucumbers in winter, but it may be useful to describe a method founded on long practice, and which has attained the object aimed at—namely, a supply all the year round, though I have not, like many of my more favoured brethren, a house specially devoted to the cultivation of Cucumbers. I have a fruiting Pine-stove heated on the Hamiltonian system; hot water flowing in cemented tanks or gutters, covered over with blue slates, supplying the bottom heat. The house is a lean-to, ventilated back and front with sliding doors, but there is no ventilation at the top. Along the back of the house is a path, and a tank or gutter runs parallel with it to give off a certain amount of top heat; over this tank is constructed a trough or box, and a space of about 9 inches is left from the top of the tank to the bottom of the trough or box, which forms the future Cucumber-bed. This receives bottom heat from the tank, as well as from the side of the bed in which the Pines are planted out. The place for the bed is about 20 inches deep, and the bottom is pierced with holes to permit the water to escape; these are covered with large hollow crocks, and the bottom with 4 inches deep of broken bricks or other rough material as drainage, a proper amount of which is very essential for the future well-doing of the plants. Above the drainage is placed about an inch of rough charcoal, and over it moss or some other covering.

We are situated near a river, and the soil being of a heavy retentive nature we are obliged to add to it many ingredients to keep it porous. For Cucumbers I form the compost as follows:—I procure the best turfy loam which is to be had, lay it up in a stack for some time previous to use, and to each bushel of this roughly broken I add half a peck of good sound leaf mould, one peck of thoroughly decomposed dung, half a peck of charcoal dust, a sprinkling of bone dust, a little soot, and a small quantity of river sand to keep the mass open. The whole being well incorporated together, I have a porous compost through which the water passes quickly. This, in my opinion, is one of the first steps to success.

The place and soil for the bed being ready, we put in an upright rod, and fasten it to the rafter to tie the plants to as they advance in growth. We allow the plants a certain space to each by placing a partition between them, so that in case of need a plant can be removed without interfering with its neighbour. This being done, the soil is put into as many spaces as are required, placing the roughest portion of the compost at the bottom, and making the soil about 10 inches deep, so as to leave room for top-dressing with rich compost when the plants require it. The bed is allowed to remain a few days before planting, in order to acquire a genial temperature; and when this is the case the plants, which have been previously prepared, are planted about the end of September. After planting, a gentle watering with tepid water is given, using a little weak liquid manure water as occasion may require. As they advance in growth they are secured to the upright rods until they reach the rafters, and are then trained over the pathway to rods fastened to the rafters and extending the whole length of the house, forming when in fruit a sight well worth seeing.

By the above mode of culture, and other means, I secure a supply of Cucumbers throughout the year without disease or those unsightly club-like fruit so often complained of. When other Cucumber plants come into bearing in spring, those grown for winter production are taken away and renewed in the autumn, as I prefer young plants, so that I have no experience to relate about stems as thick as walking-sticks, or lasting for years. I have practised this system for years, and it has answered the purpose intended; and I shall be happy if the facts stated prove of service even to one individual.—Veritas.

At this place I have charge of a small house, 11 feet long, 11 feet wide, and 8 feet high at the back. There is a bed or pit in front for Cucumbers, 11 feet long, 3 feet wide, and 3 feet 6 inches deep. The house is heated by six pipes—namely, a three-inch flow-and-return at the back, a two-inch flow-and-return in front, and in the pit, 6 inches from the bottom, four-inch flow-and-return pipes, respectively 6 inches clear of the front and back walls of the pit, with an interval of 15 inches between the pipes. Above the pipes there is an 18-inch chamber, six pillars, 6 inches square, being built from the bottom, and two wattled hurdles placed lengthwise upon the tops of the pillars. On the hurdles are laid a few rough branches or faggots opened out, and then some good rough soil of a light nature mixed with rotten dung and leaf mould. This house was put up two years ago last summer, and since then I have had very good fruit. From November, 1865, to the end of May, 1866, I cut some hundreds of Cucumbers. I then pulled up the plants, cleared out the old soil, and gave the house two good coats of whitewash, hot lime, and sulphur mixed together. Fresh loam, stiffer than for Cucumbers, was then put in, and some good strong Melon plants planted where Cucumbers had been. Plenty of fire heat was afforded, and attention was paid to syringing and applying manure water, and the result last summer was a crop of nineteen good fruit.

After the Melons are over the house should be again cleared out, and strong Cucumber plants planted by October to produce in winter and spring. After planting water rather sparingly, and as the plants become stronger give them a little weak manure water; but when they begin to bear increase the strength.

For the last two months I have given my plants about ten gallons of strong manure water, and on the 23rd of March I counted sixty fruit, from 3 to 15 inches long, whilst some of the leaves were 13 inches across.

I do not much approve of the tank system of Cucumber culture, especially for winter. It has failed at several gentlemen's places near Bath, after the plants were about 8 feet long. It appears not to afford facilities for enough of drainage, for the roots going down to the hard tank, owing to watering, become rotten, and the plants die. If I had charge of a Cucumber-house with a tank, I would place boards on bricks so as to form a chamber 6 inches, or, better, 1 foot high (or several faggots might be used instead of boards), and on this platform I would place soil for the plants.—G. L. Drummond, *Gardener, Highbridge Hill, near Bath.*

TRAINING VINES.

Will Mr. Thomson kindly explain in your Journal the position of the summer shoots on his Vines, with the rods or stems 2½ feet apart; also, how short they are pruned in the winter, as most of the Vines I have seen are from 40 to 42 inches apart? Secondly, What weight of Grapes from a rod 19 feet long, does he consider to be a good crop, in April, in June, and in August; or will the Vines at each season bear an equal weight?—G.

[In reply to "G.," let me say, that he will have observed that I advise that two rods should be grown from each Vine, "not closer together than 2½ feet." If he finds this too close he can give them a little more space. I grow them so in several houses, and wider apart in others; but writing principally to guide amateurs who have not much space to spare, I

gave the minimum, and I find no difficulty in growing Vines so. An amateur who lives close by me, who produces splendid crops of Grapes, and who took some of the leading prizes at the great show in Edinburgh in 1865, grows them even closer than 2½ feet. The position of the lateral shoots, starting as they do at an angle of 45° from the parent stem, is, that their points cross each other, but this causes no difficulty when one lateral only is allowed to grow from each eye, and the eyes are 12 inches apart on the average. I prune to the bud at the base of the lateral.

Of Grapes ripe in May, I would consider 40 lbs. a good crop for rods 19 feet long, and 3½ feet apart; if ripe in September, 50 lbs. If grown 2½ feet apart I would allow a deduction of 10 lbs. in each case.—Wm. Thomson, *Dalkeith Park.*]

ORIGIN OF TRICOLOR PELARGONIUMS.

In addition to the beauty of the foliage of Variegated Pelargoniums, there is an interest in their production as an aid to a solution of the mysteries of hybridisation and variegation, and however opposite the deductions of operators, a record of their experience will always have a high value.

Your latest correspondent on this subject is Mr. Pearson, and he adds to his useful remarks an apparent objection to the connection of scientific inquiry with the practice of cross-fertilisation for new forms and colours; that such an objection cannot be really intended must be obvious, for Mr. Pearson had just advanced good reasons for his selection of plants for fertilisation. In the same way the Mr. Smith, of Dulwich, that he names, does not deal haphazard with pollen and pistils. I know well Mr. Smith's careful combinations, his unwearied care, and the beauty of the result. It is an acknowledged truism that the more we know the better will be our practice. Investigation conducted in a scientific spirit cannot fail to give new truths that will admit of wider application than mere Pelargonium culture.

With reference to the Zonal Pelargonium leaf, Mr. Pearson remarks, "that from some unknown cause the dark colouring matter has turned red, and that this tendency becomes hereditary." Let us endeavour to make a step towards this "unknown" cause, it may be but a very short one, but it will be an advance.

Yellow, red, and blue, and their combinations in their infinite variety, give us the whole range of our experience of colour; and a leaf of the Zonal Pelargonium in its so-called green state contains within itself the three primary colours—yellow, red, and blue. For example, sketch the outline of the leaf, mark thereon the zone in red; then, with a transparent colour, cover the whole within the outline with yellow; the result is a yellow leaf with an orange zone. Again, cover the whole with blue, and, if the proportionate depths of tint have been duly observed, the appearance of a green leaf will be produced with a zone of dark ill-defined colour. The beauty of the Tricolor, whether white or golden, depends upon a disturbance of the proportion of the three primary colours. A partial removal of the blue gives the golden ground and the brilliant orange or red zone, and the partial absence of the three colours leaves a white ground. The specimens upon which changes are required should be treated for combinations as the pigments in the artist's colour-box, and but for the many yet imperfectly investigated causes, the certainty of tint in the cultivator's hands would be equal to the artist's; but with both much will have to be studied before a desired result can be produced—the influence of sex, the unknown tendencies to hereditary re-appearances and divergences, the singular production of new colours by sporting, as it is vaguely termed, instead of direct from the seedling stock, together with atmospheric and actinic influences, all tend to veil this subject with the mystery attendant upon uninvestigated causes; still a glimpse of light can be obtained, and by its guidance the production of a Tricolor or Variegated Pelargonium is not the mere chancework it is usual to consider it.

With a better knowledge of animal physiology the greyhound-breeder, alluded to by Mr. Pearson, would obtain better results, with fewer puppies and less hanging. When vegetable physiology becomes better elucidated, in the like manner the gardener will have less necessity for large seedings and fewer contributions to the rubbish-heap. My own experience has been that, with some attention to the laws of colour, I have with a very few seed-pans been able to follow very closely upon the largest Pelargonium growers.

Mr. Pearson observes that no single plant of this class was antecedent to Mrs. Pollock. I am sure he will pardon a correction of this statement. The first Golden Tricolor I saw was raised some fifteen or twenty years ago by Mr. Basket, of Blackheath, and appropriately named Rainbow. I cultivate it still, and largely, for its splendid truss, in the borders; in early spring, the crimson zone on its yellow ground has not yet been surpassed. As summer advances the green predominates. From Rainbow a sport was shortly after produced with a silver ground, a forerunner of Italia Unita; this plant still holds its place in the catalogues as Burning Bush. From these plants, long previous to Mrs. Pollock, seedlings of merit have been raised at Mr. Hally's Nursery, Blackheath. This Rainbow must not be confounded with a second and later plant of the same name, and altogether distinct from it.

I notice this as pure matter-of-fact, and without the slightest intention to detract from Mr. Grieve's claim, should he make it, to a different origin for his splendid seedlings. For the pleasure they have given me I am under a deep obligation; and I wish, for the light he could throw on this subject, that we knew more of the history of his unrivalled plants.—M., *Deptford.*

P.S.—Since writing the foregoing, I have had the great pleasure of reading Mr. Grieve's remarks in your last. They so perfectly take precedence of the little I can add to a knowledge of this subject, that I leave it to your discretion whether my notes should appear. If inserted, I wish to say also, that though it would be presumption on the part of a mere experimentalist to differ from a master upon a point of practice, yet upon a point of theory important to the question, Mr. Grieve will, I hope, receive the following correction in the spirit it is offered.

Mr. Grieve, states that "knowing, as I did, that the mingling of brown and yellow will produce red," he proceeded to experiment on this basis. Now red being a primary colour, it follows in theory that no combination can produce it, and any attempt in practice must fail; the after-reasoning is consequently unsound. The yellow margin under the brown zone would not produce red, as Mr. Grieve supposes. This can be proved by placing two transparent mediums of those colours over each other. In fact, the zone appears brown on account of the junction at that part of the three primary colours, as I have endeavoured to explain before, and wherever the blue is abstracted the yellow takes the place of the green, so to speak, and the brown becomes red, or rather orange red. In practice Mr. Grieve has admirably redeemed this little slip, by so ably selecting the means of abstracting the blue, and releasing the splendid combination of yellow and red, as exemplified in Lucy Grieve, &c.

A further removal of yellow developes the zone into carmine, but it is at the expense of endurance to the leaf; it rapidly loses its ground. The great point to combine beauty with vitality is to secure a rich orange ground, the best example of which that I know, is Golden Pheasant, the best bedding plant of this colour I have seen. It increases in size and beauty of colour by exposure in the open borders.

If correct in the foregoing, I deduce this, and offer it as a suggestion to growers—in changing a green leaf to variegation nothing is added, it is a matter of abstraction, more or less simply; and if this be true, it would certainly smooth the path to yet more brilliant combinations of leaf-colour than we now possess.—M.

LEGUMES FROM MADAGASCAR.

Some two months ago a vessel called the "*Wild Wave*," arrived from Madagascar, being the first ship from thence to this port, with an assorted cargo of the produce of the island. Besides sugar, coffee, rum, 18,000 mats, most beautifully made, and 2000 straw hats, as good as the best Leghorn, there were some bags of Beans, Peas, &c., the latter only sent as samples. I bought these by auction, and I have been giving them away amongst my horticultural friends. I send you a small sample of three kinds, marked 1, 2, and 3, and shall be glad if you can throw any light on their uses, if they can be used as a vegetable, their names if possible, how they should be planted, and on what sort of soil. I have about a bushel of each left. If you think them likely to do well in this country, I should be glad to send any person who would like to try them, a small package of each on receipt of thirteen stamps. The mats and hats were sold by auction at 6*d.* each.—George F. Martin, *Broad Green, near Liverpool.*

[The first commercial venture from Madagascar to Liverpool is highly interesting. The samples of seeds sent are

—No. 1, a Bean almost globular, and in size and colour resembling the largest, smooth, white garden Pea. No. 2, are seeds of a Phaseolus, and they resemble very closely those of a liver-coloured black-speckled Dwarf Kidney Bean. No. 3, are also, we think, seeds of a pygmy Dwarf Kidney Bean, or some genus nearly allied to Phaseolus. They are rather larger than Laburnum seeds, and dun-coloured. We recommend those of our readers who have hothouses or warm greenhouses to avail themselves of Mr. Martin's offer. The plants may prove as hardy as our Kidney Beans. We suspect that like similar legumes in India, the seeds are cultivated for the oil they produce.—Eds.]

SOIL AND TREATMENT FOR CAMELLIAS.

I have read the accounts of the various methods of cultivating the Camellia given since Mr. Pearson told us that the best soil to grow it in is fresh turfy loam pared off the surface of the field and used on the day it is cut; and I am very glad, although I was doubtful of it at the time, that such a simple method seems to grow the plant so successfully.

Camellias are indispensable for the decoration of the greenhouse and conservatory, and almost every owner of a glass structure likes to have a few of them; but we do not always find them in a thriving condition.

In the Journal of April 4th Mr. J. Harris says Camellias are semi-aquatics, and that he cannot obtain bloom if he uses loam in the soil. I will relate my experience with them, and detail the mode of treatment by which I have found them succeed best.

The first Camellias I had under my charge were grown in a small greenhouse of the half-span description and facing the west; a stage all round the house and a table in the centre completed the internal arrangement, and on the back stage the Camellias used to be placed during the growing season. The only soil that could be obtained was peat earth. The soil of the small heaps which the moles threw up as they burrowed underground was collected, brought home, and used at once; and in this the plants grew very satisfactorily, making beautiful dark green foliage, but producing only a moderate quantity of bloom.

My next experience was with plants grown in turfy loam not fresh cut, but they did not succeed so well in this as those previously noticed. The foliage was of a lighter green, and when the plants were turned out of the pots the roots had not the same healthy appearance. They made their growth in a lean-to vinery, and were not, I think, effectually shaded from the direct rays of the sun. Shading is of great importance in the cultivation of the Camellia. I always shade the plants after the 1st of April; those in the greenhouse are shaded to prolong the bloom, and those making their growth to prevent the leaves from being blistered or burned, and consequently rendered unsightly. The shading used is of the lightest description—No. 1 tiffany; it is to be obtained in pieces 20 yards long and 38 inches wide, at 7*s.* or 8*s.* per piece.

Part of the collection here has been moved to the second vinery, which has been lately started, where the plants have a temperature of 55° at night, and the remainder are also placed there as they finish blooming. They are syringed twice a-day, at 6 A.M. and at 3 P.M.; in bright sunshine they are dewed overhead two or three times in the course of the day; under this treatment they grow freely.

As soon as the buds are set the plants are taken to the potting-shed, and those that require potting are potted; the soil I now use for this purpose is two parts turfy peat and one part yellow loam, with some silver sand and broken charcoal mixed with it. I have used crushed bones, cow and other manure; but I never do so now, as I find the plants succeed better without the addition of manure. I never even water them with manure water.

I used to shift the smaller-sized plants every year; but I found such sorts as Henri Favre, Jubilee, Mathotiana, and some others, did not open their flower-buds. These being very hard at the time of opening, the inner petals in trying to expand burst and split the outer ones, and none of the flowers opened properly. This occurred in two successive seasons; but last summer I did not shift any of the varieties having this fault, and this season all the above have opened their flowers to perfection. If the drainage is all right Camellias will flower better in the second year after they are potted than they will in the first. I rarely find the drainage of my plants defective, as I never set them out of doors; consequently they are never at any time drenched with rain, and worms cannot find their way into the pots.

Camellias require more water while making their growth then they do at other times; but even then I am careful not to water them until they actually want it, and I may here state that over-dryness at the roots is quite as injurious as too much water.

Camellias, like other plants, require attention, and those who wish to grow them well must attend to them every month in the year; inattention to watering will cause the flower-buds to drop, and if the plants are not shaded from the direct rays of the sun the foliage will be rendered unsightly. I generally have to thin out two-thirds of the flower-buds. My plants were never better here than they have been this season, grown in the compost and treated as I have described.—J. Douglas.

ROSES AND OTHER FLORISTS' FLOWERS

AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW.

Anything more wretched, each in its way, than the Society's two Spring Show days this season it is well nigh impossible to imagine. More 's the pity, for more creditable exhibitions could not well be imagined for so dreary and gloomy a winter as it has been. Roses especially were wonderful, and in some of the collections the very *ne plus ultra* of growth. Take, for instance, those with which Mr. Turner gained the first prize for nine; they comprised Souvenir de la Malmaison, this was not up to the mark; Madame Falcot, a magnificent plant, with every bloom just in its perfection; Général Jacqueminot; Souvenir d'un Ami; Celine Forestier, the best pot specimen of this not-very-free-flowering Noisette that I have ever seen; Vicomte Vigier, good; Senateur Vaisse, very fine; Charles Lawson; and a splendid plant of Baron Adolphe de Rothschild. Mr. Wm. Paul had Victor Verdier, Madame Villermoz, Mrs. Wm. Paul, Jean Goujon, loose; Anna Alexieff, Madame de Stella, Celine Forestier, Gabriel de Peyronny, and John Hopper. Messrs. Paul & Son were third with Comtesse Cecile de Chabrillant, Lord Clyde, fine; Madame Wood, Alba Rosa, Charles Lawson, Souvenir d'un Ami, Madame Villermoz, Senateur Vaisse, and Anna Alexieff.

For new Roses of 1865 and 1866 Mr. Wm. Paul was first with Alfred Colomb, a fine flower; Alba Mutabilis, loose; President Mas, thin; Madame Rousset; Mademoiselle Marie Rody, a splendid Rose; Mademoiselle Berthe Levêque; Elizabeth Vigneron, rough; Fisher Holmes, bright but thin; Pline, thin; Comte Alphonse de Serenye, large, loose; and Mademoiselle Eugénie Appert. Mr. Charles Turner was second with Duchesse de Caylus, very fine; Elizabeth Vigneron; Charles Wood, fine; Mademoiselle Marguerite Dombrain, Marguerite de St. Amand, Madame Eugène Appert, Aurore Borćale, good; Alba Mutabilis, Maréchal Niel, very fine; Dr. Andry, very fine; Camille Bernardin, very fine; Exposition de Brie, very fine. Messrs. Paul and Son had Joséphine Beauharnais, very fine; Alfred Colomb, fine; Princess Mary of Cambridge, good; Pline, thin and rough; Mademoiselle Marguerite Dombrain; Jean Lambert, good; Charles Rouillard, Elizabeth Vigneron, Mademoiselle Berthe Levêque, Madame Fillion, good; Madame Moreau; Maréchal Niel, very fine.

For single specimens Mr. Wm. Paul was first with a nice plant of Madame Alfred de Rougemont; Mr. Turner second with François Lacharme. Of Amateurs Mr. James was the only exhibitor with small plants of Madame Falcot, Jules Margottin, John Hopper, Anna de Diesbach, Souvenir d'un Ami, and Victor Verdier.

Judging from the plants exhibited, the following are the best of last year's Roses:—Amongst dark-coloured flowers, Alfred Colomb, Exposition de Brie, and Madame Marie Rody; of rose-coloured varieties, Joséphine Beauharnais, and Mdlle. Marguerite Dombrain; and of yellows, Maréchal Niel. Messrs. Lane, of Berkhampstead, did an act of kindness to Rose-growers by exhibiting some plants of many of the new varieties. Grown as they were and forced hard, it is impossible almost to judge of the merits of Roses; but as all were subject to the same conditions one could just judge comparatively, and unquestionably my supposition that Antoine Ducher would prove to be one of the best Roses, if not the very best Rose of the year, is justified by the plants exhibited. It was by far the best—a large-petalled flower of great substance, and of a good fresh colour. Bouton d'Or and Madame Margottin amongst Teas promised well, and so did Gloire de Montplaisir, H.P., Madeleine Nonin,

and M. Plaisançon; but all who know what grafted plants of two or three months old are, will understand that much could not be predicated of them.

The season has been backward and unfavourable for Auriculas, and a poorer lot I have not seen staged for some time. Mr. Turner's were, as usual, the best, but he must have been hard up when he put Gorton's Stadtholder and Pillar of Beauty into his collection of twelve. Besides these two old and worthless flowers—worthless, that is, in the eyes of a connoisseur—he had Richard Headley, grey, fine; Lady Richardson, rough; Sims's Eliza, self; Ashton's Prince of Wales, Fletcher's Mary Anne, Lightbody's Meteor Flag, Lightbody's Fair Maid, Read's Miss Giddings, and Clegg's Crucifix. Amateurs were still more mediocre. Mr. James was first with Union, Anne Smith, True Briton, Ne Plus Ultra, Lycurgus, Lovely Anne, and Eliza. Mr. Butcher was second with Imperator, Mrs. Sturrock, General Neill, Conqueror of Europe, Countess of Wilton, Delight, Smith's Emancipator, and Black Prince. Of Alpines Mr. Turner had a good collection, chiefly his own seedlings—Brilliant, Defiance, Fire King, Ralph, Saturn, Topaz, Norah, Selina, Leo, Nero, Mabel, Edwin, Brutus, Sparkler; and Conspicua, Dazzle, Brutus, and Lord Lee, older varieties.

In Polyanthus Mr. Wiggins, gardener to E. Beck, Esq., of Isleworth, sent some very fine plants of Model, Unique, Dark Beauty, Elegans, Little Pet, and Butterfly, all fine, but, I am sorry to say, still unattractive to me. Mr. James, gardener to W. F. Watson, Esq., of Isleworth, had some fine Pansies in pots, also some excellent cut blooms. Those in pots were J. B. Downie and Miss Hill, yellow grounds; Princess of Wales and Cupid, white grounds; and Rev. H. H. Dombrain, Black Douglas, and Rev. J. Dix, dark selfs. Amongst his cut blooms were Masterpiece, Rev. H. H. Dombrain, General Lee, Concord, George Wilson, Norma, Attraction, Cupid, and Masterpiece.

Amongst seedling florists' flowers there was not much. Perkins's Queen Victoria Tricolor Pelargonium promises to be a valuable addition to this most fashionable and popular tribe. Lavinia Maggi rosea, a sport of that fine Camellia Lavinia Maggi, appeared to have lost in shape and substance by the sporting. A seedling Alpine Auricula called Emma was good in shape, not remarkable in colour; and Mr. Fairbairn's Cineraria Beatrice seemed to be a large and showy flower, and very free-flowering, although not very strong in habit, apparently. A golden-leaved variety of Pelargonium called Jason also promised well: it was exhibited by Mr. W. Paul.

Other florists' flowers there were, such as Azaleas and Amaryllids, but they have already been described; and I think it is hard now to say what is not a florists' flower, for the hybridiser is making inroads in all directions, and we shall have to give up a term which ceases to be definite.—D., *Deal.*

CAMELLIA CULTURE.

If I understand Mr. Pearson's letter which appeared in your last issue, he seeks to establish two propositions.

1. That *he* can grow Camellias.
2. That *I* cannot grow Camellias.

As to the first, I am glad to hear him say that he is so successful in his culture, no matter how he does it, although, according to my observations and experience, his practice is calculated to grow leaves rather than flowers. "Dark Laurel-like bushes amongst which you might have hidden a bullock" are not what I want, nor do I think they are exactly what the public in general want. Mr. Pearson is, apparently, not aware that his is the old way of doing these things, at least I practised it when a boy, and abandoned it when I began to inquire the why and wherefore of this and that practice. There are, however, often different and apparently diverging roads leading to the same goal, and I have no wish to depreciate the honest efforts of any fellow-labourer, however humble.

The second proposition I cannot, for business reasons, allow to pass unchallenged, lest it should be believed I send purchasers of Camellias to his nurseries instead of to mine. I have now some thousands of young Camellias grown according to my rules, of which I will not boast, but invite Mr. Pearson and the public generally to come and see them. Mr. Pearson will not, I hope, attribute it to any want of courtesy that I decline to embark upon the sea of controversy. The course I have marked out for myself, from which I must not be drawn aside, leaves me no leisure for such labour. Perhaps, too, the public may regard as a higher proof of the soundness of my rules than any mere assertions or assumptions of mine, the facts that the first prizes for twelve Camellias were awarded to me both at the Royal Botanic and the Royal Horticultural Societies' Exhibitions this year, which Exhibitions are open to the whole world.—William Paul, F.R.H.S., *Paul's Nurseries, Waltham Cross.*

THE BLUE PRIMROSE.

The blue Primrose certainly is a Primrose, but one in which the blue colouring matter, present in all red flowers, is by the strange chemistry of Nature either more than usually predominant, or is modified by the same power so as to simulate an alkaline reaction. Although this curious plant, like many other long-cultivated garden subjects, is barren as a bearer of seed, yet its pollen will fertilise other Primroses. The produce is a race of curiously-coloured plants, not so blue nearly as the parent, but giving true evidence of its origin in shape, habit, and marking. They also turn very blue after a frosty morning. Some other red Primroses, however, do the same, showing that the blue matter is only masked by another influence, and ready to appear under altered conditions.—R. T. Clarke, *Welton Place, near Daventry.*

JOTTINGS FROM CANADA.

I have read with much pleasure the various contributions on Potatoes and their culture, which have appeared in the columns of "our Journal" since the advent of the new year. Like "D., *Deal,*" Mr. Dobbie, Mr. D. Thomson, and others, we have found that medium-sized sets, planted whole, have produced the best return. In our climate, a very warm and dry one in summer, the system of planting on the flat is greatly to be preferred to the ridge system, as the ridges, particularly when with manure underlying them, are very apt to dry up.

In our markets no value is placed on the earliest varieties of Potatoes, such as the Ash-leaved Kidneys or the early round sorts, for unless size is attained the crop is unsaleable, quality for early kinds not being taken into consideration. We cannot, for fear of spring frosts, plant in the open ground until the beginning of May; but for all this can turn out very fair-sized tubers by the beginning of July. I imported eighteen varieties from England last spring. The tubers were very much shrivelled when they arrived, and had sprouted much, so that they were not in a fit state to give a first-rate return, and many kinds suffered sadly from disease in consequence of the protracted autumn rains. The best among the lot was Milky White, which yielded well, was first-rate in quality, and entirely exempt from disease. This will, I think, prove very valuable in Canada. Next came King of Potatoes, a good cropper, handsome in appearance, of fair size, and free from disease. Webb's Imperial and Gloucestershire Kidney produced a splendid crop, but rotted badly. Flour Ball, Dalmahoy, Forty-fold, Pink-eyed Regent, and Improved Early Shaw turned out well, but were considerably diseased. White Rock will be a useful sort for field culture, as it crops well and comes out sound; but is too deep in the eye to be handsome. Ash-leaved and Lapstone Kidneys, Golden Globe, and Myatt's Prolific were all too small; but I shall try them again, and, with better-conditioned sets, shall look for better results. For quality Lapstone Kidney and Milky White are at the head of the list.

We have an orchard of three thousand Pear trees on the Quince and about five hundred on the Pear stock, now three years planted, and well furnished with fruit spurs, consisting principally of Duchesse d'Angoulême, Louise Bonne of Jersey, Easter Beurré, Buffum, Nouveau Poitean, and Beurré Diel on the Quince, trained as pyramids; and Williams's Bon Chrêtien (or Bartlett, as it is called here), Flemish Beauty, Beurré Clairgean, Sheldon, and Seckle as standards on the Pear. Our experience has proved that the trees should be planted so that the junction of the stock and scion comes just to the surface of the ground. If the stock is exposed it soon becomes hardened, and the growth of the scion greatly exceeds it, producing a protuberance, and the tree falls into bad health. I have never yet seen roots thrown out by the Pear above its junction with the Quince, even when covered with soil, although it is quite possible such may occur. Our trees are all budded, and the soil is a stiff black loam overlying the clay. The pyramids on the Quince stock are planted 10 feet apart, standards at 15 feet apart.

We, too, have a vineyard, but very different from that at Garston. Our border is that prepared by Nature, our vinery

a ten-acre field, planted with the American hardy native Grapes, of the kinds called Concord and Delaware, the first a black and the latter a red sort. Our Concords, however, would meet with a poor sale in Covent Garden, on account of the intolerably "foxy" flavour which they possess. The Delaware is a trifle better, but neither of them would suit an English palate unless, as is the case here, a taste for them were acquired. In this neighbourhood there is a good demand for the fruit, and the Vines will produce yearly from two to four tons of Grapes to the acre. They are trained upon upright trellises, and planted 8 feet apart.

I shall also plant out in June about two thousand plants of the Orangefield Dwarf Prolific Tomato. From a small packet of seed obtained from Mr. Williams, of the Paradise Nurseries, we grew last season about twenty bushels of fruit, and being so favourably impressed with it we saved a quantity of seed, from which we are raising plants for this season. It is dwarf, early, very prolific, and of excellent quality, and we hope to ship some hundreds of bushels to Toronto and other markets, where the fruit is in great demand.

The reports of the fearfully cold weather experienced in England fairly make one shudder. Our long, dreary Canadian winters bring about a great dread of cold. The mercury has not sunk lower than 10° below zero with us this season; but it sometimes goes down to 30° below, but not often in this part of the country. The monthly average mean temperature of the winter months at Toronto for twenty-five years is as follows:—December, 26.20°; January, 23.61°; February, 22.99°; March, 29.86°. The high maximum temperature attained makes this appear warmer than it really is, as the maximum counteracts the minimum, which is very low. The extremes are very great, the mercury rising to 50° and falling to 10° below zero in a few hours. In the course of a day and night I have observed a difference of 80° in the temperature, rising from 20° below zero to 60°, causing a rapid thaw and great floods, and much discomfort to both animals and vegetables. In spite of all this we manage to keep poultry, although Spanish are soon deprived of their combs and wattles, and even the hardy Game suffer. Our little English Game Bantam cock had to succumb during a "cold spell," as the natives term it, to the great grief of the household, for, like "Wiltshire Rector," we have a weakness for Bantams. "Dick" was a noble little bird, full of pride and courage; but Jack Frost was too much for him. A native-born son of his now supplies the vacant place, but is not looked upon so favourably as the little Englishman.—W. T. Goldsmith, *St. Catharine's, Canada West.*

CONIFERÆ AT BASING PARK.

A few days ago I visited that charming place, Basing Park, Hants, the residence of W. Nicholson, Esq., M.P., who has a collection of Conifers, comprising nearly two hundred different species. Although many of them are new, and otherwise delicate-growing sorts, I was much astonished to find that not one of them, with the exception of the Wellingtonias, which looked a little bronzed, had experienced the slightest injury from the severity of the late winter; while among the ornamental flowering trees and shrubs which are distributed over the noble pleasure grounds, a fine specimen of Garrya elliptica was completely destroyed, besides many of the Roses. I was informed that the lowest temperature at Basing Park was 2°, or 30° below freezing, and that it occurred on the morning of the 30th of January; on the morning of the 4th of January, the temperature was 2° higher, or 28° below freezing—certainly enough to try the hardy qualities of most plants. Such a winter as the past has enabled us to distinguish many so-called hardy species from those which are really so, whether Conifers, or flowering trees and shrubs; even what may be termed the delicate-growing sorts of the former far excel most of the latter in hardiness.

While referring to the hardiness of Conifers, who, I ask, would like to be without a collection of these graceful and beautiful plants? I do not consider a gentleman's establishment, however small, complete without one. In my estimation a well-designed pinetum stocked with a good collection of coniferous plants, is not excelled by any other branch of landscape gardening.

The pinetum at Basing Park is very prettily laid out, and divided into sections, containing the different genera of Coniferæ, and being well filled the whole presents to the eye a miniature forest of Conifers. These are all planted on mounds of earth, with a flattened top to retain water. The benefit of planting the Pine and Fir tribe on such mounds is great, for the roots run near the surface, and unless the collar is elevated, a Conifer seldom thrives. They are planted in some rich soil, and for that reason do not require manure water, but occasionally a little fresh soil is put round the roots to keep them in good growing order.

Every other part of the establishment was in first-rate keeping, and reflected much credit on the ability of the industrious and intelligent head gardener, who, during the few years he has been at Basing Park, must have been very active in carrying out the various and extensive alterations for the improvement of the place.—G. N.

ROYAL HORTICULTURAL SOCIETY.

Dr. Masters. in his fourth lecture on Saturday last, took for his subject the Leaf and its modifications. After stating that leaves served the double purpose of the lungs and stomach in the animal economy, being at once the organs of respiration and digestion in the plant, he pointed out the distinctions between them and other parts of the plant, and then passed on to the consideration of their arrangement on the branches, which, he said, was a matter of more importance than their mere form. The various ways in which they are arranged on the stem and branches were then illustrated, and the object in all these cases, he stated, appeared to be the non-interference of the leaves with each other, so that, however crowded, no two should completely overlap each other, thus securing a due exposure of all to light and air. Sometimes the same end was attained by the lowest leaf in a spiral arrangement being the largest, so that the upper leaves do not altogether overlap it. The fact that leaves are often bent out of one another's way, as exemplified by the leaflets of the Rose, was then referred to as another instance of the manner in which the arrangement of parts is made subordinate to the perfect performance of the functions which leaves have to fulfil as organs of respiration, exhalation, and digestion. The different parts of the flower were then shown to be mere modifications of the stem and leaves—to be originally identical with these in form, structure, and mode of growth, and to be arranged on the same general principles; but however varied in appearance, the only two absolutely necessary were the stamen and pistil. Dr. Masters then announced that the parts of the flower would form the subject of his concluding lecture.

FLOWERS AND THEIR FITNESS.

We often find the value and beauty of flowers lessened and spoiled by the unfitness, with regard to times and circumstances, with which they are often thoughtlessly or ignorantly used.

Who has not seen at times strange flowers chosen for adverse seasons—some gay, laughing, flaunting Poppies put to the gravest, most solemn uses, or the sad ever-mourning Jasmine adorning the young heir's christening cake?

I know some will think this mere affectation of sentiment, and ignore altogether the indwelling spirit of flowers. Call them so much form, and substance, and colour, and scent, and nothing more, there is still a fitness or unfitness in the use of them. The Camellia, for instance—who can think of it without visions of festive mirth, of brilliant lights, of shadowy forms of beauty, of manly forms of strength, with the lines of care and of speculation and of deep thought smoothed away? The Camellia is surely the belle of all flowers during the long winter season, gracing our dinner parties, our balls, and concert-rooms; gleaming out in rosy crimson streaks from flaxen hair, or showing off its depths of spotless whiteness among the dark braids of brown or black. How it shines out in the dull gloomy weather, prized by those who possess it, envied by those who do not! yet who, with any depth of thought or kindly feeling, would ever take or send such to a sick friend—to one who in pain or weariness lay waiting for the soft summer months and the dear summer flowers?

That pure white Stephanotis with its dark green leaves, waxy petals, and delicate perfume, may live and bloom in the pastor's study in harmony with all surroundings—fit presence with holy thoughts and high aspirations—and perhaps by some gentle refining influence make stronger, more heart-reaching, the written words; or it may soothe the griefs which often in quiet lay heavy on the thoughtful spirit; but it is out of its fit place amid the noise, and talk, and jest, and laughter, and ringing of glasses in the clouded tainted atmosphere of the squire's smoke-room, though his guests be "lords and dukes, and parliament men of renown."

That large Dahlia, with its splendid blooms, perfect in form

and substance and adjustment of petals, and which seem in their solidity as they could never fade or fall away, is unfit for that nine-feet cottage garden. All through the summer months it thrusts down its thick roots into the soil, greedy as an Ash tree, and waves in triumph its long, blossomed arms to and fro, a very Samson in strength. And yet it stands alone; the Daisies that used to make a neat border on the side of the pathway have pined away for want of food, the Primroses with their soft green leaves are dried up; for the Dahlia can spare no moisture, but spreads out its large leaves far and wide, to gather up all it can of the summer shower or the refreshing dew. There is not enough left for even a weed to live upon. The Rose tree growing round the window never attempts to flower until it has reached the thatched roof. It is like that Upas tree, within whose deadly influence, fable tells us, nothing would grow—it is a beautiful giant in a desert country, from which even the pygmies have fled. The dwellers in that little cottage need no sun-blind, for the Dahlia stands outside their narrow-paned window all day long, keeping out sunshine and light, and casting long shadows on their evening meal. It is sadly unfit for its situation. And then, with what dignity it might have worn its honours in some princely domain! Looked at from a distance, and backed by dark evergreens and old trees, it would have shown off all its beauty—been indeed a splendid object. It somehow reminds one of the Yorkshire labourer going to see his dairymaid sweetheart, and who, wishing to make himself grand, chose a Pæony for his button-hole, thinking, doubtless, that size and weight were everything with flowers, as he thought they were with pigs and poultry.

Yes, those large-growing plants have no fitting place in a small garden, whether it be a cottage or villa garden; they gather to themselves more than is their own, and even then obtain not so much as they need. The proud Hollyhock, growing up like a tree, with its thick branches set all round with Rose-like flowers, growing on and blooming on until cut down by the frosts of winter, is, like its cousin the Dahlia, out of proportion in a narrow confined space, and need never be chosen for want of suitable plants of more than equal beauty.

Hyacinths and Jonquils, beautiful as they are, and largely as they are grown for the purpose, are yet not fitted in all cases for home decorations; they are well enough in halls, staircases, and windows—indeed, in any open airy place. When brought into the warm, enclosed atmosphere of a living-room they become to many physically unbearable, bringing on a high nervous excitement, and causing unrestrained tears to fall in showers; to the sick and the delicate they are overpowering beyond measure. Never are they so fine or so agreeable as when grown in a cool greenhouse, or out in the open air with the fresh young grass about them, and the spring breezes wafting their perfume to each passer-by.

Fashion, or long usage, has assigned the Orange blossom as the bride's peculiar flower; and if it were tried, perhaps, the rule of seeming fitness could not easily be broken through, for each maiden in her turn would hold forth eager longing hands for it on the eve of her wedding day, and, perhaps, think she was not safely and truly married if she wore it not. And yet it is not the fairest or the most bride-like of flowers. Our remote ancestors knew best why they fixed upon it—perhaps they had not a long list to choose from. It is not half so pleasing as the Almond, Pear, Apple, or Plum blossom; indeed, it has little beauty and less grace, for its stiff petals seem as though they were cut out of cardboard, and its stamens as if they had no purpose in the world but to fall away and make visible the embryo fruit. Point out the Orange blossom to any young lady with a cultivated taste for flowers, who does not know what it is like, never remembers to have seen it, and sure enough the exclamation will be, "Is that Orange blossom? Is that all? I wonder they should make such a fuss about it."

Then there are the Campanulas—real home flowers, well fitted for those gardens where the owners spend much of their time, where the master digs for himself, and smaller, softer fingers tie up the slender stems, and clip off the dying blooms, so that the little plants can never do what they are always trying to—form their seed-vessels; then they flower week after week, holding up such clear delicate cups to view, clear and delicate as Dresden china, and in which one would think the fairies delight to bathe when the rain is over. Yet these plants make no show in the large garden; rather the reverse, for they appear to be always in a going-away state; but they have great interest and beauty in a smaller one when carefully tended.

And, then, there is the Rose—fairest and sweetest of all flowers, whether it be the old Cabbage Rose, or the latest, newest, and best; which may be grown to a like perfection in the little cottage garden and in the rosery of acres; which is never out of place, never unfit, never unacceptable; which may adorn the shopkeeper's back parlour, or the merchant's palace; which the poorest little maiden and the royal princess may wear with equal good taste; which all may give and all accept, whatever their difference of rank, or fortune, or culture may be, and which is never more touching, or possessed with a deeper meaning, than when offered by the poor to the comparatively wealthy. Surely of all flowers it is the richest, the most beautiful, from its earliest stage of formation to the dropping down of the last petals. No wonder it is a favourite, for it adapts itself to changing circumstances, and offers its blooms and its perfume without stint or measure; and even in their dying state the flowers are said to possess a soothing, healing influence. In sheltered nooks, in hundreds of gardens, the pale pink Monthly Rose opens wide its blossoms almost before the snow has melted from the neighbouring hilltops; and when the winter sets in and the year is dying you find the bushes covered over with a multitude of buds, wanting only a little dry sunshine to make them burst out as if to adorn a very Indian summer.

I know of no other flower equally fitted for all times and circumstances. Some few there are even better suited for house plants, some which, when submitted to the influence of artificial light, brighten up or deepen their colour to a marvellous intensity, like the Primula; it seems to laugh again when placed in the full glow of a lamp. It is hard to believe it is the same little pink flower, so ready to droop beneath the sun's rays; but then the Primula will not grow out of doors in our cold, damp climate, and it is not very well adapted for a window plant. Its soft woolly leaves cannot be kept clean without injury. The constant syringing which keeps the Rose tree green, bright, and pleasant, would be death and destruction to the Primula.

And then there are some plants and flowers fitted only for their native place, the spot of their birth—whose very life appears to be made up of the chilly night winds as well as the hot sunshine. Bring in the wild Bluebell from the hillside, and how poor and miserable it becomes—how its beauty and freshness pale away before the glitter and strong lights of the drawing-room. Better far to leave it in its own wild home—on the breezy common, or the rough hilltop, or the edges of the corn fields, bending gracefully on its thread-like stalks, and bravely breasting the rain and storms of autumn. There it flourishes without help or care, a perpetual gladness. The wind sweeping over the bearded Barley waves to and fro its tiny bells, as if making gentle chimes; and the full-laden bees find in them cities of refuge to shelter in, until the dark clouds pass away and they can see their way home.—Maud.]

PEAR CULTURE.

(*Continued from page* 71.)

Fan-training.—A maiden tree should be headed or cut down to within 1 foot of the ground, and immediately above a bud, with two or more buds situated a little lower. This heading down should be performed in mild weather between the fall of the leaves and March, November being a good season. In spring one shoot is to be trained upright, and one to the right, and another to the left, to furnish side branches. All other shoots should be rubbed off closely. With the view of giving vigour to the side shoots, these should be trained at an angle of 45°.

In the autumn the upright and both the side shoots should be cut back to within a foot of the point from which the latter take their rise. Three shoots must be secured on the upright shoot or stem of the tree as in the preceding or first season, and they are to be trained in a similar manner; on each of the side branches two shoots are to be left, training them in at an angle of 45°. All other shoots are to be stopped at the third leaf, and to one afterwards throughout the season.

In the third season of pruning the leader should be headed back to 1 foot, and the two uppermost side branches or shoots must be cut back to 1 foot from the stem of the tree; but the lowest two are not to have their shoots shortened in this or the following season. In order to secure the disposition of the shoots at regular distances a semicircle should be drawn at 10 feet from the stem, taking the setting-on of the lowest two side branches as the centre; the distances between the shoots or branches are measured on the semicircular line,

the first at 1 foot from the ground, and allowing the same distance upwards between every line, and consequently branch. This will be easily understood on reference to *fig.* 7. The lowest of the first pair of side branches on both sides of the tree is to be trained horizontally, and the uppermost on the same main side branch is trained by a line stretched from the setting-on or origin of the shoot to that point on the semicircle next above the first branch, which is necessarily horizontal. The shoots, or laterals as they are termed, that were stopped, are at the winter pruning to be cut-in to within an inch of their base. The highest two side branches are to be trained, and the shoots (two each) which they produce, to those points on the semicircle proper to them. The same stopping of the laterals applies to this as to the preceding year.

In the fourth year the leading or upright shoot, and the highest two side branches are to be cut back to within 1 foot of their base, and the uppermost of the next lowest side-branch shoots is also to be cut back to 1 foot; but none of the other shoots must be cut, except the laterals, which are to be cut back to within an inch of their base. The heading back of the fourth side branch will give two shoots, and these are to be disposed as represented in *fig.* 7, which shows by the figures 1, 2, 3, 4, 5, 6, and 7 the several headings back of the upright and side shoots necessary for securing shoots to cover the wall. The figures correspond to years, the shoots being severally cut at the bar or line across them, and in the autumn of the year corresponding to the figure. The tree is represented as trained on a 12-feet wall. I have been led to this mode of fan-training from the fact that the ordinary directions for fan-training are vague, and in many cases limited to "training in a shoot so as to cover the wall regularly in every part." Now this advice may result in the wall being covered, but in a very imperfect manner, and many parts of the tree may be ill-furnished with shoots.

The mode shown in *fig.* 7 is systematical, and may be practised by the least initiated in garden matters. The chief objection which I have to fan-training, and I do not advocate it for the Pear, is that the upper parts of the branches grow more than the lower parts, and give a preponderance of wood, which, if it does not interfere with the productiveness of the tree, causes the fruit to be far too much shaded. To obviate this defect of fan-training, when the shoots or leaders of the branches reach the semicircle they are trained horizontally, as shown in *fig.* 8, and upon that part the finest fruit is produced.

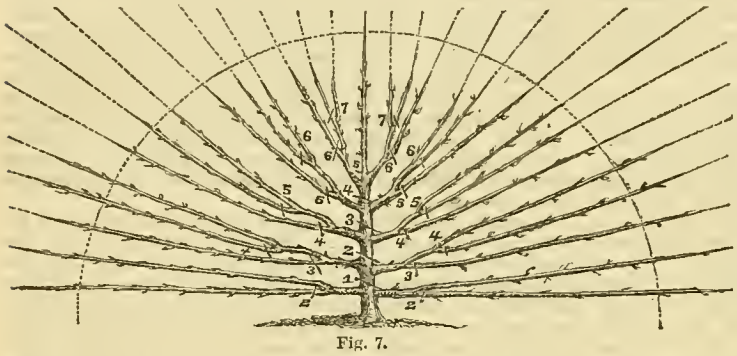


Fig. 7.

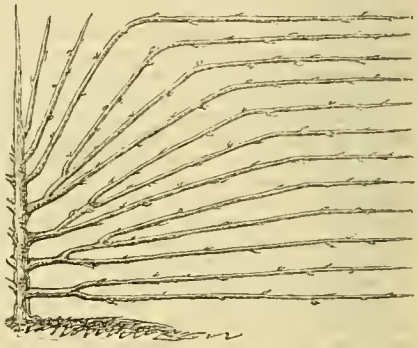

Fig. 8.

Upright-training.—The maiden tree should be headed to within a foot of the ground in the autumn. In spring the shoots from the uppermost buds should be examined, and the two most promising and situated nearest to each other should be selected for training, all others being rubbed off; then train those retained upright, but allowing a space of about 1 foot between them.

In the autumn of the first year's completion of growth the shoots, if each more than 3 feet long, as they will be, are to be depressed to a horizontal position, taking care not to break them, and let their points be turned up where the last upright shoots are wanted, and be cut off at two buds above the bend, as shown in *fig.* 9. When the buds break in spring the most promising nearest to the points at which the uprights are required, as well as one from each extremity, are to be retained, and these only, all others being rubbed off. Thus for furnishing six uprights three buds on each side of the stem should be left, the first 6 inches from the stem, and the next a foot from it, and so on, as shown in *fig.* 9, *a a*, *b b*, and *c c*. The result will be six shoots at 1 foot distance between each, as shown in *fig.* 10.

The uprights in subsequent seasons are not to be cut back at the winter pruning, but in summer, should one be disposed to outgrow the others, stop it when it has grown 13 inches, by doing which the sap will be diverted into the weaker shoots, and they will gain vigour. Shoots will result from the stop-

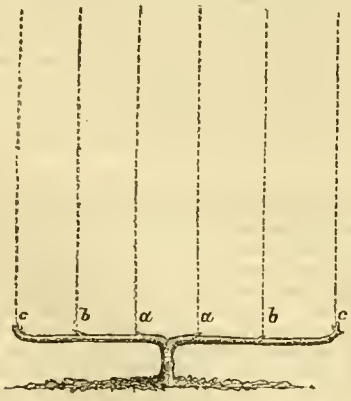

Fig. 9.

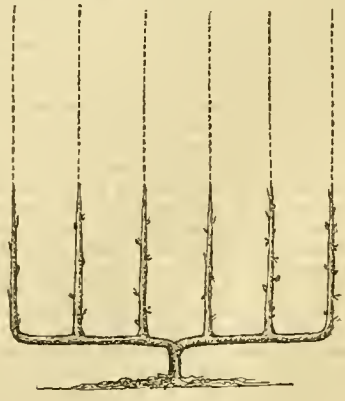

Fig. 10.

ping in the course of the same summer; the uppermost must be trained upright, and the others stopped at the third leaf. The laterals are to be stopped at the sixth leaf, and in autumn should be cut in to within an inch of their base.

If less than six upright branches are desired, the two shoots in the first autumn after their production may be cut back to 18 inches on each side of the stem for four uprights, two on each side of the stem. The distance between the uprights should be 1 foot.—G. Abbey.

(To be continued.)

NOTES AND GLEANINGS.

The subject of Tricolor Pelargoniums has lately occupied a considerable share of attention in our columns, and we are glad to find that the Royal Horticultural Society invite the raisers of these varieties to exhibit them at the Floral Committee Meeting on the 21st of May, communicating at the same time as much as may be known of their history and parentage. As an inducement, a silver medal is offered for the best collection, and it is hoped that the competition will not only prove of service by settling the comparative merit of varieties, but will also bring on a discussion, which may elicit interesting facts relative to their origin and the causes of their leaf-colouring.

—— We find that the "New Food," seed of which is offered by some seedsmen, and which Mr. Hullett surprised the world with through the pages of some of the daily papers under the name of Sorghum tartaricum, is the old Sorghum cernuum, a native of India, and much cultivated in Egypt and Algeria, but so tender that it ripens with difficulty in Italy, and not at all in France. The name of tartaricum was given to it by a seed house of Milan, for what purpose must be left to conjecture. It differs very much from the Sorghum saccharatum, the panicle of which is long, loose, spreading, and erect, while that of cernuum is short, dense, and capitate, and is always hanging downwards, or what botanists would call "nodding." Even for ornamental purposes it will never be of any service in England.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Amongst the numerous enemies with which the gardener has to contend, snails and slugs hold a most prominent position. The pressure of work in April and May is so great that the destruction of these depredators is apt to be neglected. Lime is well known to be destructive to them, but it is not always at hand in a quick state, and a shower of rain soon destroys its power. New sawdust and riddled cinder ashes, if applied in time, will likewise prevent their ravages. The ashes, riddled to the size of Radish seeds, all dust being excluded, and strewed over the young crop when just appearing above ground, I find efficient. An excellent chance is also thus afforded where occasion requires for a thorough mechanical division of guano as a top-dressing, so that the application will serve two purposes. A handful of good Peruvian guano, blended minutely with these ashes, would prove a ready mode of manuring a weak seed-bed. *Broccoli*, sow a portion of the late kinds. *Beet*, sow; also *Cardoons*, and the principal crops of *Salsafy* and *Scorzonera*. The seeds of the Beet should be steeped a day before sowing, especially if the soil is dry. *Celery*, prick-out about 4 inches apart, in an open situation, on beds formed of rotten dung and rich free loam laid on a hard surface. The growth of these plants should never suffer any check from drought. *Cucumbers*, prepare ridges for pickling sorts; these are best sown where they are intended to produce, and hand-lights, not now required for Cauliflowers, can be placed over the patches, although some even dispense with such protection. In case of accident, some, however, should be sown in pots, but not forced. *Camomile*, transplant. Sow a bed or two of *Herbs*, such as Pot Marjoram, Winter Savory, and Thyme, for next year's planting; this should be done every second year in all gardens, as the old plants are liable to wear out. *Parsley*, secure plenty in highly manured beds at the nearest end of the kitchen garden. Examine and remove the herb plantations. *Peas*, sow successions, also of *Broad Beans*, and amongst the former Knight's Tall Marrow should form a principal part; also plant-out *Kidney Beans* forwarded in pots or boxes, and sow for succession. *Rhubarb*, break off the flower-stems as they appear, unless a few be required to run up for seed. Thin plants in seed-beds, for if crowded in a young state their future success is endangered.

FRUIT GARDEN.

The operation of disbudding Peach and Nectarine trees should be proceeded with, more or less, according to the development of vegetation, and this will now be rapid. Owing to the advanced period of the season constant attention will be necessary in order that the removal of shoots may be gradual. Should the green fly appear, moisten the trees, and then dust them over with snuff or powdered tobacco leaves. Strawberry plantations will require abundance of water if dry weather sets in, and a piece of ground should be prepared for the reception of plants as they are turned out from the forcing-house. Thin suckers of Raspberries, leaving four or five to each stool.

FLOWER GARDEN.

Continue to fork up borders slightly that were dug in the autumn, and to regulate any of the more advanced herbaceous plants, tying them up if they require it. Clematises, or such climbers, must be frequently looked over, and nailed or tied as they advance in growth, at the same time removing abortive wood if not wanted for another season. Hardy annuals coming up too thickly should be thinned out and transplanted if required. Sow annuals amongst rockwork, and plant out any rock plants which have been kept in pots during the winter. Plant out in borders Ferraria roots that have not been potted, and plant also in beds Gladiolus cardinalis, Ixias, Tritonia fenestrata, &c., sticking Laurel branches thickly amongst them, as a sort of protection, for a few days; if frosts should occur a few mats might be thrown over them. Auriculas are now blooming; the amateur may experiment in cross-fertilisation to obtain new varieties. In growing for exhibition the pips which are mis-shapen should be removed with sharp-pointed scissors, and care must be taken that the trusses of bloom are not exposed to the too powerful action of the sun. If the seed gathered last season has not been previously sown the present will be a good time for doing so. Sow in shallow pans or boxes in light vegetable soil; it is only requisite to press the seeds on the surface and cover lightly with fresh moss. They will, when placed in a cold frame, be up in a few days. Put the sticks to Carnations and Picotees as soon as possible; if delayed the roots will be injured by their insertion.

GREENHOUSE AND CONSERVATORY.

See that climbers and all plants of rambling habit have due attention in regard to stopping, water, &c. Camellias forced into wood should have a trifling check as soon as the young leaves have attained their full size; this is best accomplished by diminishing the supply of water at the root. Continue, however, to shade, and syringe morning and evening. As the mixed greenhouse is everybody's structure, many plants will be treated under this head which should more properly be ranged under the heads Stove or Common Greenhouse. In doing this it will be presumed that the house is kept somewhat warmer than a cool greenhouse, or one in which artificial heat is used only to exclude frost. By keeping one end of the house (the end where the hot-water pipes or smoke-flue enters), closer, and using more atmospheric moisture and a greater amount of air at the other end, the amateur may, with such a house, indulge in many of the luxuries of larger establishments. Repot and propagate Begonias. This is one of the most useful families of plants that can be grown. Keep up a cleanly style of cultivation by means of sweet soils and improved modes of potting, together with the most complete drainage. Make frequent use of weak and clear liquid manure during the growing season.

STOVE.

The increased temperature will render great vigilance necessary to keep down the scale and bug on all kinds of exotics in warm atmospheres. Nothing can be more unsightly, or betray greater negligence, than plants swarming with these insects in otherwise finely-kept stoves. The foliage which plants are now making is, in many instances, destined to be their chief ornament for months, and if this is destroyed in this early stage the plants will exhibit all the evidences of careless management. See that the growing Orchids have due attention in regard to shading and atmospheric moisture, the latter is still lamentably deficient in many structures, or, if of sufficient amount, of too fluctuating and capricious a character.

PITS AND FRAMES.

Such plants as are removed to cold pits should be left uncovered during mild nights, and air should be left on pits and frames when the plants are sufficiently strong for turning out. Recently-struck cuttings of Verbenas might be pricked into rich beds, protecting them with hoops and mats, in a month they would be fine plants for removing into the flower garden, taking care to preserve balls of earth to the roots. Calceolarias, Salvias, &c., might be treated in the same way. Pot off tender annuals, and keep them in a mild heat until they are well rooted. If the plants or cuttings are not quite clean before removing them to the pits or frames, give them a good fumigation before they are taken out. See that there is a sufficient stock of everything to plant the beds properly; if not,

put in some more cuttings without delay; the plants which they make do admirably to fill up gaps in the summer.—W. Keane.

DOINGS OF THE LAST WEEK.

Since writing last we have had the gales, hail, and sleet of February, and the bright sun and warm genial showers of June in this changeable April. The pastures and corn-fields seem brighter and greener every day; in the garden Peas and Beans are healthy and strong; the old stumps of Borecoles and Brussels Sprouts are breaking afresh; Sprouting Broccoli affords frequent cuttings, and the white kinds are coming in to help us on before the Cauliflowers are ready. Even *Parsley*, which out of doors was almost out of sight, is now making itself visible. We hardly know where we would have been for a supply, always twice and frequently three times a-day, during this long winter but for a row in the cold orchard-house, and even that became almost invisible, though supplied with warm water, and litter was placed along the sides of the row to keep the heat in and the cold out. Without such advantages, Parsley must have been scarce in many districts where it was not boxed in houses or planted in frames. In fact, we have heard of some districts where for miles a bit of Parsley could not be had. We once walked through a kitchen garden of six acres, and for six months a leaf of Parsley had not been seen. Other crops come and go in their season, and if at all short the season goes on and the trouble is over; but Parsley is an every-day requirement, and often for garnishing is wanted several times a-day. In late ground, this month is the best time for sowing Curled Parsley for general use, and the plain Hamburgh for the sake of its roots. In a rather long practice we have been asked for Parsley roots three times, and in two of these cases we took up the roots of the common best Curled, as we gave up growing what was so seldom asked for. A change of guests and a change of managers in the kitchen will often render great changes in the nature of the supplies necessary, and the gardener must act accordingly: therefore it is well to keep many plants in the background, though they may be very seldom asked for. We generally sow a little Parsley about the end of June for successional supply, and especially if it is to be protected a little, as in the front of an orchard-house, in winter.

Though in general so easily grown, yet there are things about the thriving of Parsley that are beyond our ken quite as much as the disease in Cucumbers. We have ourselves been unable, and we have known cases of the first gardeners in the country being unable, to obtain a crop of Parsley in the ground on which it was sown. Though coming up well enough, it would become yellow and sickly, and dwindle away out of sight. Change of ground is always of importance; but the changing and pulverising of ground, and its exposure to air, were attended in such cases with no beneficial effects. The plants that came up so well would ere long take their departure. Now the remedy in such unfavourable circumstances—the only one we have ever found successful—is raising the plants in the open ground, or in boxes, and then transplanting in rows, instead of sowing where the plants are to remain. In some soils, where it is next to impossible to secure a good healthy plantation of Parsley from sowing and allowing the seedlings to remain where sown, with any due amount of thinning, in the same ground the Parsley will thrive if young seedlings are transplanted; the ground, of course, being in good order and the planting being done nearly as carefully as planting Onions—that is, inserting the root, and not burying the collar of the plant. As to the reason why Parsley will thus thrive transplanted, and not thrive where sown, we have none to offer; and though we have not experienced the difficulty referred to for many years, still the fact may be useful to those who are astonished to see their young Parsley plants disappear in an unaccountable way.

Herbs.—The winter having injured and thinned these, we have been engaged in making fresh beds and patching up old ones. It is late enough, but it will yet do to put in slips of Sage, which cannot be done without; Hyssop, Rosemary, Lavender, Savory, Thyme, though to make sure of the latter it is always safest to sow a little in a pot every year, and then transplant. Young plants will stand a severe winter, when older plants will be killed or have their stems split. Plants of Wormwood, Horehound, &c., may also be divided, or slips of them and Rue inserted; and if the soil is heavy, as ours is, and on a north border, some road drift, or very sandy soil, should be put about the slips and plants. Balm, much relished by many, is best divided, and comes best when this operation is done often and the ground changed. Tarragon, so much used by some in salads, succeeds best divided, or, if scarce of it, as we generally are, the young shoots when 3 inches in length strike freely under a hand-light, and may then be planted out in rich lightish soil, and sufficiently elevated not to suffer from damp. Fennel generally looks after itself, and, until this winter, we have seldom known it to be injured, even by hares and rabbits. A month ago we could scarcely have obtained a leaf out of doors, the hearts of the plants were eaten down as far as they could be reached. Where much is wanted in winter for fish, it is advisable to have a few pots under protection. In the position of our border we find, that to be sure, we also require to make at least one fresh bed of Mint in the year, and the best time to do that is when the young shoots are 2 or 3 inches high, as they generally have a few small roots at the bottom below the soil. These shoots make better beds than the running underground stems. Did we want much Peppermint we would use it the same way, and in stiff ground elevate the beds and dress them moderately with rotten manure. We have had to use Peppermint instead of Spearmint for lamb and Peas several times, and nothing was said about the difference; but no doubt Spearmint is better, and much of it is wanted from this time to the end of the Pea season. Peppermint is valuable for its essential oil, and the Peppermint water, the result of distillation.

Sowed in the same border Carraway, Chervil, Parsley, &c. It is always advisable to have a little piece of almost everything wanted in the herb way in such a place, and that place should be, if possible, as near as may be to the kitchen. We have in kitchen-serving days often had to walk nearly half a mile to the kitchen, and as much back again, with a sprig of Thyme, Basil, or Marjoram. If near the mansion such journeys and waste of time would be much lessened. When very near, the advantage is apt to be presumed upon. It very often takes much less time to serve the kitchen when the garden is a good way off from the mansion, for then everything, even to a bit of herb, must be ordered at once to prevent unnecessary waste of labour. Basil, Sweet Marjoram, &c., except in warm southerly places, require to be sown under glass and then to be planted on a south border. When these are wanted green in winter they must be sown in July, potted off, and kept in a moderate hothouse all the winter. Winter Marjoram, Savory, &c., may be divided or increased by slips.

Keeping Dried Herbs.—With us gardeners in general, nothing is worse done. We cut them just before the bloom opens, hang them up, and let them look after themselves; or, if we dry them well, for want of time and conveniences, they are put away where they are exposed to air, dust, and every possible evil. To have good dried herbs, from Parsley to Mint, unless there are the suitable conveniences, all such drying should come under the control of the housekeeper, or the head of the kitchen. The best place to dry them in is a hot room or closet, where they receive no sun, and then when dried, they should be kept in close bottles, or, which we prefer, not too much dried, then pressed with a press and heavy weights into thin cakes, to be wrapped in paper, kept in a dry place, and but little exposed to air. Many of our home sweet herbs thus treated would be no bad rivals to the much-relished Tea leaves of China.

Winter Greens.—Took the opportunity of a dry morning, when the ground could be trodden and raked, to sow the main supply of Borecoles, Brussels Sprouts, Savoys, and Broccoli; beat the seeds in with the back of a spade gently, and then covered with some sandy soil, and netted all over. We have been trying an old plan for keeping birds away—that is, making the seeds red with red lead before sowing, and as yet we see nothing touched. We did not use this plan, being afraid that some favoured birds might be injured, but if birds do not touch such seeds at all, there can be no injury to them; and as yet we do not see one meddled with. If either the seed or the powdered red lead has been kept a short time in a damp place, a very little lead will powder or crust the seeds. Even netting costs time and labour, and in most gardens the saving of work instead of making it must be the rule.

Globe Artichokes.—Ours, with less protection than usual, have stood the winter well, thanks to the snow, or we would have given more. This is a good time to make a fresh plantation, and where they are prized as early and as late as possible, the taking strong side pieces from the stools, and planting them in well-stirred, well-manured ground, in rows 3 feet apart and 2 feet in the row, will afford produce late in

autumn when the older plantations will be about over. These are kept longer in free bearing by having rich mulchings and manure waterings in summer.

Sea-kale.—We have gathered freely from under the common garden pots, placed over the crowns out of doors. We lately stated that as these pots were to have no covering, a quantity of rough hay and dry straw litter was placed round the sides of the pot inside, leaving a hollow in the centre. Without such precaution pots exposed are often injurious to plants inside of them in sudden and severe spring frosts. We have before now had Sea-kale not only retarded, but injured when thus covered, when it did not suffer in the least when fully exposed. In the last sharp frost Endive plants covered over with pots for blanching and fully exposed were much injured, whilst the plants that had nothing on them did not materially suffer. Thus, owing to the porousness of pots, and the free radiation of heat from them, we have uniformly advised that the pots containing even hardy plants should be protected in winter and spring.

Though we have a good piece of Sea-kale, we have taken up for forcing more than half of the plants available for cutting, and of what is left we would like to confine the one-half to spring cutting out of doors, and leave the other half uncut, so as to be taken up first next winter, as from not being cut the buds will be all the sooner matured. The ground cleared has been fresh dunged, ridged, and sandy soil and burnt clay added, and will be planted again, though not in accordance with rotation of cropping, with young plants sown about this time last year and now showing themselves. The old forced plants will also be replanted, but a few of them will be the worse for wear. For this lifting and forcing plan we find no system better than planting in rows 2 feet apart, and from 6 to 8 inches asunder in the row. This gives plenty of room for forming strong plants and prominent large buds or crowns. We may here advert to a statement of "Unsuccessful" who says he can only have his Sea-kale without forcing by covering in the open air, and he never can obtain it white and tender enough to please himself or his friends. We think he must err in covering with his pots, boxes, or whatever he uses, too late. If the plants shoot 2 or 3 inches, and have their purple colour at the points before covering them up, they take a long time to become well blanched; in fact, they will often be too long and leggy before the points lose their purple colour. The remedy is to cover as soon as the plants peep through the soil. When covering with pots or wooden boxes out of doors is resorted to, it is best to plant out in threes instead of in rows. When the plants are to be forced where grown and without pots, then the best plan is to place a mound of ashes over the crowns, a few twigs round, and cover with tree leaves, &c.

"Inquirer" wants to know "if he cannot have Sea-kale in April and May, without pots of any kind, as they are always being broken in moving, cracked with frost," &c. Undoubtedly he may, and by many modes. We just now cannot lay our hands on so many pots as we would like, and wishing also to be independent of litter for out-door gathering, we shall, if we can find time, adopt the following plan:—We shall line-off some small beds, 3 feet wide, with two-feet trenches between them, take out the trenches some 15 inches deep, and lay the earth on the beds, keeping up the sides with some rough slabs and posts. On these beds we would plant two rows of good plants 6 inches apart in the row, and attend to them during the summer. When convenient we would fill the trenches with sifted coal ashes, and then, in the end of autumn, clear the beds of decaying foliage, &c., and cover them over with fully a foot of the ashes. Then in April and onwards when we saw little mounds appearing on the ashes, we could examine and cut the Sea-kale. When "Inquirer" had gathered all he wished, he should put back the ashes into the trench for a future occasion, and dress, manure, and attend to the plants in summer. If he filled the trenches with hot fermenting matter in the middle or end of March, he would gather all the earlier. Could we easily obtain bog or peat earth fine, we would prefer that much to ashes. We have never seen whiter and sweeter Sea-kale than that which was blanched by a covering of bog earth, and the same earth had lasted many years, being placed in a heap when the crop was gathered. We would here add, Have nothing to do with sawdust, whether fresh or otherwise, for this blanching purpose. It is almost sure to flavour the crop.

Cucumbers bearing only too freely from having a little very old cowdung in the compost, showed in that compost some signs of spawn running, and therefore gave a good watering with clear lime water of the right temperature. The stacked soil we use for general purposes has to be examined as carefully for spawn as for wireworms.

FRUIT GARDEN.

Planted out strong plants of Melons in a frame and heated pit. Could not find room for them earlier, but now will be able to harden and expose many subjects needing protection and heat previously. The chief work in this department has been watering under glass, and using drainings from the farm-yard when such could be procured. When that is not to be had, we use manure water from barrels, made with cowdung, soot, &c., clearing with a little lime. These barrels were old and rotten, full of holes, and of no use above ground except as firewood, but the worst holes patched, and the barrels then sunk in the ground to the rim, and banked firmly round with clay and tar at the sides, they have done good service for years, and may do for the same purpose for years more. Strawberries have the water varied. Plants, like men, prefer change of food.

ORNAMENTAL DEPARTMENT.

The out-door work has been much the same as in previous weeks, rolling, switching, and preparing for mowing, which ought to have been done, but we think we must roll again. We also turned over ground, planted Gladiolus, and took off cuttings of Hollyhocks. In-doors much potting has been done; bedding plants were moved, cuttings made, and temporary beds made for forwarding tender plants, besides pricking these out, hardening off, &c. We find that we can only allude particularly to two subjects.

1, *Making Slight Hotbeds.*—When we have nothing but the long litter from the stables and a very small quantity of droppings to so much straw, we like in general to throw such material together, well watered, for a week or ten days, and then use it for a bed, with 3 inches or so of tree leaves on the surface; but to save labour we often dispense with all preparation whatever, bring the littery dung from the stables, mix the droppings regularly through it, tread it regularly, which is like going into a fresh haystack, and then dash some water all over it, for there would be little or no heat without. The treading and the watering will bring a bed of such loose material seemingly 18 inches high down to less than 1 foot. We then add about 3 inches of leaves or half-rotten dung, tread firm, put on a surfacing of dry coal ashes, and there is a place for setting anything on in pots that requires a nice heat. Of course, if pricking out is the matter in hand, some light well-aired soil is used instead of the ashes. A little practice in the making of such a bed will insure a lasting mild heat, and the covering referred to guards against everything in the way of deleterious steam. This is a good plan for many purposes, when you cannot afford to work and decompose your little dung much before using it. Bulk, if not of the best, must often be made the most of.

2, *Watering* small seeds and seedlings sown thickly in pots and pans. We have often entered into details as to preparing seed pots and sowing; and now the seedlings are up as thick as grass, and there is no chance of pricking out as yet, for that takes up so much more room. Well, they must be watered, thick as they are, and "Anxious" says he watered carefully with a fine rose overhead, and next day a vast number of his plants—nay, whole pots were fogged off—gone just at the surface soil. How? Well, we cannot exactly tell why; we only believe the fact, and will merely mention the preventives. First, never water such tender seedlings overhead when very close together, but take a small pot with a spout, and from that pour water on a potsherd or oyster-shell at the side of the pot, so as to sail or flood the little plants with water without pouring it over them. Secondly, as soon as convenient take up the little young plants, not separately, but in patches, and prick out into other pots. You can thin afterwards when larger. In either case there will be but little dying off.—R. F.

TRADE CATALOGUE RECEIVED.

Ambroise Verschaffelt, 50, Rue du Chanme, Ghent, Belgium. —*Prix-Courant pour le Printemps et Eté*, 1867.

COVENT GARDEN MARKET.—April 24.

The supplies are heavy and the markets very dull, quantities of goods remaining on hand. Continental supplies are also in excess of the demand. Dessert Pears are now over, and but few Apples of good

quality are to be had. Hothouse Grapes and Strawberries are coming in in large quantities for the season. The best Potatoes are 10s. per ton dearer.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

Books (*Cobham*).—There is no such book at present. We shall publish one next year. (*A Constant Reader*).—We have a book full of plans now printing.

Seedlings (*F. H.*).—The Coleus seedlings are rich in colour, but cannot be judged of from a single leaf any more than can a seedling Verbena or a seedling Pelargonium from a single pip.

Soda for Manure (*Martyn*).—Your discoloured washing soda may be applied to the ground intended to be planted with Potatoes, or sprinkled between the rows of Cabbages, between Sea-kale plants, or on Asparagus-beds. One pound to 30 square yards will be sufficient.

Drunkenness.—"My gardener, I begin to fear, is a 'neer-do-weel.' He has a wife and three fine children, and is a most trustworthy, strong, active, clever young man, who thoroughly understands his business, and whom every one in the village respects when he is himself; but he is easily led away by his own 'chums.' I am never sure of him, and he frequently gets thoroughly drunk. I have a good garden, about 40 yards long by 20, with a most excellent modern greenhouse, and was seriously thinking of engaging him for my permanent and first gardener; but this is only his second week, and he has been off two clear days already. Would you recommend me to try him again?—J. P."

[It is too serious a responsibility for us to accept, and we cannot say Discard him, for if you do, and give his true character, no one will engage him; but we have small hope that you will be able to keep him. If a man, who knows that drunkenness ends invariably in ruined health, impoverished family, and the contempt of every one whose good opinion is desirable—if a man, notwithstanding, runs even the risk of drunkenness, it is such a proof of self-indulgence being preferred to all other considerations, that we never expect him to stop until he dies of delirium tremens and his family are beggared.—Eds.]

Town Flower Garden Planting (*Constant Reader, Cork*).—We have no doubt that the plan you propose will answer very well; and we hardly know how to advise you as to improving it unless we knew which part you wished to continue longest in bloom. The main part, which consists of two semicircular beds, making an oval, with the space between, and four beds round the oval, with straight lines on the outside, we would recommend to be planted with those plants that will stand for the season, instead of, as now, being partly filled with Calceolarias; and other beds with mixed Candytufts, which will only be a few weeks at their best. Thus, suppose you planted your two pointed semicircles (but which, by filling up the middle pathway, we would change into an oval), with bright scarlet Pelargoniums in the centre, yellow Calceolarias round, and a band of blue Lobelia outside; then of your other four clumps we would pair them on the cross, say two beds of Cerise Unique with Heliotrope for an edging, and two beds of Bijou Pelargonium with variegated Alyssum for an edging; or the Verbenas you have, if you like them better, might be round Bijou, with a string of Cerastium next the pathway. The five beds then would stand the season; and you might edge all your little square beds at the sides with the different Cerastiums, and in them plant the Candytufts, Astera, Saponarias, &c.; and if a bed went off, you could either replenish it, or, if a little seedy, it would not mar the general effect, which your mixed Candytufts, Asters, &c., dying off in the six central clumps would certainly do.

Planting Vine Borders (*G. I. B.*).—The chief injury done to Vine borders by planting them with flowers is, that the sun has little or no direct access to the border. We always advise not to plant them; but many in this respect go against their convictions. A skirting of Mignonette, &c., in front does little harm.

Pear Leaves Eaten by Caterpillars (*W. F.*).—Dust the leaves thoroughly with white hellebore powder.

Treatment of Czar Violet after Flowering (*J. H. H.*).—Presuming it to be in a pot in a cool house or frame, remove the plant after flowering to a shady border, and plant it out in a compost of rich turfy loam with a little leaf mould. If the plant is large and capable of increase, the runners may be slipped off, placed in small pots filled with a compost of sandy loam and a little mould, and set in a cold frame. Keep the plants rather close and shaded until they are established, then remove them to a shady but open situation, and plunge the pots to the rims. When the pots are full of roots shift into larger pots—say 4½ inches in diameter, using the same compost as before, and in July shift into six-inch pots, using a compost of turfy loam two-thirds, and one-third leaf mould, with a free admixture of sharp sand. The plants should be well watered overhead and at the root, especially during dry weather, and this treatment should be continued throughout the summer, avoiding anything approaching to a saturated or sour soil, of which they are very impatient. They may remain out of doors, the pots being plunged to the rim in coal ashes in a sheltered situation, or, better, in a cold pit or frame, protection being afforded from severe frost. You may turn out the plants as already mentioned in a sheltered, shady situation, previously dividing them and planting the divisions 6 inches apart every way, and keeping them shaded until established. They ought to be kept moist and be frequently watered overhead. Towards the end of September you may take the plants up with balls of earth, and place them in well-drained six-inch pots, or any size large enough to hold them well. Place them in a frame, and remove them as required to an airy shelf in the greenhouse.

Riddell's Slow-combustion Boiler (*Idem*).—It is efficient, and as economical as any boiler of its kind.

Cinerarias Flagging (*E. Y.*).—We think the flagging of the plants is caused by the compost being much too rich, and the roots being injured, the plants would flag under bright sun. We would advise your employing in future a compost of turfy loam from rotten turves two-thirds, and one-third leaf mould, adding one-sixth sharp sand, but no manure. We think if you use this rough, provide good drainage, and afford a light and airy situation, you will be more successful in future.

Vinery Aspect (*J. H. H.*).—The south side of your wall will do very well for a vinery, and the same aspect will answer for oblique cordon-trained Peaches under glass. The other side will do for Pears, but not for a vinery or Peach wall. The hardier kinds of Pears only should be planted against it. It would also do admirably for Morello Cherries. The south-east side would also grow Plums and Cherries.

Hardy Basket Plants (*Isa*).—There are few plants that are hardy in hanging baskets; they should have protection in winter, as their roots perish on exposure to severe frost. Polygonum complexum, P. vaccinifolium, Antirrhinum linariæfolium, Saxifraga japonica, S. sarmentosa, Sedum Sieboldi and its variegated form; Linaria cymbalaria, its variety alba, and the variegated form; Lysimachia nummularia, Lotus corniculatus flore pleno, Campanula garganica, C. Barlerii, C. muralis, Convolvulus mauritanicus, C. tenuissimus, Mikania scandens, Disandra prostrata, variegated Vinca elegantissima, and the gold and silver variegated-leaved Ivies.

Evergreen Oak Injured by Frost (*R. Capper*).—All you can do is to cut off the head of the tree immediately above the living part, and train any well-situated shoot as leader.

Correa Potting (*W. A. O.*).—Now is a good time to pot it, draining the pot well, and using a compost of two-thirds turfy sandy peat, and one-third sandy loam, with a free admixture of silver sand. It is well not to give large shifts; a pot 1½ to 2 inches larger than that in which it is potted is sufficiently large.

Daphne indica Potting (*Idem*).—The present is a good time to repot this plant, but it flowers more freely when the roots are confined.

Fertilising Aucuba Flowers (*Idem*).—If a flowering plant of the variegated kind were placed beside a male plant it would in all probability have the flowers impregnated; but, to make sure, the pollen of the male should be applied with a camel-hair pencil to the stigma of the female. The pollen will keep a long time—if kept dry for many weeks, but we do not think it will continue good until the following year. The flowers should be fully open when the pollen is applied.

Lapageria rosea Propagation (*Idem*).—It is raised from seed and propagated by suckers, layers, and cuttings of the half-ripened wood.

Bougainvillæa glabra (*A Subscriber*).—The Bougainvillæa is not easily flowered in this country, there being a majority of non-flowering plants compared with the flowering. The books are right.

Stanhopea oculata, Cattleya citrina, and Odontoglossum grande Culture (*Orchid*).—We fear you have not accommodation for the growth of these plants. The Stanhopea and Cattleya will not thrive in a greenhouse, nor will the Odontoglossum if the house is as airy as greenhouses generally are and should be. They will do very well if you convert your greenhouse into a close house, and keep it warm during the period the plants are making and perfecting their growth, and in winter they will do well in the temperature of a greenhouse if the atmosphere is dry. Keep the air of the house moist and the plants moist at the root—whether they are in baskets, on blocks of wood, or in pots, the compost should be moist—syringing them twice a-day or oftener, and the atmosphere should be kept moist by frequently sprinkling the floors, walls, &c. This treatment should be continued from the commencement of growth until it is perfected; then reduce the amount of moisture, and keep dry in winter. Do not overwater at first, but increase moisture with the increase of growth, and leave it off gradually.

Climber for the Back Wall of a Greenhouse (*M. H. R.*).—We do not know of anything that would thrive so well as, and look better than the gold and silver variegated Ivies, or you may have the variegated variety of Cobæa scandens; but the Ivies would look much better, associated as they would be with rockwork. The small-leaved kinds only should be planted.

Insects in Hotbed (*L. O. P.*).—The insects you sent are common mites or Acari, feeding on decayed vegetable matter, and not on living plants.

Cucumbers and Mushrooms (*Idem*).—You may have the Cucumbers as you propose, making for them a bed of horse-droppings or litter. The Cucumbers should be planted when your frame is at liberty owing to the bedding plants being cleared out, and you may in August wrap pieces of Mushroom spawn in a little dry hay and insert them 6 or 9 inches apart over the bed, and 3 inches beneath the surface; but you must not water the bed very much after the spawn is inserted, or it will perish. You may look for Mushrooms in about six weeks. We have, before soiling the bed for Cucumbers and Melons, placed pieces of Mushroom spawn, about the size of a hen's egg, 6 inches or so apart all over the surface upon the dung, having previously placed a thin layer of chopped straw over the bed, and after putting on the spawn covered it with a thin layer of the straw, and then with soil. This has been chiefly done in the case of beds for late Melons, and we have had splendid crops of Mushrooms in autumn and up to Christmas from the beds after the Melon plants were removed, the lights being protected from frost by mats and straw.

Gardeners' Royal Benevolent Institution (*Albert*).—Any person upon payment of £1 1*s*., annual subscription, may become a member; it is not limited to any age; under gardeners are of course eligible. For particulars write to Mr. Cutler, the Secretary, 14, Tavistock Row, Covent Garden, London, W.C.

Zamia elliptica Culture (*Idem*).—The plant should now be potted, using a compost of turfy loam, sandy fibry peat, and leaf mould, in equal parts, with a free admixture of sand. Provide good drainage, and place it in a temperature of from 60° to 65° at night, and from 75° or 80° by day, with sun and air, preserving a moist atmosphere to encourage growth. Syringe the plant overhead morning and evening, and when growth commences water copiously until it is perfected, then reduce the amount, still keeping the soil moist, but not nearly so much so as when growing. Afford a light and moderately airy situation. In other respects its treatment is not different from that of ordinary stove plants.

Making Asparagus-beds (*L. T. B.*).—In "Doings of the Last Week," page 282, you will find remarks to suit your case. Taking out a trench and filling with prunings and other rubbish, so as to secure good drainage, is a matter of importance, as in such stiff soils as yours, dampness at the roots is a great enemy to the Asparagus. If you cannot well do this we would trench the ground as deeply as the good soil goes, and pick up the subsoil and leave it. We would make narrow beds, by putting a few inches of the soil from the alleys on the bed. We would give no manure when trenching, but when the beds were set off we would place about 6 inches of rotten manure on the surface of each, and fork it in some 8 inches deep, incorporating it with the soil. We would plant young plants in the end of April, if 2 or 3 inches high, and give surface dressings of dung in summer, with dressings of burnt clay if we could obtain no sandy soil. Our advice is given on the principle, that in your case the plants will do best if the roots do not go far from the surface, and the deep stirring of the ground previously will prevent stagnant moisture. Even when a trench is made, we would keep all the dung, leaf mould, light soil, and burnt clay near the surface, say not deeper than 15 inches. We believe that by thus manuring the surface Asparagus can be grown in the stiffest soils. For simplicity nothing is better than single rows planted on the raised-ridge plan.

Succulent Vegetable (*X. X.*).—We do not remember your description given years since. If the vegetable is identical with Bruce's it would not grow in the open air hereabouts.

Vines Ripening their Wood Prematurely (*Constant Subscriber*).—We have read over your statement carefully, and as the Vines are 3 feet from the heating pipes, we do not think the pipes have anything to do with the Vines ripening their wood before the fruit is well set. As the Vines always come strong enough, break well, show well, and go on well until the wood ripens prematurely, we do not think that the border as to its constituents can be so much in fault, though certainly it would be advisable to have a drain 4 feet deep in front, and this we would make before attempting to lift the Vines and replant them. We think the premature ripening is more likely to be the result of a check to growth, either from too low a temperature or too much dryness in the border, especially in the four-feet inside the house. We would recommend, therefore, quite as many laterals being left. We think from 55° to 60° too low a temperature for an early house—say from 60° to 65° or 70°, and plenty of moisture at the roots about the time this ripening of wood generally takes place. Keep the outside border protected.

Circulation of Water in Quadrangular Pipes (*L. T.*).—You will have quite as good a circulation from your quadrangular pipes placed flat-wise, and more heat will be given off by them when so placed, as you will have so much more of an upper surface, and that will always be the warmest. We have some of the quadrangular pipes placed upright [] instead of as you propose flat ▭, and we found that from the quantity of water they held they were longer heating, and that when pretty hot at the top the bottom would be almost cool. We could not do as you (wisely we think), propose, place the pipes flat, but we did the best we could under the circumstances—namely, filled the pipes merely about half full of water, and then we had heat sooner, and the water heated the pipes above them. Place them flat by all means.

Bedding Pelargoniums (*Zonate*).—There are numbers of the ninety Pelargoniums named with which we have have had no experience as bedders, and several more which we do not even know. The following we can testify make good bedders:—Amy Hogg, Alice, Baron Ricasoli, Black Dwarf, Countess of Bective, Cyhister, Criterion, Clipper, Dr. Lindley, Diadem, Eleanor, Eugénie Mézard, François Desbois, Gem of Roses, Glow-worm, Helen Lindsay, Hardy Gaspard, Harry Hieover, John Veitch, Jeanne D'Arc, Indian Yellow, Lady of Loretto, Lord Palmerston, Lady Rokeby, Monitor, Mrs. Whitty, Madame Vaucher, Monitor, Milford Nosegay, Mrs. Wm. Paul, Napoleon, Orange Nosegay, Pink Pearl, Princess of Wales, Prince of Orange, Rosamond, Rival Nosegay, Rival Stella, Rubrocinctum, Stella, Spitfire, and Woodwardiana.

Seedsmen—Florists (*J. N. D., and an Old Subscriber*).—We cannot recommend any firm in particular. You must consult our advertising columns; write to several who there advertise, and ask for prices, &c.

Grapes Rusted (*J. Acton*).—The Grapes are affected with rust. Its cause is much disputed. We believe that it arises from the berries being subjected suddenly to a current of cold air after being overheated.

Names of Plants (*H. O. J.*).—1, Thyrsacanthus rutilans; 2, Vinca rosea. (*A Subscriber*).—No. 1 is Alonsoa incisifolia; all the others were insufficient for determination. (*Master John*).—1, Omphalodes verna; 2, Cornus mas; 3, Lotus; 4, Desmodium Skinneri, var. albo-lineatum; 5, Adiantum hispidulum; 6, Leucojum vernum. (*G. F. R.*).—The specimen is very much crushed, but we think it is Forsythia viridissima.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 23rd.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

HOUDAN FOWLS.

We have been requested to publish that which we know of this breed. We have kept them many years; they are very hardy, more so than the La Flèche and Crêve Cœurs, they bear close confinement without injury to their usefulness, and they are excellent layers. We believe they do quite as well here as in France. They are not kept so easily in bounds as a Cochin. We should not feel safe with less than a five-feet fence to confine them. Their disadvantage is, they do not sit, but in any country where eggs only are required we think most highly of them. They are never sick, they are much heavier than they appear to be, have grey square bodies, broad across the back, and are short-legged, five-clawed. Mr. Jacques thus describes the cock:—

"Roundish body, strongly built, of ordinary size, near the ground, resting solidly on strong feet; large head, half top-knot, bearded and whiskered, triple transversal comb; five toes on each foot. Plumage in the adult, speckled or splashed, black, white, and straw colour; in chickens, black and white only. No red feathers are admissible." Our very intelligent author proceeds to "general considerations on the breed." We quote literally:—

"This is one of the finest breeds of fowls, and nothing is richer than the aspect of a poultry yard composed of Houdans; but their good qualities are far beyond their beauty. Besides the small weight of bone, the quantity and delicacy of its flesh, it is admirably fecund and precocious. The cock chickens attain a large growth in four months, and easily, with ordinary care, put on fat and attain a large size.

"The pullets make magnificent poulardes, and among all breeds, this it is that shows the least difference in weight between the cock and pullet. They lay abundantly at an early age: the eggs are large and remarkably white. Pullets begin laying in January.

"This is truly a rustic breed, and is more easily reared than any other indigenous breed: it wanders less and pilfers less than most others. Like all large layers, this is but a very moderate sitter, yet the hen sits tolerably and is a good mother."

THE POULTRY CLUB.

Having been applied to for my subscription to the Poultry Club, before paying it I should certainly like to know what prospect there is of obtaining some return for my money. Hitherto it has been a very one-sided affair. The Club may have done good, which I am not aware of; the only benefit that I have derived from several years' subscription has been "The Standard," value 5*s.*: therefore, before continuing my subscription, I should like to know for what it is wanted, and what benefits are derivable from being a member henceforward of the Poultry Club? Perhaps some one may see fit to enlighten my darkness.—Bella.

FOOD FOR CHICKENS.

In last week's number of the Journal I noticed a communication from a "Weekly Subscriber" complaining of inattention on my part in forwarding the receipt for chicken food as per advertisement. I can only say that I have not in one single instance omitted forwarding either the receipt or the condiment as soon as it was possible; but we have a mail only three or four times a-week, per steamer, and if the weather be boisterous it is sometimes detained for as many days, thus causing a delay which may perhaps have been unaccountable and annoying to some of my numerous correspondents.

With respect to a "Weekly Subscriber," if his was an application dated the 23rd of March, and headed Kingstown, Ireland, having exhausted my stock of receipts, I was having a fresh supply printed, and was thereby delayed a couple of days. I forwarded one in due course, and the following day received another letter from my Irish correspondent complaining that he had not received the receipt, and demanding either it or the stamps. Having sent the receipt the previous day I did not think it necessary to answer this letter: hence, I suppose, the communication to your Journal.

If a "Weekly Subscriber" will send me a directed envelope, I shall be most happy to forward the receipt, and I will also send him a packet of chicken condiment by way of compensation for trouble and expense.—A. Le Cheminant.

BREEDING DARK BRAHMA POOTRAS.

I have read much in the Journal of late in reference to breeding Dark Brahma Pootras. I fear if we endeavour to come to the standard of the correspondents, we shall so mix and deteriorate this really good and handsome breed of fowls that in a few years we shall be unable to recognise our favourites in the wretched mongrels to which we shall have reduced them.

"Nemo" will have it, there are two schools of Brahma breeders and exhibitors, and he has been pleased to attach my name to one of these so-called schools, and hinted pretty broadly that I lean to the brown shade of colour in the hens rather than the silver-grey. This, I will grant; I will therefore try to give my reasons for the preference. When the chick of the Brahma first makes its appearance from the shell, what colour is the down on its tiny back? Is it not brown? I care not whether it is bred from birds professedly of the bluish-grey or not; this down gradually gives place to feathers, which in ground shade are of a dull whitish colour, minutely but distinctly pencilled throughout with dark pencilling. As they grow older, the pullets gradually develope themselves into the very shade (bluish-grey) which so many advocate; but wait awhile, watch those very pullets that possess that *true* shade, they moult again, and as hens their ground colour is brown, not a reddish brown, but a clear brown without the reddish tinge. This can but prove one thing—viz., that a brown ground shade is the correct and only colour. The red I abominate, and I maintain that it will never exist where due care is exercised in the selection of breeding stock.

Mr. Richard Teebay was the most successful breeder and exhibitor of Brahma Pootras in this country. I think he will bear me out in saying, there was no silver-grey about his hens; they were generally quite dark, but most beautifully and distinctly pencilled. This gentleman has told me himself that he likes to see a slight bronzing on the wing of the cock, as this helps to develope the desired shade of colour. The very gentleman whom "Nemo" professes to say belongs to the "silver-grey school," purchased the whole of Mr. Teebay's stock, and has exhibited hens quite as brown as any exhibited by me.

The gentlemen who desire to introduce this abortive silver-grey in Brahma hens will have many difficulties with which to contend. I will enumerate a few—viz., size, small; light breasts with muddled pencilling, or white breasts with no pencilling whatever; white heads, the pencilling only commencing half way down the neck hackle; bad combs; an insufficiency of fluff, and badly-feathered legs. They will also have to rear a large number of chickens in order to have a few comparatively good pullets, which will, in spite of every effort, moult to the natural colour, which they wish to avoid.

I have paid particular attention to Brahma Pootra fowls for the last fifteen years, having kept them in large numbers both in this country and America; and I must say I have made but poor use of my advantages of studying them in both countries, if I advocate a colour that is foreign to them.

In conclusion, I wish my fellow breeders and exhibitors to fully understand I do not wish to speak disparagingly of their fowls. All I want is fair play, competent judging, and let the judges prove to us what is the correct colour. I should not have written had not my name been mentioned, and hinted at pretty broadly by some correspondents. I have been, and still am, a successful exhibitor, as reference to the Journal will fully corroborate, and I fully intend to maintain my position.—Henry Lacy, *Lacy House, near Hebden Bridge.*

GAME FOWLS—VARIETIES OF COLOUR.

The different sorts of Game cocks have always been considered as showing the most beautiful variations of colour. The gorgeous, glossy, and royally-coloured red-eyed Black-breasted Reds, tinted and shaded with crimson, or nearly crimson, and blue (the royal colours), showing bright red, golden red, dark blue, steel blue, and dark green; and his rich red Partridge Brown, golden-hackled hen, present the highest type of feathered beauty of all; also, the Red Golden Cinnamon Black-breasted Red with his bright red eye, yellow legs and beak, and beautiful Cinnamon hens to match. The Black-breasted Red is undoubtedly the noblest of all the sorts as to his colour. Then the splendidly-shaped, fierce, and spirited Brown Red, with his rich dark brown red colour, and hard iron-like appearance, and beautiful, dark, hard-looking, fierce hens. The rich-coloured and often gaudy yellow or Birchen Duckwing; the high bred, neat, and chaste-looking Silver Duckwing Grey with his beautiful Silver hens; the keen-looking bright-red blood Pile, a parti-coloured bird, the type of quickness and activity; the spotless milk-white breed with their fierce bright-red eyes like the Pile; the bold, noble-looking, Brassy-winged Black or Sable, with his glossy jet-black hens; the hard, strong, and savage-looking Dark Silver Grey, looking nearly as hard as granite, so to speak, with the Dark Silver hens; the hardy and strong-looking Dark Birchens, or Bark Birchen Greys, with their dark hens; the beautiful yellow-hackled Blue Dun with orange shoulders in the cock; the beautifully-tinted Red Dun or Ginger Blue Red; the curiously-marked Polecat or Dark Tawny, often light-coloured underneath the body; the gay-coloured Spangles and Red Furnaces; the sharp, fierce, and fiery Ginger Reds, as quick as the keenest Pile, and also the type of quickness and activity; the very yellow Yellow Birchens; the neat Mealy Grey breed; the tufted and muffled breeds so seldom seen; the "true Black Reds," dark port-wine coloured, bred from Blacks and Black-breasted Reds (the term "Black Red" being wrong for Black-breasted Reds), the homely hen-tailed cock with his partridge short feather like his hen; and many other handsome crosses and mixtures, one of which is the spirited cross between the Brown Reds and Blue Duns, throwing cocks ginger-breasted with blue thighs, wings, and tails, and yellow-hackled blue hens. (This cross beats all colours in fighting in some places, not excepting Brown Reds and Dark Greys, though not so hard as these, but faster birds. The Dark Grey also crosses well with the Blue Duns for fighting. Blue Dun cocks with Brown Red hens produce most of these, but the Brown Red cock and Blue hen is most used.) All these colours present a picture of all the variations of feathered beauty and colour that no other poultry can possibly present, surpassing even Pheasants of sorts and colours. No wonder amateurs are fond of their Game breeds, long may they be so! The above-named cross is the "Ginger-breasted Orange Blues," called Birchen Blue Reds, or Brassy Blue Reds.

I omitted the following in my foregoing notes. Many breeders say that in crossing colours the most cock chickens take after the hens, and the most pullets after the cock. My own experience and that of my neighbours is exactly the reverse of this. Most of my cock chickens in crossing took after the cock, and most pullets after the hens, in all cases; of course, supposing the cock to be equal to the hens in strength of blood and colour.

A cock chicken is a chicken until his first Christmas, if a spring-bred bird, a "stag" after his first Christmas, and a cock after his second Christmas. A pullet is a chicken until she lays her first egg, and a hen after her second Christmas, a pullet until that time.

In crossing breeds the cock chickens take most after the harder and stronger strain of the two, whether the hens or cock be of the harder and stronger sort; the most pullets being of the softer and weaker strain of the two used.—NEWMARKET.

BEE-KEEPING IN RUSSIA.

(Translated from the German.)

THE gigantic Russian empire comprises, besides the Russians, a great many other nationalities, which are partly scattered and mixed in the whole empire; and other nationalities than the Russian partly prevail in certain districts; but each nationality has generally its peculiar customs and manners, as also, for the most part, its own modes of tilling the ground, rearing cattle, &c. It is also naturally to be expected that the bee is there kept in different ways by the various nationalities, either more rationally or irrationally.

I have travelled pretty much through the whole of Russia; at least, I have visited many governments or provinces of all the four cardinal points, and I find that there is a difference in bee-keeping in the north and in the south, in the west and in the east; but everywhere throughout Russia, bee-keeping is mostly in the hands of the peasants and the clergy. There are few clergymen, in Russia proper at least, who do not keep bees. Also, in many monasteries bees are kept by the monks. In Poland alone, and especially in the provinces on the Baltic, clergymen seldom occupy themselves with bees. Next to the peasants and clergy it is the merchants of the towns, nay even of the largest, as for example Moscow, who keep bees, whilst schoolmasters and government officials do not occupy themselves with bee-keeping at all, as these persons consider it beneath their dignity. Artisans also do not keep bees. There are but very few landed proprietors who possess an apiary, and those that do, attend not to it themselves, but leave it to their inspector or starosta—*i.e.*, elder, who is always a peasant, and is chosen from those who can be most relied on. Only in the provinces on the Baltic, which are for the most part inhabited by Germans, and where the landowners, with the exception of a few Poles, are exclusively Germans, they often take part in it. But bees are kept everywhere, even in the northern government of Archangel, and mostly on a large scale. It is but seldom we meet with a bee-keeper, unless he be a beginner, who has less than a quarter of a hundred hives. They are generally owners of at least fifty to one hundred stocks—nay, towards the south-east, for example the government of Orenburg, even of five hundred to one thousand stocks. Bees are most extensively kept in the eastern governments, in those of Isaratoff, Orenburg, Isimbirsk, Kasan, and Nishay Novgorod, and also in the eastern provinces of Bessarabia, but especially in Podolia, Wolhynia, and particularly in Minsk.

In the whole of northern, middle (excepting the deserts of Tula, Orel, &c.), and eastern Russia, the bees are kept in klotzbeuters,* always in the form of ständers.† In southern Russia where there is no wood, bees are only seen in straw cylinders which exactly resemble our German ones. Likewise, also, in Poland, mixed however with klotzbeuters. In both districts the lager‡-shape prevails. In the Polish provinces of Ismolensk and Witebsk, as well as in the north-western governments of Pskow, Novgorod, and Petersburg, which are inhabited by Russians, one sees only klotzbeuters, as in the north and east, but almost wholly in shape of lager-hives. The ständers, which are very small, are used only for hanging in trees in the forests near the apiary in order that swarms which fly away may enter these hives, which they almost always do. In the Baltic provinces, however, the upright klotzbeuters are the most common bee-hives; also in southern Finnland, at any rate near Abo. Only in southern Curland, on the Witebsk boundary, did I meet with the lager-form.

But the klotzbeuter-lagers in Russia are not, as in many districts of Germany, placed horizontally; one side is always considerably higher than the other, being raised on poles or stones. The swarm in this case, of course, begins comb-building in the highest part of the hive. The straw cylinders, however, mentioned as being used in Poland, in southern Russia, and in the districts of the northern deserts are very seldom placed, as in Germany, in special bee-houses, but for the most part single, a distance of several paces being left between the hives, and each being thatched with straw or roofs of reed, like little houses. The standing klotzbeuters never have a wooden roof throughout all Russia; they are always covered in but a rough manner with the bark of birch trees or firs, the bark being weighted down with stones that the wind may not blow it off.

In the civilised provinces—*i.e.*, the Baltic provinces and Poland proper, which have more or less of European culture, bees are also kept in magazine-boxes by some, and recently even in Dzierzon hives, but they are very few, and scarcely worth mentioning. But in Russia proper no one knows Dzierzon, not even by name, excepting only the professors of zoology. Lately, however, there has appeared a Russian work on bee-keeping, by Professor K——, of the Gorigoretzk Agricultural Institute, originally a German, who mentions something about Dzierzon and Von Berlepsch, but rejects the hives of both these gentlemen as "impracticable," and recommends his own, a depraved magazine-hive. Under such auspices Dzierzon's method certainly cannot find its way into Russia proper.

As to the management of bees, it varies much in different districts. Throughout the whole of the eastern part of Russia they adopt the swarming system, but manage it differently from the Germans. First and second swarms which issue early are planted singly, and wintered as stock hives. As soon as the desired number of stocks are obtained all the swarms which issue afterwards are formed into gigantic colonies. From three, four, five to ten swarms are united in a huge klotzbeuter, so that a swarm thus made weighs from 10 to 20 and more lbs. If several swarms do not issue in one day, so that such a gigantic stock may be made at once, then swarms are added to the young stock one by one. In doing this, the bee-keepers are not particular whether first swarms are united with first swarms, or first swarms with second swarms. The swarms which are to be united are well sprinkled with honey-water, and fumigated very strongly with the smoke of rotten willow wood. The superfluous queens are never removed previously; this is left to the bees. It is strange that in this irrational proceeding but few bees are killed, which is, perhaps, owing to sprinkling them well with honey-water and fumigating them strongly. In autumn, generally in October, these colossuses are sold to the so-called "bee-slaughtermen" (literal translation from the Russian, Pscheloboitschik), who kill them with brimstone, and then prepare an emulsion of honey, brood, bees, and the excrements of cattle with which the interstices of the hives are closed, and sell this mixture in casks of 20, 40, to 60 lbs. and more to merchants in the towns. Parent hives, which are too light, and which have not gathered sufficient food for the long winter, the owners do not sell to "bee-knackers (flayers)," but cut out the combs and let the bees fly where they like. For the bee-keeper in this district thinks it a great sin to kill bees with his own hands; but if he leaves it to the bee-flayers, he, according to his own opinion, has washed his hands of it. Late in the autumn, as soon as snow has fallen, all the stocks are taken into a dark room which is distant from the dwelling-house and not heated, or into some locality built for this particular purpose; the entrances are loosely stopped with straw, and the outside of the building is covered with straw and brushwood. The bee-keeper does not now look after his bees until spring. The stocks are never fed, either in winter or in spring. They leave them always honey enough to have still plenty in the spring. In spring, the second day after having taken out the stocks, which are placed singly in the garden or in the woods, they are examined. First, the lowest door is opened, the dead bees are swept out, and those combs which may have become mouldy are removed, but only those which are very mouldy; for, if possible, no cell of good comb is damaged. The next day, or not till the third day, the head (top) is examined, where

* Hives formed of the hollow trunks of trees.
† Upright hives, having generally two or more compartments one above the other.
‡ Horizontal.

likewise the mouldy comb only is removed, but only in the very worst cases, for the bee-keepers there do not like to cut the top. The loss of queens is generally not perceived until a few days after, when the bees by degrees begin to dwindle away, and bees of other stocks plunder the honey, and then the combs of the queenless stocks are cut out. Throughout the whole empire stocks which have lost their queens are treated alike. In summer the whole care of bees is limited to the temporary opening of the lower door in order to remove the moth larvæ which may have nested there. During the swarming period, which does not begin until the second week in June, a person—generally a young girl or an old woman—is continually watching during warm and dry weather. Everywhere around the stocks several wooden blocks which have been charred all over are fastened on poles that the swarms may settle on them and not fly away. The swarms indeed select these blocks much more frequently than a shrub or tree, but they nevertheless very often fly off into the woods. When putting the swarms into the swarm-basket, the latter is first rubbed with a plant which is there called the deaf nettle, but which is the Leonurus cardiaca, Linn. The bees are said to like the smell of this plant, a fact of which I have convinced myself.—Edward Assmuss.

(To be continued.)

FRAME HIVES—FEEDING BEES.

I have two stocks, swarms of last year, in Woodbury-hives of eight and ten frames, which are so constructed that the hives can be turned upside down if necessary, without fear of the frames shaking. I wish to obtain some honey, if possible, and swarms artificially, as I am occupied with my business during the day. The hives that I have to swarm them in are entirely different from those of Mr. Woodbury, but still frame hives; therefore I am debarred the usual advantage of them. How would it be best for me to act in this case? The food which I give my bees—viz., sugar and water, in bottles always candies and stops the mouth up. How is this to be remedied? and how may I know when a hive has swarmed?—J. C. A.

[We look upon "duality" in the construction of frame hives with quite as little favour as the House of Commons regarded the "dual vote." We should therefore on no account admit any hives into our apiary the frames of which were not interchangeable with all the others.

The syrup which you have been administering to your bees is either overcharged with sugar, or the network which covers the bottle-mouth is of too fine a mesh. We put three parts sugar to two of water, by weight, and use an open leno, the meshes of which are fully one-sixteenth of an inch in diameter. A sudden decrease in the population is the first indication of the escape of a swarm. Whenever this is observed, the fact of a swarm having issued may be readily either verified or disproved by an examination of the hive's interior.]

RANGE OF BEES' FLIGHT.

This is a subject of great importance to bee-keepers, as it has been supposed that bees fly only about three miles when collecting honey, consequently there has been a fear of overstocking an apiary.

Having ascertained that there were no bees on Kelley's Island (Lake Erie), in the spring of 1866 we established an apiary of the Italians there, for the purpose of rearing pure Italian queens and ascertaining the flight of the Italians for food. In less than a week after they commenced flying they were busily at work on the other end of the Island, more than five miles distant from the apiary. This season we shall carry some of them (in a hunting box) out on the water, and ascertain how far they can be induced to work from the hives. We are of the opinion that they will not fly as far across the water as on the land, where there is a continuous supply of flowers to call them from the hives. We shall report further discoveries at the close of the season.—W. A. Flanders (*Prairie Farmer*).

OUR LETTER BOX.

Gapes—Guinea Fowls (*J. Worsfold*).—To cure the gapes give each chicken a piece of camphor daily, about the size of a small pea, and put a lump of camphor into the water they drink from. The hen Guinea fowl utters the peculiar "Come-back" cry. The cock only utters a whining noise.

Hen Eating Her Egg (*Blanche*).—The only course to adopt is to watch her whilst laying, and to remove the egg as soon as it is laid. Have artificial eggs made of chalk or porcelain for nest eggs.

Accrington Poultry Show.—Messrs. S. & R. Ashton, Mottram, Manchester, inform us that they were awarded first prize in Gold-spangled Hamburghs at Accrington Show. It was omitted in the report we received.

Dorking Cock's Comb Bleeding (*A. B.*).—Cauterise the wound, and it will stop the bleeding. We have used lunar caustic for this purpose very freely and with great success.

Failure of Fowls and Turkeys (*L. T. B.*).—Everything seems arranged to go right with your poultry, yet it is evident all goes wrong. While there is no royal road to success, there is no reason on the other hand why failure should be the rule. Do you keep fowls and Turkeys together? If you do, separate them. Have your houses wooden, stone, or brick floors? If they have, remove the floors or cover them with 6 inches thick of earth and gravel. When your chickens are hatched, do you keep them close together? If you do, divide and scatter them about. It is most likely more eggs will come out under the sitting hen if they are moistened for some days before hatching. The chickens that die in the shell die from lack of moisture. When the chickens are out, do not disturb them much for the first twelve or eighteen hours? Then take them as far away from other fowls as you can. Choose for them a dry spot on a slope in the park, if under a bayrick so much the better. Let them be where they will be exposed to the sun, but sheltered from the wind. Place thus your hens and chickens as far apart as you can consistently with their safety. Provide them with beer to drink, road-grit or dust to bask in, and plenty of good food. Above all, keep the hens shut up as long as the chickens require it, certainly from seven to ten weeks; if longer so much the better. This is good for fowls and Turkeys. At this time of year when the mornings are very cold, often frosty, the hen drags either or both of them about till they are completely chilled, they then die with every appearance of rear.

Ducklings and an Artificial Mother (*Henwife*).—We have seen Ducklings reared in the artificial mother of Minasi's incubator, but we do not approve of glass above them. They should *not* have sufficient water to dabble in, and they may be fed on ground oats and meat chopped fine.

Call Ducks (*L. T. B.*).—Your Call Ducks die like other Ducks that are allowed their liberty. Old Ducks fancy their young can follow profitably wherever they themselves go. Towards evening they take their young, only a few hours old, under steep often beetling banks in search of the evening fly. One by one they leave the brood behind. Hens are the most successful mothers because they avoid the water. If you rear under Ducks we advise you to let the old bird sit in a pigstye or place where she cannot get at any water, and yet where the inequalities allow of sufficient moisture to enable them to feed and drink. When they get older, and before they are allowed their liberty, let them have every day a large shallow vessel. Let the bottom be covered with a large sod of grass, on this lay some oats, meal, and gravel. Cover the whole with 1 inch of water. They will thrive well.

Brahma Pootra Pullet Lame (*Brahma*).—We know not to what to attribute the lameness of your hen. It may be accident, and from the suddenness of its appearance we should think it was, or it may be like many of our own ailments, the origin of which cannot be detected.

Non-payment for Poultry (*E. C. Boville*).—It is not a case for our columns, but for the County Court. Employ a solicitor without delay.

Eggs Chilled (*W. W. W.*) —As the eggs were only sat upon three or four days, their being allowed to become cold as you describe will not interfere with their production of chickens.

Preserving Eggs (*A. E. P., &c.*).—The following is from the "Poultry-keeper's Manual:"—"Have large boxes or barrels thoroughly lined inside with paper; put them in a cool but dry place. A layer of fine white salt an inch thick should cover the bottom. New-laid eggs should be laid side by side on this salt, and all vacant spots or places should be carefully filled with it. Successive layers of eggs and salt fill the box, which is then very tightly screwed down, and paper pasted over the joints. Fine white salt is preferable. On the 1st of August, 1849, M. Jacques opened a case of six hundred eggs, preserved in September, November, and December, 1848—that is to say, eleven months after they were put away; although they no longer possessed the delicate flavour of a new-laid egg, they were well-kept, and well-tasted—good enough for any domestic use."

Runt Pigeons (*C. S.*).—By all means try Runts, and send us your experience. They are noble Pigeons, and ought to be thought more of. Some years since we had Spanish Runts, and very large and long-bodied they were. They brought up their young ones well, and we did not find them delicate or liable to disease. Try to avoid breeding in-and-in; start with breeds that are not related to each other, and by exchanging, or other management, prevent near relations being paired. If you succeed in making Runts popular you will confer a national benefit, as many would then keep them for the table, and be proud of their size, as Dorking-fanciers are of the legs of their birds. Have roomy nests, low perches, and you must not expect much flying from them. A low outhouse, if safe from rats and cats, makes a good home for Runts.

Feeding Bees (*Bee-keeping Subscriber*).—There does not appear to be any pressing necessity for immediate feeding, but if the present broken weather continues, the administration of a moderate quantity of food may not be unadvisable.

POULTRY MARKET.—April 24.

We have a great scarcity of good young poultry. Trade is deplorably bad, or there would not be sufficient to supply London. There is not an average quantity at market.

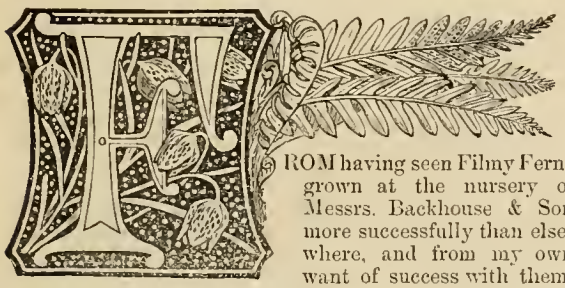
From observations taken near London during the last forty years, the average day temperature of the week is 61.5°; and its night temperature 39.2°. The greatest heat was 84°, on the 6th, 1862; and the lowest cold 21°, on the 8th, 1855. The greatest fall of rain was 1.26 inch.

CULTURE OF FILMY FERNS.



FROM having seen Filmy Ferns grown at the nursery of Messrs. Backhouse & Son more successfully than elsewhere, and from my own want of success with them, except when covered with bell-glasses, I was led to take an interest in them, and to try to find out wherein the secret of their culture rested, and not without success.

Growing Filmy Ferns under bell-glasses, or glass shades, is, no doubt, the only eligible mode of culture where the atmosphere is only moist enough for greenhouse or stove plants, and where they are kept in pots or pans along with other Ferns; but it interferes so much with their being seen to the best advantage, that it is only tolerable where the means do not permit of their being otherwise cultivated. I am persuaded that with but a slight expenditure we might have these plants in beauty at any time. Those who have ferneries in which the Ferns are planted out on rockwork will not experience any difficulty in the culture of Filmy Ferns if they provide for them a cave or well, with water dripping from the roof or top, by which the atmosphere around, and the stones, on which the rhizomes run, will be kept constantly moist. So numerous, however, are the species now that a house may be specially devoted to their cultivation, and that I shall first proceed to notice.

The tropical species thrive well, write Messrs. Backhouse, "in a low span-roofed house, heated by hot water circulating in open brick tanks, and slightly shaded;" whilst the New Zealand, Chilian, and Tasmanian species "succeed well in our ordinary (cool) fernery without any glass shades: the glass roof being externally covered with a thin coating of white paint, and the atmosphere kept constantly humid."

To make a digression, which I hope the reader will pardon, I think that for Ferns to be seen to the best advantage they should be associated with kindred subjects. For instance, where there is a rockery of any considerable proportions it should be occupied with Alpines, and near it might be the hardy fernery, having the northern aspect of the rockery. I would here introduce ferneries of glass for the more rare and less hardy kinds of Ferns, having first a cool house for the best of the hardy British and exotic species and varieties; then a house for Ferns from temperate climates, and large and lofty enough for tree Ferns, these being disposed in irregular beds on the ground, and not on raised rockwork: and a third house for species from hot countries. In each of these houses I would have a recess of sufficient size to allow of a person standing in it and viewing the plants, and having an entrance as large as a fair-sized door. I would not use a brick in the construction of the houses, but would build the walls of limestone rock and large pieces of sandstone, and I would use no glass except for the roofs, which should extend over every part, even to the recesses for the Filmy Ferns. Any difficulty in making the opening in the walls could be surmounted by filling them up with small pieces of rock and mortar. I would have nothing objectionable to the eye but the necessary doors, and places for heating might by a little care in the disposition of the rockwork be readily arranged. The above would be a more natural and agreeable disposition of ferneries in gardens than that generally adopted, and it would not be more costly, whilst the wants of those kinds thriving outside, as well as Alpine plants, which of late years have been much neglected, would be provided for.

Filmy Ferns are the least exacting of all plants. They require an atmosphere which is constantly humid, an open porous soil, and a moderate amount of air. The above conditions cannot be secured in ordinary ferneries, and I therefore advocate devoting specially to Filmy Ferns either part of the house or a small house. The latter I would make in the ground, or against the side of a bank, covering it with rough plate glass. The interior fittings should be formed of rockwork, employing gritty sandstone, and if moss-covered all the better. The floor should be formed of rough stones, and the heating apparatus should be hot-water pipes passing through open tanks made of bricks and cement. The tanks may be easily hidden by rockwork. The best stock bricks, or, still better, blue fire-bricks, should be used. Provision must be made in the centre of the glass roof for admitting air, which should not be given at the sides nor immediately over the plants, and never in excessive quantity. If a division is made with rockwork, or the fernery is narrowed in the middle, a doorway only being left, one end may be used for the tropical species and the other for those from temperate regions, requiring artificial heat only in winter to protect them from frost, for which purpose two hot-water pipes all round will be ample: these may be hidden by rockwork, and should never be made very hot. Unless the house is more than 12 feet wide, a brick tank, 1 foot wide and 1½ foot deep, with two four-inch hot-water pipes in it, all round the house, will be ample for the tropical species; for the house being against a hill, and in a manner in the ground, the temperature and humidity will be more equable than where the house is above ground. If there is a shallow stone reservoir in each compartment, by keeping it full of water the requisite degree of humidity may be more easily maintained than where such does not exist. In the arrangement of the rockwork it should be remembered that all the species are not the same in their requirements; some parts of it should be made prominent, in others there should be recesses or nooks, and some must be close to the glass, and near the points of air-giving. If this be done with taste the house will be everything that could be desired, for there will be places more shady than others, some airy, and some where the atmosphere can be kept more close and wet than in others.

As to soil for filling up the interstices in the rockwork and for planting in, it is hardly necessary to do anything in the matter, for Filmy Ferns do not require rich soil. We may employ a compost of equal parts of turfy brown peat, such as is used for Orchids, and chopped sphagnum or bog moss, the peat being broken with a spade, adding to it an equal quantity of sand or broken gritty rock from the size of a hen's egg to that of a pea, the whole being well mixed and incorporated, and placed in the interstices and hollows. In any prominent position more soil should be used, and, omitting the sphagnum, such kinds as Todea pellucida may be planted there.

Previous to planting, the house should be syringed twice daily, and every part made thoroughly moist. The planting is difficult to describe; for some kinds it merely consists in placing them on a ledge of rock, for others in putting them in a crevice and laying a few pieces of grit around them to maintain them in position, whilst for others, again, the trunk of a tree Fern is set on its end or laid on its side in a corner; others must be furnished with soil beneath and around them, but in no case should they be buried or covered. When in position they should be sprinkled overhead twice daily, and every stone both of the floor and rockwork ought to be kept constantly wet. It is not possible to have a syringe with too fine a rose, for water cannot be sprinkled over them too finely. Some kinds are impatient of water on the fronds, these will be named hereafter. The stones and every available surface being sprinkled twice daily from the tanks or reservoirs in the centre of the houses, and the water being directed with force against them, further watering may in most instances be dispensed with, as the moisture will run from the rockwork to the roots of the Ferns, and be dispersed over their fronds in the form of a thick mist. If there be sufficient moisture it will hang from the points of the fronds, which will be "covered with minute dew-like drops every morning," as Messrs. Backhouse describe. The amount of moisture, as shown by a hygrometer, is complete saturation, and if not so much it is too dry for Ferns of this class. If the rock and floor be kept wet the amount of moisture will not be far deficient.

As to air-giving, that is equally difficult of description, for air must not be admitted so freely as in the case of plant-houses generally, and yet it is essential. There must be no cold draughts, and yet air must be afforded daily, and, indeed, constantly, but in very moderate quantity. Anything approaching a confined atmosphere is injurious, for though Filmy Ferns flourish in humidity, they also delight in fresh air. Air, then, should be given in such a quantity and manner as not to dry the atmosphere more than can be avoided. More air is, of course, necessary by day than night, and in this respect they require nearly if not quite as much air as Ferns generally, only the ordinary kinds are less susceptible of its drying influence. Give them air if you do not wish the fronds to become brown before they are well developed, at the same time see that it does not render the atmosphere deficient in humidity. The amount of air may be liberal if the necessary humidity is maintained.

Temperature is an all-important point; the stove kinds generally will be found to do well in a winter temperature of from 50° to 60°, increasing with sun or the heat of the external air to not more than 65°, and this temperature should be maintained from October to March. In March the temperature should be slightly increased, and go on gradually increasing until from 75° to 80° be attained, which may occur by the middle of May, or from that time to June. At this temperature the house should be maintained to the end of September, when its heat should be allowed to decline so as to fall to a minimum by the close of October. This temperature will be sufficient for the majority of the West Indian and tropical species, but a few require a greater degree of heat; still they may be accommodated in one house by having the warmest places assigned to them.

The kinds from Chili, New Zealand, and Tasmania succeed admirably in a winter temperature of 40° as a minimum, fire heat being only employed to prevent the temperature from falling below that point, and the general winter and summer temperature will be regulated by the external air; this being the case, the minimum in summer will be 60°, and the maximum between that and 80°, but generally about 70°.

As regards shade, I have found nothing equal to a thin coating of white lead paint put on when the external surface of the glass is thoroughly dry, and dabbing the paint before it dries with a painter's dust-brush. This shading I find ample.

I have already stated that some kinds are impatient of water on the fronds, and some require more air than others, whilst others differ in the matter of humidity and shade, and these points I hope will be gleaned from the following list of species, which is based on the catalogue of Messrs. Backhouse.

Stove Species, requiring a temperature of from 55° to 60° in winter, and one of 80° in summer:—

Trichomanes anceps, 1½ to 2 feet high, forming tufts. West Indies. Very humid and rather close atmosphere. This is one of the best. Temperature* 55° to 80°.

T. Bojeri, very small, requiring to be grown on the trunk of a Palm tree or tree Fern, which it is said to clothe in the Mauritius. The atmosphere requires to be very moist. It should have a position in the warmest part of the house. Temperature 60° to 80°.

T. attenuatum, a fine species, closely resembling T. alatum, found on trunks of trees in the West Indies, and doing well on them in this country, as also in chinks of rock. The atmosphere must be very humid and somewhat close. Temperature 55° to 80°.

T. alatum, 1 foot high, tufted, growing on trunks of trees like the last, and will thrive on blocks of wood or in crevices of rock. Temperature 55° to 80°.

T. achilleæfolium, handsome, tufted, 1 to 1½ foot in height, requiring a very humid and close atmosphere. This needs to be placed in the warmest part of the house. Temperature 60° to 85°.

T. Bancroftii small and tufted, 3 to 5 inches high. To be kept humid but airy.

T. crispum, 18 inches high, tufted and handsome. Very humid but airy. Will do in a cool part of the house. 55° to 75°. West Indies.

T. crinitum, tufted; requiring the soil to be very well drained, a humid atmosphere, but no water on the fronds. It should have a cool situation. 50° to 75°. West Indies.

T. elegans, 9 to 12 inches, needing the warmest part of the house, and to be kept very humid and close. 65° to 80°. West Indies.

T. Filicula, creeping. It requires to be kept very humid and somewhat airy. Afford it a warm situation. 65° to 80°. Mauritius.

T. javanicum, tufted, 9 to 12 inches high. A very humid and rather close atmosphere. Java and Philippine Islands.

T. floribundum, requires a clayey soil mixed largely with silver sand and a little peat or leaf mould, and to be kept very humid and close. Tufted, 1½ feet high, and fronds very noble in appearance. Should have a warm part of the house. 65° to 80°. West Indies.

T. fimbriatum, allied to T. Kaulfussii, needing very moist soil, and a humid and somewhat close atmosphere. 55° to 80°. West Indies.

T. Kaulfussii, tall (1 foot high); soil firm and very moist; atmosphere humid and rather close. It should have the warmest part of the house. 65° to 85°. West Indies.

T. Kraussii, small and creeping, requiring to be grown on a piece of the trunk of a tree. It requires to be kept humid and airy, and will succeed in a cool part of the house. 50° to 75°. West Indies.

T. Luschnatianum, a climbing species, rambling over mossy rocks, and succeeding in a cool part of the house. Humid and rather airy. 55° to 75°. Brazil.

T. muscoides, creeping, needing a warm situation, and a humid and rather close atmosphere. 65° to 85°. West Indies.

T. membranaceum, creeping, requiring a warm situation, and a very humid and rather close atmosphere. 65° to 80°. West Indies.

T. pluma, as yet very rare, erect, 1 foot high: requires to be grown amongst decayed logs of wood and moss, and kept very humid. This will do in a cool part of the house. 50° to 70°. Borneo.

T. pyxidiferum, creeping, growing on trunks of tree Ferns or stems of Palms. Humid and rather close. 55° to 75°. West Indies.

T. reptans, very small, requiring the stem of a Palm or tree Fern to grow on, and to be kept very humid and rather close. 55° to 80°. West Indies.

T. rigidum, 1 foot high, tufted, requiring to be kept very humid but airy. 55° to 80°. West Indies.

T. rhomboideum, resembling T. javanicum, and, like it, from the Philippine Islands; 1 foot high; needing to be kept very humid and in the hottest part of the house. 65° to 85°.

T. scandens, creeping; needs to be grown on the stem of a Palm or tree Fern, and to be kept humid but airy. It will do in the coolest part of the house. 50° to 70°. West Indies.

T. rupestre, tufted; grows on bare wet rocks. It should have the hottest position. 70° to 80°. Borneo.

T. sinuosum, climbing on trees in the West Indies, and requiring to be grown on logs of wood, and to be kept very humid and rather close. Will do in a cool position. 50° to 75°.

T. thujoides, 1 foot high, tufted. To be kept very humid and rather close. 60° to 85°. Mauritius.

T. spicatum, to be kept very humid and rather airy. 55° to 75°. West Indies.

T. trichoideum, creeping, requiring to be kept very humid and rather close. 55° to 80°. West Indies.

Hymenophyllum asplenioides, requiring to be grown on mossy rocks or logs of wood; to be kept very humid but rather airy, and watered freely. 55° to 75°. West Indies.

* The temperature requisite for each kind is here stated, as it may be useful to those who wish to grow them in Wardian cases, for which these plants are well suited. The temperatures are as given by Messrs. Backhouse & Son.

H. abruptum, should be grown on mossy rocks or trunks of trees, in a cool, humid, and shady position, and well-ventilated atmosphere. 50° to 70°. West Indies.

H. ciliatum, grows on mossy rocks or trunks, and should be kept very humid and rather close. 50° to 75°. West Indies.

H. hirsutum, grows on logs of wood, and should be kept very humid but airy, and ought not to be watered over the fronds. 55° to 80°. West Indies.

H. hirtellum, a fine Jamaica species, which requires to be kept very humid and airy. 50° to 80°.

H. Plumieri, to be kept very humid and airy. 55° to 80°. West Indies.

H. sericeum, grows on rocks in the West Indies, and thrives best on them in this country. It should be kept very humid but airy. It dislikes water on the fronds. 55° to 75°.

Greenhouse Species, requiring a temperature of 40° in winter:—

Hymenophyllum æruginosum, growing on rocks and mossy logs; should be kept humid and rather close, and watered freely, but not over the fronds. 40° to 65°. New Zealand.

H. candiculatum, needs a compost of decaying wood or mossy logs, and a very humid and rather close atmosphere. 40° to 65°. Chili.

H. chiloense, on mossy rocks and logs, and to be kept very humid. 40° to 65°. Chili.

H. crispatum, needing the trunk of a Palm or tree Fern, and to be kept very humid but airy. 40° to 65°. New Zealand.

H. cruentum, should have a mossy log of wood, a very humid atmosphere, and a rather shady situation. 40° to 65°. Chili.

H. demissum, 1 foot high, requires to be kept humid but airy. 40° to 65°. New Zealand.

H. dichotomum, requires a mossy log of wood, a very humid atmosphere, and a shady position. 40° to 65°. Chili.

H. dilatatum, needs a compost of decaying wood, leaf mould, and moss. A very humid rather close atmosphere, and a shady position. 40° to 65°. New Zealand.

H. flabellatum, grows on the trunks of tree Ferns or of Palms. It should be kept very humid, and rather airy. 40° to 65°. Tasmania.

H. flexuosum, needs the trunk of a tree Fern or mossy log, and must have a very humid and rather close atmosphere. 40° to 65°. New Zealand.

H. fuciforme, 18 inches to 2 feet high. Needs to be kept very humid and rather airy. 40° to 65°. Chili.

H. polyanthos, requires to be kept humid and airy: it does not thrive under a glass shade. 40° to 70°. New Zealand.

H. pulcherrimum, needs a very humid atmosphere. 40° to 65°. New Zealand.

H. rarum, very like H. tunbridgense, needs to be kept very humid but airy; avoid wetting the fronds. 40° to 65°. New Zealand.

H. scabrum, must be kept very humid and rather airy. 40° to 65°. New Zealand.

H. tunbridgense, grows on mossy rocks or in chinks of rock, and should be kept very humid and rather airy: avoid wetting the fronds, as they quickly become discoloured. 40° to 65°. Well known to be a British species.

H. unilaterale (Wilsoni), grows on mossy wet rocks, and should be kept very humid but airy. 35° to 60°. British species.

Trichomanes elongatum, 6 inches to 1 foot high. Tufted. Requires a very humid and rather close atmosphere. 40° to 65°. New Zealand.

T. exsectum, creeping, on ledges of rock. Must have a very humid and rather close atmosphere. 40° to 65°. Chili.

T. radicans (speciosum), flourishes on rather mossy moist grit. It needs a very humid and rather close shady atmosphere. 40° to 70°. Ireland, also Madeira.

T. radicans Andrewsii. The fronds of this are lanceolate instead of triangular-ovate as in the species, and it fruits freely.

T. reniforme, creeping on mossy rocks. A very humid and rather well-ventilated atmosphere. 40° to 70°. New Zealand.

T. venosum, should be grown on the trunk or part of a tree Fern, and must be kept very humid but rather airy. 40° to 65°.

To the above may be added the three Todeas—viz., arborea, australis, and pellucida, which should be planted in peat, pieces of sandstone or grit, a little leaf mould, and sand, affording a rather airy situation, and no water over the fronds.

A correspondent wishes to know the reason of the fronds of Filmy Ferns becoming brown. This, as far as I have experience, is the result of variable humidity, they being sometimes dripping wet and at others quite dry. Excessive moisture will, in many cases, cause the evil, especially when there have been heavy syringings, which should be avoided, as water ought never to fall upon them with force, but always like dew; at the same time the atmosphere should be kept constantly humid. Some kinds will not endure much syringing over the fronds, and all are better if the requisite amount of moisture can be kept up without it; but in many cases this cannot be done. A frequent cause of the fronds becoming brown, is their being stifled under glass shades, the moisture remaining on the fronds from morning to evening. A little air would in such cases make all right, but if air be admitted excessively, the young fronds will perish before they unfold, and the same result, along with browning of the fronds, takes place in a very close atmosphere. Filmy Ferns like most other plants require fresh air, moisture, and water, but the air must not reduce the humidity of the atmosphere, which must be constant, and water should not be allowed to lodge but pass away freely, it being as freely replaced.

I may now offer some remarks on the culture of Filmy Ferns in ordinary ferneries. These seldom possess sufficient humidity, but the plants may be grown in them in cave-like recesses made for the purpose, and which may be formed of grit or sandstone. These should not be deep, otherwise they will be too gloomy. If a pipe can be carried over the recess, so that by opening a tap a slight run of water can be produced over the top, the water percolating through the crevices of the stone roof will fall from the latter in large drops on a large stone forming the bottom of the cave or recess, and will be thrown on the stones or rock for some height and distance. This will be sufficient in most cases to afford a constant supply of moisture by the evaporation continually going on, and is far superior to any syringings; but when it cannot be adopted every surface must be sprinkled twice daily. The finest-rosed syringe only should be employed. If the house is sufficiently humid, every morning the fronds will be covered with minute dew-like drops of water, and if it is not so moist as this the plants will soon become brown, and the young fronds perish. It is useless attempting the growth of Filmy Ferns in an ordinary fernery unless suitable places are provided for them, for, as before remarked, it is seldom sufficiently moist, or if it is, it will be too much so for some kinds of Ferns, especially in winter when their fronds are mature. For this reason Filmy Ferns are generally grown under glass shades, where, however well cared for, they seldom remain long healthy, which is mainly to be attributed to the closeness of the atmosphere.

The pans in which the plants are grown cannot be too well drained, and should be filled with the compost already mentioned, the plants being placed in the centre, and the surface of the soil covered with pieces of sandstone, but not entirely. The shades should rest upon fine pieces of grit, and any water that may be necessary for moistening the roots should be poured upon the glass, and should pass clear away, and not be retained about the roots by having the pans in saucers filled with water. To maintain the requisite degree of humidity the shades should be removed, and the plants sprinkled overhead once or twice a-day, or once or twice a-week, as may be necessary, in order to have the shades covered with moisture every morning, and the fronds studded with minute drops of dew from the condensation during the night. To keep the plants healthy there should be one hole at the top of the glass for the admission of fresh air, or the escape of that which is vitiated, and two or three holes when the shades are large. Different species of course vary in respect to the treatment they should receive, but all require air, constant humidity, and a free, moist, sweet soil. With stagnant water in the soil and an excessively humid and close atmosphere, they will not thrive; in fact, some kinds require so much fresh air that they soon become unhealthy under glass shades. The shades should be taken off occasionally and wiped dry, and if this is done every morning all the better, replacing them before the fronds become dry. So important, indeed, is fresh air to this class of Ferns, that it is preferable to grow them in Wardian cases with moveable lights, placed in houses having the requisite temperature and shade. In cases, the plants can be well provided with every essential to their growth; those which grow on wood can be placed on logs laid in a suitable position, all can be readily syringed, any amount of water may be given, and they can be seen at any time. In any ordinary fernery the lights of the case may be half, or fully open, as the sides will prevent an undue amount of moisture being dissipated, and an excess of it may be dispelled by raising the lights, whilst that which is necessary can be secured by shutting them partially, or completely. At night the lights should be fully or nearly closed to promote condensation and the deposition of dew on the fronds, and if the moisture is not excessive it will not do more than hang in the finest possible drops on the fronds of the beautiful and delicate-textured Filmy Fern.—G. Abbey.

CUTTING BOX EDGINGS.

As the season for cutting the edgings of walks has now arrived, I write to recommend the grass-edging shears for cutting Box edging. I have used them for many years, and I find them

greatly superior, by reducing the time required to do the work, and easing the workman, to the hedge shears or scythe, both of which I have ceased to use for the purpose. In large gardens where there is much of this work to do, grass-edging shears will be found very useful. The work can be done without using the line, or topping, and if the edging be cut every year, this may be done very speedily. I believe this tool has been used by others, but not so much as is desirable, for cutting Box edgings.—James Reid.

CULTURE OF TRICOLOR PELARGONIUMS—TURF SOIL FOR POTTED PLANTS.

In your number of April 18th, Mr. Wills recommends fresh turfy loam and bone dust, and manure water when the pots are well filled with roots. I know the plants will grow amazingly in this compost, and the young leaves are very nicely coloured, but as they develope themselves the colours lose their brightness and regularity, and the leaves become very large and soft, and lose that fresh appearance which I consider so essential in this section of Pelargoniums.

I practised that method of growing them three years ago, and strongly recommend it when the object is to increase the stock quickly; but I now, in growing specimens for the decoration of the conservatory, dispense with the fresh loam and manure water, and use the loam with the fibre in it quite half-decayed to feed the plants instead. I find them make sturdier and shorter-jointed growth, smaller leaves, which retain their freshness of colouring a greater length of time, and the plants exhibit altogether a much smarter appearance than when grown soft and luxuriantly. I do not think boiled half-inch bones have this objectionable effect, and though I have not recommended them in my book on the hybridisation* of this class of Pelargoniums, I believe such may be used with advantage; but I cannot perceive what use a 32-sized-potful of the bones in a barrow-load of compost can be. I have used three times that quantity, but I consider it very extravagant, unless the plants had to remain in the same soil for a long period.

I do not understand what Mr. Wills means by a temperature of 55° or 60° for the atmosphere, and of 45° or 50° for bottom heat in the propagating-house; the small thumb-pots, which are about 1¼ inch deep, to be partially plunged. This would suggest the idea that an inch of the material on the surface of the bed should be 10° lower than the atmosphere in the same house. If there is any misprint here I think it would be as well to draw attention to it, as I have known amateurs very much perplexed by trifles of this sort, in trying to adhere strictly to instructions laid down for them.

The cuttings strike very freely in a temperature of from 55° to 60° in my propagating-house, on the platform, which has three hot-water pipes (four-inch), underneath it, all on the same level, about 6 inches lower than the under surface of the platform, which is 7 feet wide; the flow-pipe runs down the middle. There is a T-pipe at the extreme end from the boiler, then an elbow on each side, and a return-pipe runs down each side of the flow the full length of the platform, which is formed of slate, supported by brick pillars 4 feet apart.

I find Pelargoniums and all softwooded plants strike freely on this platform, either in or out of pots. There are no other pipes for heating the atmosphere. The platform is 4 inches from the front wall to allow the heat to come up; of course there is nothing to prevent its rising at the back where the path runs.

Much having been written of late respecting the use of fresh turfy loam for general purposes, I beg to state the results of my experience for the benefit of amateurs who, I know, look so anxiously after information of this sort. As a rule, I use fresh turf for Vines, or anything that has to remain a long time in the same soil or pot, as Camellias; but for anything that is required to develope itself quickly, and do the whole of its work in the period of two or three months after the last shift, and is then shaken out of the pots, as are Pelargoniums and most softwooded plants, I prefer having the turf quite half decayed. Also, for Cucumbers, I prefer it thus decayed, as it is ready for them to feed upon at once, and they make stouter and shorter-jointed growth.

I am afraid that those who use loamy turf for Azaleas will find themselves in a bad way in two or three years, just when their plants should be at their best. I have used it, and am thoroughly acquainted with its effects.

As regards making moderately-large heaps of turf—say 3 feet wide, and 4 or 5 feet high, to decay for potting purposes, I can see no objection to the practice. I once made a very large heap of turf that was taken from a field that was to be ploughed, which had never been broken up before "in the memory of the oldest inhabitant." The third spring from the time that it was stacked I found it suit my purpose better than it had done before. In fact, I never had plants succeed so uniformly. I am quite decided it was more valuable in that state than when fresh, consequently I recommend such turf in all cases where the plants are required to do their work in a short period of time. I know a specimen plant-grower, probably the best in England, who stacks his turf in very large heaps.—T. Dixon, *Gardener, Waterdale, Sutton, St. Helens.*

* Mr. Dixon calls it hybridisation, but, strictly speaking, it is cross-breeding.

ROYAL BOTANIC SOCIETY'S SPRING SHOW.

This, the last spring Show for the season, was held on Saturday and though the showers in the forenoon were frequent and heavy, the afternoon was tolerably fine, and there was even some sunshine.

Roses again constituted a leading feature, and among those shown by Messrs. Turner, Paul & Son, and Lane, were specimens which for beauty and profusion of bloom it would be difficult to surpass at any season. For nine, Mr. Turner was first with Charles Lawson, very fine, a magnificent specimen of Victor Verdier, and Alpaide de Rotalier, Lord Clyde, Maréchal Vaillant, Professor Koch, Celine Forestier, with thirty blooms, Madame Villermoz, and Souvenir d'un Ami, all of which were excellent. Messrs. Paul & Son, who were second, had of rose-coloured kinds, beautiful specimens of Anna Alexieff, and Madame de Stella; Lord Clyde, and Madame Boutin, crimson; Le Rhone, deep red; and of Tea varieties, Alba Rosa, Souvenir d'Elise, President, and Souvenir d'un Ami. Messrs. Lane & Son were third with very good specimens of Vicomte Vigier, Pierre Notting, with numerous rich velvety dark crimson blooms; Jean Goujon, rich violet-shaded crimson; Anna Alexieff, Comtesse de Cabrillant, and Triomphe de Morny, different shades of rose; Louise Darzens and Madame Alfred de Rougemont, white. Messrs. Lane also exhibited a small collection, for which they were awarded an extra prize.

In the Amateurs' Class good specimens of François Lacharme, Madame C. Wood, Jules Margottin, and others from Mr. James, gardener to W. F. Watson, Esq., Isleworth, and Mr. Wiggins, gardener to W. Beck, Esq., took the first and second prizes.

For new Roses of 1864, 1865, and 1866, Messrs. Paul & Son were first with Fisher Holmes, velvety crimson; Princess Mary of Cambridge, pale rose; and Duchesse de Caylus, bright carmine. Mr. Turner was second with Duchesse de Caylus, Maréchal Niel, very fine, and Mademoiselle Marguerite Dombrain, delicate rose colour. Messrs. Lane, who were third, had Dr. Andry, cherry red; Marcella, salmon rose, shading off to white; and Duke of Wellington, shaded velvety crimson.

Several boxes of cut blooms were shown, in which were fine examples of Maréchal Niel, John Hopper, Exposition de Brie, Camille Bernardine, Mdlle. Marie Rady, Madame C. Wood, Celine Forestier, and Vicomte Vigier; but the gem of the whole was Maria Baumann, bright red, shown by Mr. Turner. Messrs. Paul & Son had a first prize for twenty-four blooms, Mr. Turner being second, and were also first for miscellaneous boxes.

Of Pelargoniums Mr. Wiggins was the only exhibitor, taking the first prize with, for this season, finely-bloomed specimens of Vestal, Beadsman, Roseum, Pline, and Madame Reicie.

Mr. James had extra prizes for Calceolarias, of a very good strain, and Cinerarias; and a similar award was made to Messrs. Dobson and Son for nine Azaleas, among which were Reine des Doubles, bright rose, and Baron de Vrière, blush, heavily spotted with rosy crimson in the upper petals.

Of Auriculas, the best were those shown by Mr. Turner, of Slough, who had Lycurgus (Smith), Duke of Kent (Dickson), General Bolivar (Smith), Sophia (Chapman), Fair Maid (Lightbody), and Metropolitan (Spalding). Messrs. Dobson & Son were second in the nurserymen's class, and in that for amateurs Mr. Butcher, of Camberwell, was first with Sophia (Chapman), John Penn, Robert Traill (Lightbody), Blucher, and Bright Phœbus; Mr. Cox, Camden Town, and Mr. James being second and third. Mr. Turner also exhibited several seedlings, of which Crown Prince, mulberry self, Cheerfulness, Colonel Champneys, and Charles Turner received first-class certificates; likewise a fine collection of Alpines. Of these Lustre, rich reddish brown, had a first-class certificate, whilst Defiance, Jessie, Trumpeter, Selina, and Vivid were awarded certificates of the second class.

Of Pansies, the best twenty-four cut blooms came from Mr. James, Mr. Hooper, Bath, being second; and the first-named exhibitor also took an extra prize for excellent plants in pots, the varieties being Masterpiece, Dux, Imperial Prince, and Rev. H. Dombrain, dark selfs; Vesta, primrose self; Wm. Austin, J. B. Downie, Chancellor, and A. Wharrard, yellow grounds; and Cupid, Miss E. Cochrane, and Lady

E. Stanley, white grounds. Messrs. Downie, Laird, & Laing, also exhibited blooms of Imperial Blue, purplish blue, with a yellow eye and a dark blotch on the lower petal. This variety, which has been exhibited on several previous occasions and taken certificates, promises to be useful for bedding.

Collections of fine-foliaged and flowering plants from Mr. Williams, Holloway, Mr. Wheeler, gardener to Sir F. Goldsmid, Bart., and Mr. Burley, Bayswater, received prizes in the order named, and comprised Croton variegatum, Yucca aloifolia variegata, and Cordyline indivisa, all of which were fine specimens; Imantophyllum miniatum with eight heads of bloom, Eriostemon pulchellum, Azaleas, the pretty rosy-flowered Adenandra fragrans, Alocasia metallica, variegated Pandanus javanicus, Palms, and Dracænas. Mr. Williams also had an extra prize for a miscellaneous collection, in which were the beautifully-striped Yucca quadricolor, good specimens of Agave filifera, Dasylirion acrotrichum, Todea superba, Palms, Orchids, the scarlet-spathed Anthurium Scherzerianum, and some other plants.

Of new and rare plants Mr. Bull furnished a rather numerous collection, comprising Rogeria gratissima, Chamærops melanocantha in flower, Saurauja sarapigiensis with bold reddish bronze-like foliage, Bertolonia margaritacea, Dieffenbachia Weirii with dark green foliage mottled with yellowish green, Athyrium proliferum, an elegant stove Fern from Ceylon; also the following, which received first-class certificates—viz., Coprosma Baueriana variegata, a New Zealand plant, with obovate leaves broadly edged with yellow; Dioscorea discolor variegata, with leaves richly mottled with brown and green; Anæctochilus Dayi, dark green, veined with red; A. petola marmorea, deep brownish green, with beautiful pale green, almost silvery markings; Terminalia elegans, with dark-veined pale green trifoliate leaves, having narrow leaflets with red midribs; and Adiantum Lindeni, a handsome robust-looking stove Fern. Second-class certificates were given for Athyrium costale dissectum, a pretty East Indian Fern, and Azalea Queen of Roses with large rosy crimson flowers. The latter being also shown by Mr. Williams under the name of Reine des Roses, a similar award was made to him. To Mr. Williams first-class certificates were awarded for Stenochlæna heteromorpha and Amaryllis aurantiacum, the latter having showy orange red flowers, with a greenish white centre; and apparently the same variety in a smaller state came from Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton. Mr. Wilcock, gardener to Dr. Pattison, St. John's Wood, exhibited a Dendrobium called Farmeri aureum-flavum, but resembling D. chrysotoxum, the little white-flowered D. Heyneanum, and the showy orange-flowered D. Cambridgeanum. Lastly, Mr. Burley exhibited a plant belonging to that curious genus Xylophylla, in which the flowers are borne on the margins of the flattened leaf-like branches, as in the specimen shown.

Among miscellaneous subjects extra prizes were awarded to Mr. James for a collection of British Ferns, and to Mr. Bull for two plants of Agave filifera, each globular and about 18 inches in diameter, and the two so nearly alike that it would be almost impossible to distinguish one from the other. An extra prize was also awarded to Mr. Gardiner, gardener to Sir G. Phillips, Bart., Shipston-on-Stour, for a good dish of Peaches for the season. Mr. Wiggins contributed some fine Polyanthuses, Mr. Ward, gardener to F. G. Wilkins, Esq., Cattleya citrina with five of its showy yellow flowers, and Messrs. Ivery a basketful of Azalea Fascination, a beautiful variety with rose-coloured flowers broadly edged with white, and richly spotted in the upper segments.

ROYAL HORTICULTURAL SOCIETY.

Dr. Masters devoted his concluding lecture on Saturday last, to the consideration of the Flower. After pointing out the various parts and remarking that some are useful for protection and others for attracting insects, he said that the numerous forms which the flower assumes may partly be explained on the same principles as those on which the leaves are arranged. If the parts of the flower are few and even in number, they are usually arranged in pairs crossing each other; but if they are many, or the number is odd, 3 or 5, the arrangement is spiral. Thus, as a rule, the organs are so placed as not to interfere with each other, and where this rule is departed from there is either a great disproportion in the size of the organs, or their direction is different.

After touching on the causes which lead to deviations from what may be taken as a standard of a perfect flower, in which all the parts are present, and which were explained by the union or suppression of parts, the disproportionate growth of some parts of the flower as contrasted with that of others, was referred to as a frequent cause of variation in the shape of flowers. With reference to double flowers their peculiarities were stated to be principally due to the substitution of petals for stamens and pistils, and to the multiplication of the numbers of parts. Thus, the lecturer remarked, while the general plan of construction in flowers is simple and uniform, great divergences in matters of detail are provided for with a view to the well-being of the individual plant, or of the community to which it belongs.

PRICE OF STRAWBERRIES.

I was surprised on referring to your list of prices of vegetables and fruit of April 24th, to see Strawberries quoted at 6*d.* to 1*s.* per oz., when it is a well-known fact that they have been selling at 5*s.* per oz. for some time.—A Constant Subscriber.

[Our quotations are correct, and have been since Strawberries came in; the retailers are buying them at 6*s.* to 10*s.* per lb., and selling them at 8*s.* to 16*s.* per lb., and will supply "A Constant Subscriber" with any quantity at those prices. We are sorry that country purchasers have been so victimised. —Eds.]

PARIS UNIVERSAL EXHIBITION.

We have not been unmindful of those portions of this Exhibition which are entitled to a notice in these pages, and we shall give of them a full report. At present we shall do no more than detail the awards of prizes to the second series of exhibitors from April 15th to April 30th. The third series commenced on the 1st inst.

GENERAL EXHIBITION OF CONIFERS.

Ornamental Conifers in pots, baskets, or planted out before March 31st

1. Collection of species and varieties.
   First prize, M. Deseine, Bougival. Second, MM. Defresne et fils, Vitry. Third, M. Oudin, Lisieux. Honourable mention, MM. Paillet fils, Chatenay; Croux et fils, Sceaux; Moreau, Fontenay.
2. Fifty out-door species and varieties.
   First prize, Messrs. Veitch & Sons, London. Second, M. Morlet, Avon, near Fontainebleau. Third, MM. Jamin et Durand, Bourg-la-Reine. Honourable mention, M. Rémont, Versailles.
3. Twelve distinct species remarkable for their selection and growth.
   Second prize, M. Charozé, à la Pyramide, Angers. Third, M. Alfroy neveu, Lieusaint (Seine-et-Marne). Honourable mention, M. Cochois.
4. Six specimens, different kinds, for the decoration of gardens.
   First prize, M. Cochet, Suisne. Second, M. Rémont, Versailles. Honourable mention, M. Alfroy-Duguet, Lieusaint (Seine-et-Marne).
5. The best single specimen.
   First prize, M. Cocher, for a Thuja gigantea. Second, Krelage et fils, Haarlem, for a Picea Nordmanniana. Third, M. Oudin, for a Picea pinsapo. Honourable mention, M. Alfroy neveu, for a Pinus Sabiniana.
6. Twenty-five different kinds of Abies remarkable for their growth and selection.
   Third prize, M. Paillet fils.
7. Recently introduced species.
   First prize, M. Adrien Sénéclauze, Bourg-Argental (Loire). Second, Messrs. Veitch & Sons. Third, MM Thibaut et Keteleer, Paris. Honourable mention, MM. Paillet fils, Paris; Oudin, Lisieux.
8. Collection of New Hardy Conifers not yet sent out.
   First prize, Messrs. Veitch & Sons. Third, M. Oudin. Honourable mention, M Adrien Sénéclauze.
9. Araucarias remarkable for their size.
   Third prize, M. Daudin, Pouilly, (Oise). Honourable mention, M Knight, Château de Pontchartrain (Seine-et-Oise).
10. Collection of Araucaria imbricata.
    Second prize, M. Oudin.

In what are termed the accessory classes the following awards were made:—

HOTHOUSE PLANTS.

1. Collection of twenty different plants in or out of flower.
   First prize, M. Chantin, Montrouge.
2. Collection of twelve plants remarkable for size and good cultivation.
   Third prize, M. Lassus, Paris.
3. Collection of six plants remarkable for size and good cultivation.
   First prize, M. A. Verschaffelt. Ghent.

CACTI.

1. Collection of species and varieties.
   First prize, M. Cels, Chaussée du Maine, Paris. Second, M. Pfersdorff, Avenue de Saint-Ouen, Paris. Third, M. Ramus.
2. Collection of twenty-five species.
   First prize, M. Pfersdorff.
3. Collection of twelve species.
   First prize, M. Ramus.
4. Species and varieties grafted.
   First prize, M. Pfersdorff.
5. Collection of twenty-five species or varieties, grafted or not, in flower.
   Third prize, M. Pfersdorff.
6. Species and varieties of Cereus.
   First prize, M. Cels.

SELAGINELLAS.

New species or varieties.
Second prize, Messrs. Veitch & Sons. Third, M. J. A. Willink, Amsterdam.

GREENHOUSE PLANTS.

Collection of species and varieties of Agave.
First prize, M. Cels. Second, M. Chantin.

Collection of select species of Agave.
First prize, M. J. Verschaffelt, Ghent.

Collection of Aloes.
Second prize, M. Pfersdorff.

Collections of Bonapartea, Dasylirion, and Littea.
First prize, M. J. Verschaffelt.

Collection of Greenhouse Yuccas.
Second prize, MM. Jamin et Durand.

Collections of Himalayan and Japanese Rhododendrons in flower.
Third prize, M. Knight.

Cinerarias in flower.
Second, prize, M. L'Huillier. Third, M. Bonatre, Neuilly.

Hyacinths, species and varieties in pots.
First prize, MM. Krelage et fils. Second, The Prussian Government. Third, M. Thibaut-Prudent, Paris. Honourable Mention, MM. Havart & Co., Paris.

Twenty-five varieties in pots.
First prize, MM. Krelage et fils.

Collections of Pansies.
Second prize, M. Falaise, aîné, Boulogne (Seine). Honourable Mention, M. Falaise (Edmond), Rue de Billancourt, Paris.

Collections of Roses.
First, M. Jamain (Hippolyte), Paris. Second, M. Margottin, Bourg-la-Reine.

New Plants.—Collection of seedlings.
Honourable Mention, M. Cocher, for Beschorneria multiflora.

Collections of Forced Vegetables.
First prize, Horticultural Society of Clermont (Oise).

Asparagus.
First prize, M. Louis Lhérault, Argenteuil.

Collection of Trained Fruit Trees.
First prize, M. Cochet, Suisne, for Palmette training. First, MM. Jamin et Durand, Bourg-la-Reine, for Pyramids. Second, MM. Croux et fils, Sceaux. Third, M. Deseine, Bongival. Honourable Mention, M. Defresne and M. Gilekains (Belgium).

Trained Peach trees.
First prize, M. Chevalier, Montreuil. Honourable Mention, M. Gilekains.

Cherry, Apricot, and Plum trees trained in different ways.
Honourable mention, M. Croux.

Four Apricot trees trained for walls and espaliers.
Third prize, MM. Jamin et Durand.

Four Plum trees trained for walls and espaliers.
Honourable mention, MM. Jamin et Durand.

Vines.
Honourable mention, M. Rose Charmeux, Thomery.

ASSISTANTS.
First prize, M. Forest, for the training of the trees exhibited by M. Cochet.

INSIDE VINE BORDERS.

There has been some pleasant controversy in your columns about Vine borders, some of your correspondents advocating inside borders, and some the converse. I am not a grand Grape-grower, showing for prizes, but I delight in Vine culture in my small cottage way, not caring for large bunches, but having a great relish for Grapes of fine flavour.

I have what is called a vineyard under glass, which to me is a great source of delight. It is a small span-roofed house, 20 feet long, and 14 feet wide; there is a path in the centre, and a border on each side. In each border I have fifteen Vines, trained to upright rods and spurred in. This is the third year of their growth, and nearly every Vine is showing abundance of fruit, three or four times more than they must be allowed to ripen.

I happened to be in my house on this sunny day (April 29th)—a rare thing this spring, and on observing the vigorous shoots my Vines are making, with their roots in my inside borders, and the comparatively backward state of some Vines with their roots in a border outside, sloping to the south-west, in a dry sandy soil, I was induced to sink two thermometers in the borders about 8 inches in depth. I allowed them to remain there, well covered with earth, to an exact level with the surface of each border, from 11 A.M. to 2 P.M. On taking them out I found that which had been buried in the inside border standing at 62°, and that from the border outside, only 18 feet from the inside border, standing at 51°, giving a temperature 11° below that of my inside border. Please to tell me if I am right in considering a warm border better than a cold one for the roots for Vines.—A Young Vine-grower.

SORGHUM TARTARICUM.

It is with much regret I note in your Journal of April 25th the remarks respecting this new cereal; for, relying on Messrs. Carter & Co.'s advertisement, I have not only planted a quantity of it myself, but many friends, to whom I recommended it, have also been to the same expense and trouble; and now our seed is but scarcely in the ground, when you inform us that it is an old failure under a different name, and that it will never be of any service in this country. That Messrs. Carter must have been deceived is very evident, and it is fortunate they are so well known as an honourable and respectable firm, but if the statement in your Journal is correct, some explanation is surely due from them concerning it.—W. P., *Cadbury*.

ORCHARD-HOUSE MANAGEMENT—WATERING.

AN EXAMPLE FOR AMATEUR GARDENERS.

I take a great interest in my orchard-house. It is a span-roof built of wood and glass after Mr. Rivers's plan, and I have put a four-inch pipe round it; it is 42 feet long by 14 wide. I am in a peculiarly cold and backward climate, and wish to push the trees a little. My present system is to keep the ventilators at the two ends of the roof open day and night. I open all the side ventilators at eight o'clock, unless the wind is rough or cold, when I keep the shutters closed, or nearly so, on the side towards the wind. I keep the pipes warm day and night, and shut up the house, except the two top ventilators, at three o'clock, when I syringe. At present the trees look as well as they possibly can, and the fruit is set beautifully. My doubt is whether I do not waste heat by giving so much air. I wish for information how to manage the house from this time till the fruit is ripe, so that I may have the crop as forward as is safe.

I often hear persons, especially gardeners, rail at orchard-houses, and I observe one great point with them all is the trouble of watering, supposing the trees to be in pots as mine are. I think this objection has not been met in your pages with the very sufficient answer "that such trouble as that of watering the tree is not skilled labour." My "head man" is not sixteen years old, and he is perfectly competent to water the trees—the pruning, &c., being a pleasure to myself. I think it worth while, then, to try to prevent persons from being discouraged by gardeners who, very probably, can make a Peach-house with trellis answer better than an orchard-house; but with a large proportion of amateur gardeners there is the skill and willingness to do the light and easy work of the orchard-house, while the heavier work may be done by a boy; the regular reach house, on the other hand, requires the eye and hand of a trained gardener.

I have but little time for gardening myself; but I have five houses heated—all, of course, small; and with the occasional help of a labourer, say three days a-week, from April 1st to September 30th, and my superintendence, my sixteen-year-old man manages the whole, and about two acres of garden and lawn. My houses, sheds, soil, water-tank, &c., are placed close together. My walks are edged with tiles, so that salt keeps them clean. My lawn is mown with a machine, and my wall trees and pot trees I prune and nail myself; and I believe my garden bears comparison with many where the expense in labour is threefold.—C. P.

[High praise is your due for keeping your garden and houses with such a small amount of labour, but as you do so much yourself *con amore*, your case could hardly be cited as applicable to those places where little is done either with the eye or the hands of the proprietor, except to make work instead of lessen work for others to do.

Even though the watering of orchard-house trees in pots can be done by unskilled labour, yet that labour, and especially if water is scarce and has to be brought in pails or barrows from a distance, becomes a serious item, and more especially when houses, water, &c., are not placed so near together as yours are. A proprietor, and an amateur who is one, can arrange these things to suit best and thus save labour; but many gardeners find it difficult to get a shilling spent in these directions, even

though the spending of the shilling would, ere long, save pounds. We could name many places where in the way of watering alone labour would be greatly lessened by the expense of pipes for carrying the water where it is most needed. In fact, our experience would say, If you wish to see improvements go to an enthusiastic amateur. He will not scruple to lay out a little money which will insure a constant saving afterwards. With all these allowances, however, we consider that your management, with the head man of sixteen years old, and an occasional labourer, is highly meritorious. Gardeners as a body are well aware of the interest and variety to be obtained in orchard houses.

Your house, however, is hardly an orchard-house, further than its first cheap erection, as your hot-water pipes give you all the advantages of a Peach-house or a vinery. We quite agree with you, that, having that piping, you should bring in the fruit earlier, and this you can do by having less air, but taking care that the house do not become too hot by sun heat. As the season advances you will want all the air at midday in bright weather, but you can do much by giving only a little in the morning, and shutting up early. Mr. Rivers regulates his side ventilation by having gauze or thick netting inside of the ventilators. By two tacks and a looped string we can open ours a couple of inches or less, onwards to a full opening, and provided a little air is given early, that will do for moderate days, and more must be added if the sun is powerful. Provided air is given early, the house may range with sun heat from 70° to 90°, but rather below 90° than above it. From 50° to 60° at night. See Doings of Last Week.]

PEACHES AND NECTARINES IN AN ORCHARD HOUSE.

I HAVE a small lean-to house, 16 feet long by 9 feet wide, which has a south aspect, and is heated by a flue from another house, running through it about 12 inches from the back wall. There is room for an inside border, about 5 or 6 feet wide. The roof is a little flatter than 45°. Would this be a good place for a Peach tree trained up the glass? The house could be emptied in a month's time, and as I have two trees (a Peach and Nectarine), very suitable in size, and about four years old, I should be glad to know if they could be moved into the house when the border is completed—say in six weeks' time. They are now planted against a low wall, but in an unfavourable situation for ripening their wood properly. Being anxious to have a little fruit next year, I should like to know in the first place if the house would be really suitable for growing those fruits; and, in the second place, if moving the trees in full leaf would be better than leaving them as they are till October, and then bringing them into the house with plenty of soil.—A. R. L.

[The Peach and Nectarine trees will do admirably in the border inside the house; but you must not think of moving them in six weeks. Let them alone until towards the end of September or the beginning of October. By moving early and carefully in autumn you will be sure of a crop in the following year. You may grow something else in the border in summer, as Cucumbers or Melons.]

A WORTHY EXAMPLE.

I AM a small freeholder residing about a mile south of Christchurch, near Canterbury, in New Zealand, and until about two years and a half ago was totally unacquainted with gardening either as to its science or practice; but being driven by stern necessity, I arrived at the conclusion that nothing short of two very important branches of horticulture would be likely to set me right, and these were the culture of the Cucumber and that of the Grape.

How was I to surmount my difficulties? I was not only out of work, but was greatly in debt, and yet both of these productions required glass structures.

Neither in theory nor practice did I know anything of the culture of either; but, nndespairing, by one honest means and another I obtained both wood and waste glass, that enabled me to construct a house such as I most fancied, and from which ultimately through hard struggling and perseverance I was enabled to obtain a fair crop of Cucumbers in the first season. By the aid of Mr. W. Thomson's "Treatise on the Grape Vine" I likewise obtained, in the same season, good growths from my young Vines, which enabled me, in the February of the following year (1866), to carry off the palm at our Christchurch horticultural show with beautiful bunches of Black Hamburgh Grapes, each weighing upwards of 1¾ lbs., from my year-old Vines.

I likewise constructed 74 feet run of Cucumber-frames, walls of mud or cob, which I took great pains with, and I finally succeeded in obtaining both glass and wood, as well as stable-manure for hotbeds. I am happy to inform you that last season I cut not less than 2600 Cucumbers, which I sold for no less than £99; and that again enabled me last winter to construct a large vinery 40 feet long by 28 feet wide, and with a span roof, and six-feet walls of glass all round. This I intend to be a vineyard under glass; and I have filled all under it with as good a three-foot border as I could, to about 3 feet all round the outside. To this I shall add, as the Vines advance. The house itself rests on charred, stout wooden piles, resting on the firm ground beneath. The Vines I think of training horizontally on trellises in the body of the house, leaving the roof clear; they are chiefly Black Hamburgh, but I think there is heat enough for a Muscat.

I have planted 180 young Vines struck from eyes this spring, and I think I have no cause to grumble, though they are not making that headway which I had expected, but it was late in the season when I had the house ready for them, and Christmas had arrived before I had them planted; but more of this some other time.

I wish now to ask you to inform me why some of my most prolific Cucumbers prove bitter oftener than others—in fact, they are the only ones which prove bitter. Do you think it arises from the plants, the mode of training, or the lack of saline matters in the manure? I have hitherto trained my Cucumber vines on the soil, inside the frames, pegging down the branches where they have rooted, and I imagine this has greatly assisted the plants. Last year I followed the same practice, and cut Cucumbers from the same vines for six months, from the 1st of December to June, and all through the season I never heard of more than six or eight bitter fruit. This season the seeds which I was most anxious to obtain not having arrived from England, I was obliged to do the best I could with what seeds I could procure, and the result was some proved very prolific, but with a great tendency to be bitter. The sun being very powerful here during the middle of the day, with strong north-west parching winds, I have often made it a practice to shade with canvas, and shut up closely during the heat of the day, and the thermometer in the frames has often risen to 100° during such times. I have likewise often watered the beds with liquid manure, but sprinkling the foliage with clean water. I always use water of the same temperature as that of the frames.—THOMAS LORD.

[Our correspondent is a member of Nature's peerage—a true "lord"—one of those who are the conquerors, not the slaves of circumstances. We hope often, and for many years, to receive the reports of his well-doing. We have done all that he asked us to do in a postscript not needing publication, and we now answer his query. Bitterness is always present in the stalk-end of the Cucumber, being the part least ripened. When it first occurred in our own practice we concluded that the sap supplied to the fruit was not sufficiently elaborated, so we increased the temperature of the bed, allowed a freer exposure to the light, and admitted air more liberally, both during the night and the day. We had no more bitter Cucumbers.]

NEW BOOKS.

A Handy Book of Meteorology. By ALEXANDER BUCHAN, M.A., &c. W. Blackwood & Sons, Edinburgh and London.

WHEN we opened this pocket volume the first sentence we read was—"The truth is, no prediction of the weather can be made, at least in the British Islands, for more than three, or perhaps only two, days beforehand; and any attempt at a longer prediction is illusory," and we promptly concluded that it is an honest book. Little did we think, however, that we should thoroughly read its pages, but we did, and have placed it in the row of authorities on our table, ready for reference; for it is, most truly, what it is designated, "A Handy Book." It is one of those books, too few in number, which contain nothing but what is desirable to be in its pages, and all is told clearly and pleasantly, as no one can narrate except a writer who is thoroughly master of his subject. We have not often

the pleasure of speaking thus of a publication, and every reader of the volume will assent to our opinion of its merits.

We recommend it especially to our gardening friends, not as a foreteller of weather, but as an explainer of many of their operations, and as a guide to much information which they are continually needing. Thus, there are isothermal maps, showing at a glance the temperatures of the air and soil to which a plant is accustomed of which they know the native place. Every chapter, however, contains explanations and facts, enabling the gardener thoroughly to comprehend the reasons for many operations which he has been taught to adopt, and so to comprehend them constitutes enlightened practice. We have many passages marked which deserve extract, but we must be content with the following:—

"*Radiation from the Earth.*—The degree to which the temperature falls depends on the radiating and conducting powers of the surface over which the thermometer is placed, being greater as the radiating power is greater, and the conducting power less, and *vice versa*.

"One of the most instructive examples illustrative of this subject that could be given, is the result of Mr. Glaisher's observations on the different temperatures of long and short grass. A thermometer placed on long grass was found to be on a mean 1.1° lower than one on short grass, whilst the temperature of the soil under long grass was 1.1° higher than under short grass. The temperature was thus the same amount in excess under the long grass, as it was in defect over it. Hence the difference of temperature over the long and the short grass was entirely due to the greater quantity of heat conducted from the soil to the top of the short grass, over that conducted to the top of the long grass, and not to any difference in the radiating powers of the grasses. The experiments were extended, and it was found that the temperature varied with every variation of length, fineness, and closeness of texture of the blades of the grass."

"*Dew-point.*—The ascertaining of the dew-point is of great practical importance, particularly to horticulturists, since it shows the point near which the descent of the temperature of the air will be arrested during the night. For when the air has been cooled down by radiation to this point, dew is deposited, and latent heat given out. The amount of heat thus set free being great, the temperature of the air is immediately raised. But as the cooling by radiation proceeds, the air again falls to, or slightly under, the dew-point; dew is now again deposited, heat liberated, and the temperature raised. The same process continues to be repeated, and thus the temperature of the air in contact with plants and other radiating surfaces may be considered as gently oscillating about the dew-point. For if it rises higher, the loss of heat by radiation speedily lowers it, and if it falls lower by ever so little, the liberation of heat as the vapour is condensed into dew as speedily raises it. Thus, then, the dew-point determines the minimum temperature of the night.

"This suggests an important practical use of the hygrometer. If the dew-point is ascertained by it, the approach of low temperatures or of frost may be foreseen and provided against. Thus, suppose on a fine clear spring day, towards evening, that the dry bulb was 50°, and the wet 40°; the dew-point at the time is, therefore, 29.4°. Frost on the ground may then be predicted with certainty, and no time ought to be lost in protecting such tender plants as may be exposed in the open air at that season. If, on the other hand, with a sky quite as clear, the dry bulb was 50°, and the wet 47°; the dew-point being thus 43.8°, no frost need be apprehended. The raising or depressing of the dew point during the night by a change of wind, is the only circumstance that can happen to interfere with the predictions founded on the hygrometer."

A Practical Treatise on the Hybridisation and Cultivation of the Tricolor Pelargoniums. By Thomas Dixon, Gardener to W. Blinkhorn, Esq., Waterdale, Sutton, St. Helens.

The title-page tells the truth—this *is* a trustworthy, practical treatise, and we recommend every one who desires to raise new varieties of these Pelargoniums, to send thirteen postage stamps to Mr. Dixon, for a copy. We say "every one," because the directions are so full, and so explicit, that the most inexperienced will readily understand how to proceed. There are ample instructions arranged under the following heads:—

"1st, To secure the most suitable varieties for parent plants.

"2nd, That they should not be in an exhausted state for want of rest.

"3rd, That the plants should not be grown too luxuriantly by applying stimulating manures.

"4th, That the atmosphere of the house be dryish when the anthers open, so that the pollen will not be caked together, and unfit to apply to the stigma.

"5th, That the seeds be kept neither too wet nor too dry in the seed-pan.

"6th, That the young seedlings get strong before potting from the seed-pan.

"7th, That they do not damp off from being over-watered, kept too close, or for want of heat, after they are potted from the seed-pan.

"8th, That the plants for hybridising be put under growing treatment not later than the latter end of February, or the beginning of March, better sooner than later; in fact, any time after the middle of January."

NOTES AND GLEANINGS.

Her Majesty has signified her intention of laying the first stone of the Hall of Arts and Sciences on Monday, the 20th of May. The contractors for the building, Messrs. Lucas Brothers, are busily engaged in making preparations for the ceremony. The ground is being excavated some feet in depth, so as to mark out the amphitheatrical form of the building, and the excavation will be covered in with canvas to protect the spectators of the ceremony from every contingency of weather.

—— It is our painful duty to announce the death of the Rev. George Cheere, of Papworth Hall, St. Ives, Huntingdonshire, which took place on the 10th of April. The deceased gentleman was a member of the Floral Committee of the Royal Horticultural Society, as well as one of the Vice-Presidents of the International Horticultural Exhibition, and took a great interest in horticulture, being himself an occasional exhibitor. We last saw him, then apparently in full health and vigour, at the Floral Committee meeting on the 6th of March, where he had six pots of Mignonette, which were the admiration of every one; and on several other occasions he exhibited remarkably fine Anne Boleyn Pinks.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus, in cutting, all the first shoots should be taken. If one or two of the strongest stems are allowed to run up, the other shoots from the same crown are placed at great disadvantage; but ultimately some good shoots, but none of the very small ones, should be left to grow up. Where common salt has been employed as manure, the Asparagus will be found earlier and better; the cutting, however, ought not to be continued in this case so late as is usually done under ordinary circumstances. *Broccoli*, make a principal sowing of all the late and spring sorts, such as Portsmouth, Sulphur, Dwarf Late White, Knight's Protecting, Clarke's Early White, Walcheren, and Somers' Particular Late White; the latter will form the last link between the late spring Broccoli and the hand-glass Cauliflowers. Sow *Chervil*, *Chicory*, and a bed of *Sweet Marjoram* on a warm slope—this plant is much hardier than Basil, and will do very well in this way; also, *Carrots* for drawing young, *German Greens*, *Savoys*, *Radishes*, *Lettuces*, and successions of *Peas* and *Beans*.

FRUIT GARDEN.

It may be observed that portions of shoots of Apricots which had been surrounded by the shreds in the preceding summer have been more injured by the frost than the adjoining portions. The shreds employed for fastening the summer shoots should, therefore, be of good quality, in order that very narrow strips may suffice, and no more should be employed than is absolutely required. Plenty of room should be allowed, and the leaves should hang free, and not be bundled along with the shoots. Walls are expensive, and every gardener ought to keep a good face upon them as long as possible, by not driving nails farther in than is necessary. For summer nailing it will generally be sufficient that merely the point of the nail be inserted, just enough to hold, but rarely farther than would render difficult its removal by the finger and thumb. With regard to driving nails in the face of the brick, that is quite inexcusable. Water effectually all trees that require it. If only a little rain fall, insufficient to reach the roots, so much the more will the trees suffer on the return of dry weather, an expanded foliage being induced, requiring an increased supply of moisture which the roots are not in a condition to give, if judicious watering be not attended to.

FLOWER GARDEN.

Of course, manuring and dressing will proceed in an orderly way. High-dressed ground should be mowed at least once a-week at this period, for a well-kept lawn is a most pleasing object. Let the dressing of all herbaceous or mixed beds and borders be finished without delay, and prepare stations where blanks exist to receive Verbenas, Fuchsias, Heliotropes, Calceolarias, &c., now in the course of hardening off for this purpose, and for forming masses. Self-sown annuals, the Mimulus family, the

Forget-me-not, and other useful little flowers, as also Pansies, may be transferred with balls, to fill up blanks. See that runners of the Neapolitan Violet are provided for the next winter. Many excellent herbaceous plants have been lost or rejected to make way for novelties. Auriculas are now in full flower, and in order to prolong the bloom it will be necessary to remove them from the frames to a north-east or northern aspect, protecting them from rain by an awning of calico. When seed of fine quality is a desideratum, artificial impregnation may be resorted to. As seedlings attain a sufficient size to handle, prick them out into store-pans. If Polyanthuses are grown in beds and are intended for exhibition, the plants should be lifted with a ball of soil and potted overnight, at the same time watering well; they may be returned to their places after the competition is over, sustaining little or no injury by the removal. Tulips are now colouring fast and when sufficiently forward should be partially shaded, and especially protected from hail storms, which usually occur at this time. Support those requiring it with neat sticks, and keep the bed free from weeds. Insert the whole of the sticks intended for the support of the flower-stems of Carnations. Late-planted layers must be carefully attended to. If the beds of Pinks are not already top-dressed let it be done without delay. Continue to pot-off rooted cuttings of Dahlias, and harden those already potted. Pansies may now be readily propagated by the small side-shoots. Prick them out under a hand-glass on a shady border.

GREENHOUSE AND CONSERVATORY.

No tribe of plants is better adapted to keep up a constant display than Azaleas. The numerous varieties of Azalea indica are remarkable for brilliancy, whilst the hardy American species delight with their agreeable fragrance. The principles followed with regard to the Camellia to produce winter flowers, are in the main applicable to the Azalea indica. Forcing into wood betimes in the spring, a trifling amount of check to form the bud, and a partial rest for a considerable time before excitement, are the main features. The Azalea, however, will do with more heat than the Camellia, and with rather less shading. Plants intended for flowering next January and February should be forced into growth without delay. The early-flowering plants of Primula sinensis, now exhausted, should be removed to a cold pit or frame; likewise early-bloomed Cinerarias or other fading stock. It is of the utmost importance to have a pit or frame for this purpose, as it enables the cultivator to thin out the remaining stock now in rapid growth. Pelargoniums will now be making rapid progress, and the early plants will now be coming into flower. Attend to tying them neatly, and never allow them to suffer for want of water, and even a little manure water will benefit them. Keep the foliage free from dust, by syringing and washing, in order that the leaves and flowers may be shown to the best advantage.

STOVE.

Attend to shifting all the free-growing plants, which will now be making great progress, such as Clerodendrons, Gloxinias, Gesneras, and similar showy kinds which contribute to the decoration of the stoves and even greenhouses in summer and autumn. The great art in cultivating these plants is never to allow them to flag for a moment, but to keep them in rapid growth by an abundant supply of heat and moisture, and occasional shading in scorching sunshine, until their flowers appear: they may then be gradually exposed to more air and a lower temperature. Follow up frequent syringing to stove plants in general morning and evening. Do not suffer plants to become crowded, or weakness will be the certain result. If any room can be spared in the other plant-structures, a few of the commoner or hardier kinds should be removed. Continue to increase the temperature gradually, more especially when it can be done by solar heat, accompanied by a very considerable amount of atmospheric moisture. This will be best accomplished from three in the afternoon till six, when the thermometer may sink to 65° for the night.

PITS AND FRAMES.

Annuals that were sown last month will now require to be potted off. German Asters, &c., might be pricked-out in beds, under mats supported by hoops, previous to transplanting. Stocks and other annuals might be pricked out in the same way. Pot-off tender annuals, with Convolvulus major and minor, into pots, and protect them under glass until all danger from frost is over. Tender plants that were potted off early should be shifted if they require it; for if they get pot-bound before being planted-out they seldom succeed so well afterwards. Continue to increase the stock of Verbenas, Heliotropes, Salvias, Fuchsias, and all similar plants that may be required for filling boxes, vases, and blanks in the beds or borders in June.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Slugs and Snails.—The weather has brought out these from their lurking-holes in vast numbers. A hard, black-backed, yellow-bellied kind, which nothing will settle but catching and killing, has been holding high-festival peregrinations on the hardest walks of the kitchen garden, and the quickest and best way to destroy them is to pick them up on a dewy or damp warm morning, and dispose of them according to fancy and taste. If not sharply looked after, the common slugs and black and striped snails would soon make short work of all crops of Lettuce, Turnips, &c., just as they come through the ground. Where there is reason to suspect that they abound in the soil, a sprinkling of salt scattered over the ground about three weeks before sowing is good. In such moist weather, when slugs will be sure to attack young seedlings, a slight dusting of powdered quicklime will be a good protection, so long as the lime remains quick; but when by exposure it becomes mild, or chalk, it offers no more inconvenience to their moist bodies than so much soil. When thrown on the young plants, and the lime is very fresh, it is as well to mix it with equal parts of burnt earth, wood ashes from the men's fire-place, or roughish coal ashes from which the dust and the larger pieces are excluded. Finely-sifted ashes are of no use, but if the ashes are somewhat rough, ranging chiefly from the size of Radish seeds to that of the smallest Peas, the rough angularities of the ashes will distress the slugs very much; and even such will be more efficacious if a little fresh soot is added, one advantage of which is, that whilst the ammonia it holds is distasteful to the depredators, there is not a crop out of doors that will not be the better of all such dressings with soot, and for the manuring process it should be applied like guano just before rain is expected. For keeping off slugs and snails, the longer the soot remains dry the better. Where labour can be spared, there is nothing so effectual for keeping such slimy enemies as slugs and snails at bay as picking them up early in the morning, and this will be much facilitated if little mounds of brewers' grains or greased Cabbage leaves are laid down the evening before. These, however, should be examined early, if before daybreak all the better, and a sharp boy paid for the work is the best for the purpose.

Cucumbers.—The brighter weather and the smoking seem to have arrested the fly, and the production is everything that could be wished. In the frames snails have been more than usually troublesome; and in some small pots, with a bit of Potato or Carrot in them, and covered with dry hay, we have caught a good many, though very few woodlice, for which we had set the traps, and that in circumstances where we would have expected to find them, as it is almost impossible for an old garden to be free from them, especially when fermenting material is used for forcing. Potted-off plants intended for ridges and pickling, and put them under glass, where there was just a little heat. We have tried these hardier plants many ways, but, except in warm seasons, we could not do much with them on the plan followed at Maldon, Sandy, and Biggleswade, from which places so many Gherkins and short Cucumbers for salad find their way to the London market, and prove a very profitable crop. There the growers generally sow them in rows, some 4 feet apart, like Peas, but shallow, in the first fortnight of May: and all they do to them in a good season is to thin them out like Turnips, let them grow as they like, and gather the fruit. One of the oldest and best plans we have followed in cold places is to make a ridge of fermenting material from 2½ to 3 feet in height and 4 feet wide, place 10 or 12 inches of soil on it, plant under hand-lights, remove them when the plants are established, and let the plants run over and down the sides of the ridges, and almost as far as they like. If such ridges can be formed in the first week in May it is best to sow four or five seeds under each hand-light, as the plants then sustain no check. The next best method is to dig a trench 18 inches deep, fill with hot dung a little higher, and then throw back the most of the soil. The advantage of the first mode, where the ridge is all above ground, is, that in a wet autumn the plants will suffer little from the damp. The third best plan, where the open ground is resorted to, is to dig holes—say 4 or 5 feet apart, and put a good

barrow-load or more of hot dung in the hole before replacing the soil.

Vegetable Marrow.—After trying almost all the warted, and wrinkled sorts of Vegetable Marrow, we have gone back to the old common sort, long-shaped, and yellow when ripe. No other of the family, nor of the whole group of Gourds, beats it for richness of flavour, according to our fancy. Treat as ridge Cucumbers.

Sea-kale.—A correspondent writes that he is obliged for the rough modes of obtaining supplies of this delicious vegetable, which were lately described, but he cannot perceive the use of his placing dry litter or rough hay inside a garden-pot before placing it over the plants to be blanched; nor yet do we, as he covers the outside of the pot with litter. (See page 299 for reasons.) All we can say is, that we never cut finer or whiter. We are, however, obliged for the criticism, as it enables us to advise that in planting in rows 2 feet apart, the plants should not be less than 12 inches apart in the row, instead of 6 or 8 inches as stated in the page referred to, and that more especially, if the plants are to have two summers' growth before being taken up for forcing. We have just examined a piece so planted two years ago, and with small seedling plants. Each of these yielded a good head in the following spring. The cutting-off the crown or strong shoot caused a number of buds to sprout instead of die; and even though these were thinned, we find that the plants now are meeting each other in the row, and will be excellent for taking up for forcing next season, and thus we shall avoid all trouble with fermenting material on the beds.

The sight of these rows brought to our mind another simple mode of obtaining fine clean Sea-kale out of doors in spring without fermenting material—viz., the having triangular wooden boxes, something of the make of Mr. Rivers's curate's vinery—say 20 inches at the open base and 15 inches high at the ridge, the two sloping sides formed of stout wood tongued together, each piece to be from 4 to 6 feet in length. One side might be hinged to the ridge-board, so that the crop could be gathered without trouble. The chief objection to such boxes would be their expense, and principally on account of the strength of the wood, as, if the boards were thin, they would gape and shrink when exposed to a hot sun, and thus the light would find its way in and spoil the blanching. We once tried a lot of small oyster-barrels reversed over the crowns, and if these barrels had been covered with litter, they would have done as well, and been more safe, than regular Sea-kale earthenware pots; but when exposed to the sun they were of little use, as there were soon plenty of small openings between the staves.

Another correspondent is afraid if he covered his bed with fermenting material and tree leaves, without any pots or boxes over the beds, that the growth would become drawn up and be spoiled in flavour. We agree that rank fermenting dung would be apt to injure the flavour; but fresh tree leaves will afford ample heat, and the shoots of the Sea-kale as it rises through them will be little if at all injured in flavour. As for spindling, however caused, the produce will be watery if the heads are much more than 6 inches in length. This length may be considered a good average. If less than that, and strong and sturdy, from 1 to 1½ or 2 inches in diameter at the base, all the richer and better the flavour. In planting the fresh piece referred to last week, we put the plants out 1 foot apart, in rows 2 feet from row to row.

After such statements, we think that the smallest garden may have its little plot of Sea-kale, as well as its piece of Rhubarb and Parsley. We shall have sown what Sea-kale seed we have before this is printed, and fly and birds must be looked after, or they will make short work of the first of the young plants, and the last of the seeds, just as they begin to germinate. Wood ashes, &c., and a net will be required where birds are troublesome.

Asparagus.—We shall sow seeds, and plant out a piece at once. As a fact in favour of planting in rows instead of beds, and as it were on the crown of the ridge, and thus keeping the plants all along comparatively near the surface, we may mention that we gathered plentifully a week ago from such a piece, whilst scarcely a shoot appeared on a piece intended for forcing next year, and which had been planted more in the bed and covered deeper. Those who can spare a little dung for surface-manuring every year, may have good serviceable Asparagus without what so many dread—the burying of large quantities of manure in the soil at great depths, and making more ado with an Asparagus-bed than if it were a Vine border to last a century. In all cold clayey loamy soils, however, if the largest heads are to be aimed at, draining and deep stirring must be practised, and light soil must be procured to imitate the deep rich sandy loams in which the Asparagus naturally flourishes.

Scattered salt twice between the rows, and did the same to the fresh-planted Sea-kale. Will cut as little as possible from the old piece of Asparagus referred to above, but will pretty well allow all to come, and then the buds will be sooner matured, and therefore more obedient to heat when applied at the end of autumn. In making fresh plantations we prefer two-year-old plants, and those one year old to those which are more than two years. As stated the other week, we like the plants to be 3 inches or so in height, and as the roots are spread out they should never be dry, but be kept in a damp mat whilst planting goes on.

Turnips.—From a bed sown under a glass protection we have thinned out the most sturdy plants, and transferred them to a south border, pricking them out in rows 15 inches apart, and 6 inches in the row. This is a good mode of obtaining early Turnips easily, as the plants are beyond the reach of the fly, and it would require some large snails to crop them over. We find the common Turnips for table transplant as well as the Swedes.

Pursued the routine of pricking-out Celery and Cauliflower; the advantage of doing so with the latter is that the plants are strong before being finally planted out with a trowel, and thus are better able to bid defiance to all enemies.

FRUIT DEPARTMENT.

The chief work has been thinning Grapes, arranging Vines, and thinning shoots in the late vinery and orchard-house, removing Strawberry plants and introducing fresh, and as soon as we can find time we shall throw up a slight hotbed, as alluded to last week, lift a lot of young plants pricked out on a border last autumn, and cover the bed with old sashes. Our doing so will free the houses after a time of Strawberries, and keep up the succession until they come in from out of doors, but which we do not expect them to do for six weeks.

Orchard-houses.—Strawberry plants in the first orchard-house are in full bloom, and in the second are but little more forward than those out of doors. In the first Tom Thumb Pea is podding well in a row of pots at the foot of the back wall, whilst Dillistone's, or a sort very much like it, sown within a yard of the first, and allowed to cover the ground behind two rows of Strawberries in pots, is in full bloom, and will no doubt do well. In the second house buds are forming on a similar row of Peas, but we expect the first week of May will be gone before many flowers show or open, and the present appearance would lead us to the conclusion that they would not be more than a week or ten days in advance of those turned out in the open border. The latter house, on account of Plums and Cherries in pots, has been kept very open, and only shut on cold nights, or in very high winds. The Peaches against the north wall have set very thickly, and we have disbudded twice; and the Cherries are setting, and neither they nor Apricots will set without plenty of air. The first house contains chiefly Peach and Nectarine trees against the back wall, Peach and Fig trees in pots in front, and Vines planted near the front inside, and for which, if we keep them, we must make a border outside beneath the walk which runs in front of them, and they well deserve it, if the pot plants should be removed. This house had less air, even when the trees were in bloom, though a regular circulation; and as the fruit set sooner, the house was kept warmer by giving only a little air early and not the full quantity even in sunshine, except when very bright, shutting up between three and four o'clock in the afternoon, and if cloudy even earlier than that. In cold weather, we put a fire in the iron stove in the house, and though it is a rough, tinkered-up affair, nothing could answer better, and for such a purpose no other plan of securing a regular genial heat will come near it for economy and simplicity. By this means the house, except in cold nights, will now average from 50° to 55° at night, and from 60° to 65° in dull days, and provided air, however little, is given early, we do not mind if the temperature rises gradually to from 75° to 85° with sun heat; but if likely to go higher at this season, we add a little more air, chiefly at the top of the house. Of course, as the sun gains power by-and-by, all the air possible will be needed at mid-day. By such modes the one house will be pretty well cleared before the other comes on.

We are not surprised that orchard-houses are such a source of pleasure and profit to amateurs, for even the watering and other attention bestowed on trees in pots, which become a drag to the gardener, are to amateurs sources of interest and healthy

enjoyment. A visitor lately wished we would say how this house was filled up, though it does not furnish any rare example of the cramming system at this season. The house is a lean-to, height at back, 10½ feet; in front, 3½ feet; the front supported by wooden posts, and consisting of 12 inches of glass, all wood below; wooden ventilators, hinged. Sixteen inches from the back wall is a trellised wooden pathway, 16 inches wide, and in front are two rows of trees in pots, and sometimes more. In front of the pathway in winter, Lettuces, Endive, &c., were put, and Strawberries in pots were kept secure. Between the pathway and the first row of trees, Potatoes in pots were brought from a bed as soon as the temperature in the house rendered it safe, and these, after being fingered for the earliest tubers, are now taken out and placed under some Spruce trees that have no branches within 6 feet of the ground, and where they will have a fair portion of sun without being liable to frosts, as some Laurel branches have been stuck in behind them to break the north winds; thus placed they will yet afford good gatherings. Between the wall and the pathway there is the row of pots of Tom Thumb Pea. Close to the front there are two rows of Strawberries in pots, the one row standing 4 inches above, and the other on a layer of turf. About 3 feet from the front is the row of Peas with a line of twigs behind them to prevent them going back, and so forcing them to go to the front along the ground, which causes all the blossoms to stand upright, and the pods too are easily seen. Between the Peas and the Strawberries, until lately, there was a row of Kidney Beans in 10-inch pots; but the Peas, as they grew, required that they should be removed to a late vinery, which we could not keep longer without shutting it up. From these Peas back to the wooden pathway, wherever there was a vacant space among the pots, it has been filled with bedding plants requiring to be pushed on a little before being thoroughly hardened off, so that the 16 inches of pathway is at present the only empty space in the house, and the only drawback is that ladies can scarcely venture along with their ample garments.

Before filling the centre of the house with these temporary inmates in the shape of bedding plants, &c., the ground for the front half of the house was well watered with liquid manure, as in such a house we prefer watering at two or three times, beginning at the back wall first, and with intervals of some days between them. In this house we discovered on four or five twigs our old enemy Aphis persicæ, and either removed them or washed with soap water and quassia water with a brush; and as yet we have seen no trace of other insects. After shutting up in the afternoon, and especially if sunny, we frequently syringe with weak soot water, as clear and bright as coloured brandy. When we shall have taken the bedding plants and the Peas out, we shall have little on the floor during the summer, and then where the trees do not shade, the sun's rays will have the chance of reaching the ground—a matter of more importance than is generally imagined. This is merely a slight sketch of what an amateur might obtain from such a house and yet keep it at all times neat and interesting.

ORNAMENTAL DEPARTMENT.

The work was chiefly a repetition of that of previous weeks—potting, pricking out, and cutting-making. We were very much hindered in putting Calceolarias into temporary beds on account of these beds having been soaked with rain, and we dislike planting in such wet soil.—R. F.

COVENT GARDEN MARKET.—May 1.

We have again to report a downward tendency in the prices here, owing to the supply now considerably exceeding the demand in forced fruit; and foreign importations have very much increased, comprising Potatoes, Kidney Beans, Artichokes, Tomatoes, Asparagus, Salading, Cherries, and Apricots.

TRADE CATALOGUES RECEIVED.

Eliza Abraham, Fort Prospect Nurseries, Limerick.—*Catalogue of Bedding Plants and Florists' Flowers.*

J. Carter & Co., 237, 238, and 261, High Holborn, London, W.C.—*Gardener's and Farmer's Vade-Mecum. Part III.—Stove, Greenhouse, and Bedding Plants.*

T. S. Ware, Hale Farm Nurseries, Tottenham, London, N.—*Catalogue of Roses, Soft-wooded Bedding, Herbaceous, and Border Plants.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Anemone pulsatilla (*A. R. C.*).—Any florist who advertises in our columns could supply this native plant. We know that Messrs. Henderson have it.

Cleome integrifolia (*F. S. N.*).—We do not know where seed of the American bee plant, Cleome integrifolia, is to be had. Probably at Chicago.

Books (*A Constant Subscriber*).—If by "a botanical dictionary" you mean a dictionary explaining the terms used in botany, Henslow's "Dictionary of Botanical Terms" will suit you. (*M. W.*).—"The Vine Manual" contains much upon early forcing. You can have it free by post from our office if you enclose thirty-two stamps with your address. (*M. H.*).—The price of Mr. Salter's work on the Chrysanthemum is 5*s.*

Exhibition of Tricolored Pelargoniums (*T. W. Johnson*).—It is to be at the Royal Horticultural Society's garden, at South Kensington, on May 21st, and the public will be admitted by paying 2*s.* 6*d.*

Spent Hops and Malt Combs for Mulching (*Vitis*).—We have known spent hops used as a covering for the Strawberry-bed to keep off slugs, and to answer the purpose of litter in keeping the fruit clean, &c. They do not injure the flavour of fruit. Malt combs we have also known used as a mulching for the Vine-border. Whether the roots will take to it in preference to anything else we cannot say, as we know of no experiments on the subject.

Verbenas for Exhibition (*W. W.*).—Foxhunter, Charles Turner, Géant des Batailles, Madame Hermann Stenger, Annie, Mauve Queen, Snowball, Lilac King, Admiral of the Blue, Wonderful, Black Prince, and Rose Imperial. To these you may add, if you do not object to the higher price, some of Mr. C. J. Perry's fine new varieties.

Substitute for Glass (——).—Oiled paper was formerly employed; but this has been superseded by linen or calico dressed with the following preparation:— Old pale linseed-oil, three pints; sugar of lead (acetate of lead), 1 oz; white resin, 4 ozs. Grind the acetate with a little of the oil, then add the rest and the resin. Incorporate thoroughly in a large iron pot over a gentle fire; and, with a large brush, apply hot to a fine calico stretched loosely previously, by means of tacks, upon the frame. On the following day it is fit for use, and may be either done over a second time or tacked on tightly to remain. Cucumbers and Melons may be grown under such frames, but they require much more attention than when glass is employed, the plants are so liable to be drawn and unfruitful.

Double Wallflowers—"S." inquires if there is still in existence a good double dark self Wallflower; as the only sort he can obtain is flaked with yellow and not worth growing, though sold generally under the name of double blood red.

Driving away Ants (*A Subscriber, Waterloo*).—You may drive away the black ants by scattering a little guano, or by pouring ammoniacal liquor over their haunts.

PRUNING RHODODENDRONS (*K.*).—To secure the branches, or rather the dormant eyes upon these, breaking well, you should cut the plants down by the end of May; and if you reduce them much it would be better to do so early in the same month. If you cut the plants in much they will not flower in the following year. As regards the hybrid scarlet varieties, we would let them flower, and then cut them in as required; but you must not expect them to flower much during the next two seasons.

LAWN THIN AT BOTTOM (*E. N.*).—Sow over the lawn Suckling Clover (Tritolium minus), at the rate of 8 lbs. per acre, and after sowing run an iron rake over it lightly, and roll well. Allow the grass to grow until July, then mow it, and keep it well rolled and mown every three weeks until October; then leave off mowing, but roll well once a-week.

DESTROYING MOLES (*Idem*).—The only effectual mode is to trap them. Green elder leaves placed in their runs are said to drive them away.

VIOLA CORNUTA PLANTING (*W. S.*).—You should allow 9 inches from plant to plant, the same distance from the side of the bed, and 1 foot from the Pelargoniums.

PEACH TREE SHEDDING ITS FRUIT (*J. T. M.*).—From your description of the treatment we should attribute the evil to lifting the tree; and its roots, being like so many bare branches, would be insufficient for the support of the fruit. We should have preferred lifting the tree at one operation instead of partly last year and partly this. The crop would not have fallen had you lifted the tree early in autumn, if the wood was well ripened last year; but from your account of the state of the roots this could hardly be the case, and the fruit would fall on that account quite as much as from the lifting.

RETURFING A CROQUET GROUND (*S. J. A.*).—To level and dig the ground, lay and beat the turf, would take an active man a fortnight to do the work well; but all depends upon the amount of levelling necessary.

SUPERPHOSPHATE OF LIME (*A Recent Subscriber*).—It should be applied in a solid form, a fair-sized handful being placed around the plant or shrub, and pointed in with a fork. You may also apply it to any kitchen garden crop, more particularly Turnips and Cabbages, at the rate of 4 cwt per acre.

PEAR TREES NOT BLOSSOMING (*Idem*).—We can only account for your trees not blossoming from the soil being different, and the treatment may also vary, but on neither point do you furnish any data.

WATERING NEWLY PLANTED HOLLIES (*A Subscriber*).—The newly planted Hollies which you have watered overhead, and of which the leaves are brown and the bark shrivelling, are likely to die. The watering overhead would not cause the leaves to become brown, and it would help to keep the bark from shrinking; but with the late showery weather we think it would do more harm than good, as by keeping the soil in a saturated condition it would tend to hinder rooting. We would water only during dry weather, and occasionally overhead; but if the bark is shrivelled and brown it is all over with the trees. The falling of the leaves does not matter if the wood remains green and plump.

SCREEN UNDER LIME TREES (*L. P.*).—Nothing would serve so well as Aucubas. Yew would also answer the purpose, but is of slower growth. The Aucubas should be strong plants from 2½ to 3 feet high, and should be planted as much apart. Privet, we fear, would not answer your purpose, as it grows but moderately, and is thin under trees.

GOLDEN FERNS NOT THRIVING (*P. M. Shuttleworth*).—It is not unusual for Golden and Silver Ferns to lose their young fronds after repotting. This is more commonly the case with old plants whose roots have been reduced at the repotting. All will come right when the roots are working freely in the fresh soil and reach the sides of the pots; but when we find plants in this condition we have young plants in a forward state to take their place. Old plants are not worth keeping more than one or two years after they become specimens. They become weak, and are impatient of repotting.

PIMELEAS AFTER FLOWERING (*M. H.*).—When the flowering is over they should be cut back to within an inch or two of the old wood and be kept rather dry at the root until they have broken and made shoots an inch or two long, when they may be repotted in a compost of two-thirds sandy peat and one-third turfy loam, adding silver sand liberally, and providing good drainage. They should be kept rather close, shaded, and sprinkled overhead until they recover the potting, and be careful not to overwater until the roots are working freely in the new soil, which should, however, be kept moist; afterwards give water more freely, but never until it is required, then afford a good supply. The plants cannot have too much air and light. They will do better in a cold pit in summer than in a greenhouse.

CASSIA CORYMBOSA (*Idem*).—Your plant with numerous soft young side shoots should be removed to the greenhouse; and if it has too many shoots they may be reduced in number by dishudding or rubbing away the weakest and worst situated. The plant will most probably flower in August. Its season of blooming depends on the treatment, but is generally from May to August. We cannot determine the names of the Begonia and Fern; to enable us to do so we must have better specimens, and in flower or fruit.

NETTING FOR COVERING A FRUIT GARDEN (*S. A. N.*).—We should recommend netting with three-quarter-inch meshes, or if at some distance from the trees, inch meshes would not be too wide. Any of the firms advertising in our columns would no doubt serve you well. We cannot recommend dealers.

STRIKING AUCUBA CUTTINGS (*J. H. H.*).—You may put in cuttings of the present year's shoots in August, or when the wood has become a little hardened; and they would do well in small pots placed in gentle heat, but it is not necessary to cover them with a bell-glass. They strike with certainty and freely in a cold frame.

WATER IMPREGNATED WITH IRON (*Fenwick*).—Water but slightly impregnated with iron will not injure the plants to any great extent.

POA TRIVIALIS (*Inem*).—It is about equal in habit to Dactylis glomerata variegata, and is as easy of propagation.

OSMUNDA REGALIS (*A. H. D.*).—The Osmunda does very well planted in a pot, if well watered during the season of growth, and we have no doubt that it would succeed well if the pot in which it is growing were placed in one considerably larger, and the space between kept full of water for a time in summer. We have not tried this plan, but we have kept the pot in a saucer of water with satisfactory results.

TREATMENT OF LILIES OF THE VALLEY AFTER FLOWERING (*N. R. B.*).—You may plant them out of the pots in an east or west border, or other shady but open situation, or you may plunge the pots to the rim in such a border, and keep the plants well watered until the foliage turns yellow, when watering may be discontinued. We have not tried withholding water until they are required for forcing again; in fact we do not force the same plants two years in succession, and if we did so we anticipate an abundant crop of leaves would be the result.

PRUNUS SINENSIS FLORE PLENO AFTER FLOWERING (*Idem*).—The plant should be continued in a light and airy part of the greenhouse until the end of May, when it may be plunged out of doors in coal ashes in an open sunny situation, and be kept well watered throughout the summer. If it requires repotting this may be done when the leaves turn yellow. It is a hardy deciduous flowering shrub.

LILIUM AURATUM IMPORTED *versus* HOME-RAISED BULBS (*C. C. E.*).—The imported bulbs, because they are of flowering size are preferable to those raised in England; but we fail to recognise the assumed superiority. In our opinion English-raised bulbs are as good, if not better.

RHUBARB RUNNING TO SEED (*C. C. E.*).—The only means of preventing the plants forming seed-stalks is to divide the crowns every three or four years, and that cannot be done without weakening them or lessening the produce. The plants are more apt to run to seed in light poor soils than when growing in rich and heavy soil. The best means to adopt is to afford rich soil and plenty of manure, and to cut off the flower-stalks at the first eye from the ground before they have grown more than a foot in height.

HUMEAS DYING (*Edmund*).—The removal of the lower leaves is sufficient to account for the plants dying off as you describe, as in stripping off the leaves the stems would have their outer skin removed. The same results follow potting this plant deeper in the soil than it was before, for then the stem decays where in contact with the soil.

PELARGONIUM LEAVES BLACKENED (*A. S. A.*).—The blackness of the leaves sent was caused by the Cinerarias or plants near being infested with aphides or thrips, but we think the former, there being a deposit of those insects upon the leaves. The house should be fumigated with tobacco on two consecutive evenings when the leaves of the plants are dry, shutting it up closely, and choosing a calm evening for the operation. The plants may be syringed in the morning. It may be necessary to repeat the fumigation in a few days, indeed, in Cineraria culture fumigation is absolutely necessary, for all depends on the plants being kept free of insects. Fill the house so full of smoke that a plant cannot be seen from the outside.

CAMELLIAS UNHEALTHY (*L. H.*).—The Camellias, judging from the specimen sent, are in a very sickly condition. The leaves are yellow and blotched with brown, as if they had been constantly syringed or had had water dripping and hanging on them. The cause of the bad condition of the plants may be keeping the atmosphere much too close and damp in winter, but more probably the unhealthy state of the roots, which we apprehend are inactive and situated in wet sour soil. We advise you to have the plants repotted at once, using turf from a sandy pasture, cut from 1 to 1½ inch thick. In potting them, pull the turf in pieces and press it rather tightly. Remove as much of the old soil as can be done without injuring the roots seriously. Good drainage is essential.

INSERTING MUSHROOM SPAWN IN FIELDS (*E. S.*).—The best time for inserting Mushroom spawn in a grass field would be from the middle to the end of May. Pinching back the shoots of fruit trees on Mr. Rivers's plan will not cause premature decay, but if you want more strength allow the shoots to grow a little more.

VINE LEAVES (*A Subscriber*).—What you call "withered" is only the corrugated appearance which leaves assume when they do not grow fast enough to elaborate the sap supplied to them. Keep the air of the house moister.

FIRE INSIDE A VINERY (*J. H. J.*).—As your flue is heated by a fire inside your house you must use no damper, and in clearing out the ashpit you will require to damp the ashes, &c., to prevent dust and smoke finding their way into the house. To make secure, however, your best plan would be to surround the fireplace with a wooden box with a close-fitting door, and shut this door after you on doing anything to the fire. You need then have no dust in your house. This is more necessary in your case than when a house is heated by a stove inside the house, as if in the latter case there is but a short horizontal pipe there will be no back draught as sometimes happens with a flue.

VARIOUS (*Dagmar*).—Viola cornuta is good for bedding and edgings. It is raised by seeds, but is best propagated by cuttings The bit of flower sent looks like Honesty. It is of no use sending bits daubed on a letter. They should be sent separately in oiled paper, and if particular in a box. The leaf is like that of Begonia rotundifolia. Fern too far gone. Nemophila insignis may be mixed with the Lobelia. The Nemophila will flower at once, and will be fully over before the Lobelia is in its beauty. Lobelia speciosa may be sown now in a hotbed, but it is late enough. The plants should want pricking off at the latest by the time this appears. We think the proposed arrangement for the spring flower garden will look very well. As to plans No. 1 and No. 2, we would have preferred that all the beds had been numbered and the lists drawn out separately. When marked by writing on the beds it becomes confusing, and requires more time to look over. Of the two arrangements we prefer the second, because it is more simple and will longer continue in perfection. No. 1 would look best in early summer, but Tropæolums, Calceolarias, Gazania, Linum, and Petunias, would be almost the only flowers that would stand through the autumn. Moreover, you could keep up your Pansy-beds by pruning, manuring, and watering, or by ensuring fresh plants from seed sown now. You could also renew your Nemophila-beds, and even the Saponaria, if the first beds bloom early, by fresh plants in pots, or China Asters lifted. The plan No. 2 is not only simpler, but each bed is distinct without edgings, a matter of importance with some of these annuals, as even Saponaria, compact as a bed, is poor when kept in shape and line, as a centre or as an edging. With the exception of the Nemophila most of the other plants will stand through the autumn, if, at least, part of the seed-pods are removed; but unless you raise the Coreopsis, Jacobæa, &c., under protection and plant out, you will not have your beds so early in bloom as in plan No. 1. You do not say whether you sow in the beds or plant out. We have had splendid beds of Saponaria when planted in patches at regular distances; also of Coreopsis, Œnothera, &c.

Ribbon Border (*Constant Subscriber*).—Perilla or Amaranthus would do between the scarlets, in the ribbon border referred to at page 256, either separately or mixed. Then what would you say to this arrangement?—Scarlet Pelargonium, Perilla, Yellow Calceolaria, Tom Thumb, Purple Verbena, and Cerastium. The leaves of the white plant were much faded, and they are almost large enough for a Centaurea; but from the creeping habit we judged it to be an Arctotis. It would do for a front row, but generally it is best for carpeting a bed. It will not be so compact as Cerastium.

Flower-beds (*Fred*).—In your proposed bedding we approve of the first three arrangements. In No. 4 we would arrange thus:—Ageratum mexicanum, Scarlet Calceolaria, Centaurea, Crimson King Verbena. In No. 5 we would plant thus:—Yellow Calceolaria, Iresine, Bijou Pelargonium, Forget-me-not. As to the ribbon border, the arrangement will do very well; but you will require strong plants of Iresine to match in height with Salvia patens. We fancy Perilla would suit better for height. If the beds are in fair order they will not need such manuring, but if very poor you might add bone dust, or super-phosphate, about 4 ozs. to the yard, and that we would confine to within an inch or two of the surface. The most of the plants you have named would do well 1 feet apart—Bijou Pelargonium, if rather small, 9 inches; Forget-me-not, 6 inches; and Cerastium, 4 inches, or if small, 3 inches.

Propagating Iresine Herbstii (*Dagmar*).—It is best raised from cuttings, and propagates freely, but should be kept in a place warmer than a cool greenhouse in winter.

House for Fruit (*J. H. H.*).—Your proposed house 12 feet high at back. 5 feet high in front, width not stated, but having a pathway down the middle, a platform of slate on each side, supported by walls 2½ feet in height, with two four-inch pipes below on each side, and two four-inch pipes along one side of the pathway, will be very useful for many purposes. 1, The back platform will do for Melons and Cucumbers grown in pots and trained to a trellis on a level with the rims of the pots, if you have nothing higher on the front platform; but they would do better, give more room on the back platform, and enable you to have higher plants in front, if the Cucumbers and Melons were each trained to a single stem until they reached 18 inches from the glass, and were then topped and allowed to spread over wires at that distance from the glass. 2, You can have Fig and Orange trees in pots on the front platform; but if we wished to grow them fine, we would have the house in three divisions, and grow Melons in one, Cucumbers in another, and Figs and Orange trees in a third. 3, Vines can be brought through the front wall of such a house, planted 5 feet apart, and two rods taken from each as you propose, but when the Vines occupy the house, you could do no good with anything beneath them when fully established and in full leaf. You might have early or winter Cucumbers in such a house before introducing the Vines, but in that case the Vines had better go in above the wall-plate; or at any rate have double sashes or a wall of wood about 2 feet inside of the front glass, so that the Vines might be kept there, and cool, before you wanted to introduce them. 4, A south-east aspect will do, but a south-west one we should, if anything, prefer. It is early to lose the sun by one o'clock. We should not mind it for pot plants, but for early Cucumbers, it is important to have more sun. However, they would do. 5, With only two pipes exposed for top heat it will be well, if early work is contemplated, either to have two more pipes or to have openings into the chamber to let the heat out when wanted. 6, Two four-inch pipes round the front and two ends of a house 12 or 14 feet wide and 30 feet long, will do for a vinery where the Grapes would come in in September with little forcing. To have them in July and August, you would require three pipes as two flows and one return. To have them early you would require four or five pipes.

Mealy Bug (*E. S. D.*).—We know of no means of destroying the mealy bug on your Vines now, except constant washing with soap or glue water, and that will only keep the pest under a little. In places swarming with it, as yours is said to be, it is most likely that the walls, and stages, and shelves are infested. We have seen slate stages taken up and on every bearer you could scrape off the insects in handfuls, and hence all temporary expedients proved unavailing. In such circumstances we would thoroughly clean out one house, then we would shut it up closely and smoke it for forty-eight hours with turpentine and sulphur burned, which, of course, would destroy every green thing and all animal life. We would then wash the house all over with boiling water holding soap in solution, dash it into every joint, and when dry and exposed, fresh paint and clean. We would next bring in the plants that were cleaned, by cutting them back and bathing their tops and roots, and then fresh potting in a moist heat. For the present we knew no remedy but washing, and that will only be a palliative. We never found smoking with tobacco of much use.

Names of Plants (*W.*).—Æschynanthus maculatus. (*J. P., Reigate*).—1, three varieties of Primula villosa; 4, a garden Anemone. (*J. T., Morpeth*).—Selaginella Martensii var. (*An Old Subscriber, Kingston*).—Arctostaphyles tomentosa. (*Primula veris*).—Incomparable Orange Double Jonquil.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending April 30th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BREEDING DARK BRAHMA POOTRAS.

I had fully intended the article on vulture hocks to be my last upon the above subject, but some of the letters which my papers have called forth appear to make a very few further remarks desirable.

My object in writing has been to raise the standard of this truly splendid breed, and in particular to draw attention to the Dorking taint now so very prevalent; to point out the general degeneracy of form and size; to insist upon better combs and leg-feathering; and to seek after more uniformity of colour. In several of these respects my observations have been to some extent misunderstood.

With respect to the Dorking cross, "Y. B. A. Z.," remarks, that "the fifth toe is persistent in a wonderful manner, and is far oftener seen than even the cruel expression," which he agrees with me is often an attendant on Dorking blood. This is quite correct as the general result of an indiscriminate cross—that is, if the cocks and hens of the crossed strain be indifferently bred from, the fifth toe will appear for an almost incredible time; but if a Brahma cockerel be mated with Dorking hens, and the pullets resulting be alone bred from, the Dorking toe will scarcely ever appear, though white legs and cruel faces will, and this is the plan usually followed. Moreover, my remarks applied specially to the examination of an exhibition pen, in which, of course, no five-toed bird would be allowed to appear. I must, therefore, repeat, that in judging of a pen the chief reliable signs of such a cross are, in the case of the hens, a large, coarse, cruel-looking head, white legs, and a comparative absence of "cushion," to which may be occasionally added a reddish tinge and perpendicular markings on the breast. The longer tail which "Y. B. A. Z." also mentions had escaped my observation; but now that he has noticed it, I believe he is quite right on this point, and intend myself, as I would advise others, to keep an eye upon that member for the future.

Regarding vulture hocks, I have already given my views at length, and have just received a note from the most extensive Brahma breeder in England fully agreeing with them, and relating circumstances to show the great injury which is being done by the present rule of judging. I must, however, earnestly protest against the suggestion of "Falcon" and "Y. B. A. Z.," that the birds be trimmed to hide the fault and pass muster. The dubbing of a Game cock has not the slightest analogy, for the simple reason that the practice being universal and entirely irrespective of any particular shape in the member, makes any fault in the comb of a particular strain of no consequence to purchasers or exhibitors, and, in fact, makes the character of the comb altogether immaterial. But the purchaser of a vulture-hocked bird which had been trimmed would be deceived in his purchase, since his produce would be different from what he anticipated and desired. The analogy with the trimming of a Spanish fowl's face may be granted, but as I am one of those who hold that all birds thus treated ought to be disqualified, I shall not be required to argue the question, but I will simply record my emphatic opinion, that its present state, more especially after Mr. Heath's long-continued but ineffectual protests, is alike disgraceful to exhibitors and judges. I happen to know that previously to the Exhibition at Bristol the principal cutler in that town disposed of about half a dozen pairs of small forceps to Spanish fanciers—for what purpose it

is needless to say; but I hope such instruments will never be used generally, save as an admitted infamy upon the Brahma fowls.

Lastly, with regard to colour, I must say a few words in reply to Mr. Lacy. I may be mistaken, but there appears to be a tone of complaint about his letter which I cannot account for, as I have never depreciated either his views or his birds. He seems to imply that if people attend to my remarks (certainly mine have been very lengthy), we shall soon deteriorate Brahmas to "wretched mongrels;" whereas my endeavour has been to point out the evil, not only of crosses from different breeds, but even of differently-coloured strains; and it is somewhat singular that I have a note from the most practical breeder of Brahmas in the three kingdoms, remarking that if my cautions were attended to "we should *not* have so many mongrels as we see now."

Mr. Lacy says I "will have it" there are two schools of colour, and have "been pleased" to attach his name to one of them, and "hinted broadly" that he leans to a brown shade. I hinted at more than two schools; but if Mr. Fowler's letter, compared with his, does not prove that there *are* such two schools, I confess I am hopeless to prove it myself. He admits that he does prefer the brown tint: of what, then, does he complain? for I made no other assertion regarding him, and never implied that his birds were on that account worse than others; and I placed him at the head of the "school" to which he belongs, just as I should have placed some one else, had he, instead of Mr. Lacy, taken in succession the highest honours at our leading show. He appears, in fact, to have misunderstood me as condemning his views, which I assure him I had no thought of doing. I have always regarded this question as one simply of individual preference, just as one man prefers Buff Cochins and another Partridge, and I know that either the brown or the clear colour in Brahmas can be, and has been, produced simply by careful selection. Mr. Lacy seems to forget that when Mr. J. K. Fowler affirmed his favourite brown colour to be introduced "within the last few years by a cross with the Partridge Cochin," I felt compelled to contradict him; as I feel now compelled to question also the statements he has himself made; since he, like Mr. Fowler, is not content with simply defending his own favourite colour, but maintains that the other is "abortive" and wrong. Such a view, from either side, I feel it necessary, in justice to breeders generally, to controvert.

Mr. Lacy argues that the brown is "the correct and only colour" because the down on the chick's back is brown. To refute this it would be sufficient to remark that if the argument be sound, all the down on the body, except the neck and head, ought to be brown also; but as if to show the utter fallacy of such reasoning, it is singular that the heads of many Brahma chicks are darkest and brownest of all, whilst they change afterwards to white in the cocks, and light silvery-grey in the hens.

With regard to Mr. Teebay, I have incidentally recorded my own admiration of the rich colour he used to show, and I am well acquainted with his views upon the subject, but did not feel it right or in good taste to give them, as he is not at present an exhibitor. I can assure Mr. Lacy that these views by no means coincide with his own, and since he has mentioned Mr. Teebay's name, I must remark that the dark colour he showed was a very different tint from that he admires. Not to mention minor points, I will just say, that whilst the pencillings or dark markings themselves in Mr. Lacy's birds are usually very dark brown, in Mr. Teebay's they were a rich black, far denser and more lustrous than any now seen. With respect to Mr. Boyle's exhibiting hens as brown as his own, I, of course, spoke of the general colour each gentleman showed. Pens are sometimes selected to suit the known preference of particular judges; and it is a little singular, that the very last pair of pullets I have seen exhibited by Mr. Lacy were of that identical "abortive" silver-grey colour he professes to condemn. His pullet at Whitehaven was the same.

Finally, in saying that such silver-grey pullets always moult brown, that those who breed them will obtain small size, light breasts, heads and necks white halfway down, and bad feathering—in all these Mr. Lacy is wrong in point of fact. A friend of mine has just purchased from Mr. Boyle, at a high price, a pair of two-year-old hens of good size, heavily feathered, splendidly pencilled, and perfectly and absolutely free from brown. I have now in my own possession a hen of the same age from another yard, which is very nearly free from brown, but splendidly pencilled on the breast, and in size the very largest—I will not say ever bred—but that I ever saw; and when I say she is larger than his own first-prize hens at Birmingham, he will admit she cannot be very "small." And finally, let any one inspect Mr. Ellis's well-known yard and say how far such remarks will apply to it.

I trust I shall not this time be misunderstood, or give offence. My sole object is to contradict the notion that either colour is the "only proper" one for a Brahma, and that the other must be the result of a cross. Both are legitimate, and the result of legitimate and careful selection in breeding. I can admire and see beauty in each, and my opinion is, that the time is nearly come when Brahmas should be again subdivided into three colours, which might be called "Light" (as it is now), "Silver-pencilled," and "Dark or Brown-pencilled." As soon as the number of entries shall justify this, I think there is as much reason for the sub-division as in the case of Cochins, and it would end the present strife about the matter; but meantime I would strongly oppose a pen being either commended or condemned on account of its colour, since one has as much right to his fancy as another. I would only insist that each bird should be uniform in tint, and not as now often seen, contain patches of both. To this end I reiterate my caution, that the indiscriminate crossing of widely different colours will ruin both, and to insure uniformity, that before a cock is purchased the hens of the same yard be found to correspond pretty nearly in colour to those already kept. So will either tint be preserved in harmony and perfection.

With these remarks I conclude my notes on Dark Brahmas, and if I take up the pen again it will be concerning another breed.—Nemo.

PETTED BANTAMS.

My half dozen Bantams have everything their own way. I have given over the garden to them. They are lords and ladies of all they survey there. I cannot have flowers; I cannot have vegetables. To humour my Bantams, I must have nothing but gravel, worms, and insects. If I do not go down every morning and feed them upon the very best shelled wheat they march into the house and peck at my legs. When the snow came on the other day, they left their house, as not being comfortable enough for them, and insisted upon roosting on the backs of my best mahogany chairs in the dining-room.

The noise they make when any female member of the community lays a ridiculous egg, is dreadful. If I go out and beat them, they only make more noise, and the moment my back is turned, the cocks all set up crowing, in token that they have got the best of me.

They are the artfullest cocks and hens I ever knew. They are aware that I am flattered by their flying up on the window-sill, and rapping with their beaks on the glass to call my attention when I am busy writing, and they do it on all occasions, their reward being some chopped meat. They have no objection to their own species, or a handful of canary seed, which they consider a dainty. I even indulge those fowls with black beetles, which I take much trouble to catch for them with elaborate snares in the back kitchen.

What thought and cruel ingenuity do I exercise on behalf of those Bantams! I pour some double stout into a deep basin, I place the basin in the back kitchen, I fix a little wooden ladder to the side of the earthenware wall, and then I enshroud the back kitchen in Cimmerian darkness. The beetles lurking in their holes smell the double stout, which they instinctively know to be Barclay & Perkins' best, they creep out cautiously, ascend the ladders, and reaching the giddy top of the wall make a false step, and fall into the seductive but treacherous abyss. But they are not drowned; such is the refined cruelty of man, that he only puts enough double stout in the abyss to tempt his innocent victims to besottedness. When they recover from the stunning effects of their fall, they think they are in the beetles' heaven, feeding upon the ambrosia of their gods. They wallow in their plentiful cups, and sing roaring songs about beetle love and double stout (they call it "rosy wine," of course), and think it will be ever thus; but artful and cruel man appears in the morning letting in the reflective light, and the unhappy beetles know that they have been deceived. They cry, "Ah! betrayed," and make a rush to scramble up the wall, but are so drunk that they all tumble down again, and their fate is to be eaten alive in a state of intoxication by those bloated Bantams. Never did Roman emperor enjoy such wild, ruthless, extravagant, luxurious saturnalia as those fowls.—*(All the Year Round.)*

LIGURIANS IN IRELAND.

On opening The Journal of Horticulture of April 11th, and running my eye over the columns devoted to bees and bee-keeping, I was much pleased to see the article from "A Devonshire Bee-keeper," on "Propagating Ligurians." I have for some time been looking forward with much interest for the information so fully contained in it, inasmuch as I introduced, last autumn, into my apiary—previously consisting entirely of black colonies—two stocks of the foreigners, obtained from Mr. Woodbury, and I have been most anxious to discover the most likely means of maintaining the strange blood in the purity in which I received it from him.

You may, perhaps, have remembered that in a letter which I addressed to you last autumn on the subject,* I stated that previous to that period I had been deterred from introducing the Ligurians into this neighbourhood, both from the fact of the very high prices demanded for them by some English bee-keepers, and also from their refusing to guarantee their safe arrival in this country. These remarks of mine fortunately met the eye of Mr. Woodbury, who kindly communicated with me on the subject, and made me such satisfactory and fair offers on both the above points, that I was induced at once to accept them, and the result up to this has been most satisfactory to me in every respect.

As the progress of Ligurian bees in this country, during even so short a period, may be a subject of some interest to the Irish readers of your bee-columns, I will mention a few facts connected with them since they came into my possession, premising that almost from the day of their arrival, early in September last, to the present moment, the severity of the autumn, winter, and spring has been unprecedented. And here, at the first start, the opinion of the Baron Von Berlepsch was, in my mind, completely verified—viz., "That the Italian bees are less sensitive to cold than the common kind;" for whereas, amongst my black stocks not one escaped without more or less loss of life, owing to the cold and sudden changes of the weather, not one of the Ligurian bees died from the same causes, and this under most disadvantageous circumstances. When I received them, late in the autumn, they had scarcely a particle of honey, it being essential to their safe transit that they should travel with light combs. Artificial food I of course supplied them with at once and liberally, and the manner in which they stored and appropriated this surprised me, one hive increasing in weight from 16 lbs. nett to 49½ lbs. nett, from the 20th of September to the 9th of November. The other stock, although it did not lay up winter stores so rapidly, is now in quite as prosperous a condition, both having a large and thriving population, and the young bees clearly and beautifully marked in each, testifying to the pureness and fecundity of the queens at their head. So far, then, the prospect of my establishing the Ligurians in this locality looks cheerful enough, were it not for one great drawback which I feared all along, and which the "Devonshire Bee-keeper's" letter almost confirms —viz., that my apiary is almost entirely unprovided with bar and frame hives, only one of my black colonies being supplied with that necessary (as it appears from his letter) article for propagation. When commencing bee-keeping, I started on the wise, as I supposed, principle of "learning to creep before attempting to walk," so I invested entirely in plain Scotch hives. Under these unfavourable circumstances I can only ask, "What am I to do?" feeling sure that I shall obtain from you advice as to the best course of action under the circumstances.

What is the proper time to commence forming "nuclei?"

Before concluding my desultory remarks on the Ligurians here, I must add, how much I was struck by the wonderful advantages of the bar and frame hives in transporting bees, both as regards safety of the combs and perfect ventilation. The manner in which Mr. Woodbury secured them was to me a marvel of skill and ingenuity, and I believe they might have travelled without injury to the end of the world.

As the season advances, if it should be a matter of any interest, I shall be happy to report the progress of my new friends and my attempts to increase them. Curious to say, after such a severe winter not one of my stocks did better than one in a glass observatory hive of my own construction. The hive which was single glass, I placed in a box, with an interval of half an inch carefully packed with tow and wool, and hardly a bee died in it.—Squib, *Co. Kildare.*

[You will do well to transfer some of the strongest of your black colonies into frame hives during the present month, or as soon as they become populous. You may find hints on this subject which will be of service to you in Nos. 75 and 280 of our New Series, but the process is briefly this:—During the forenoon of a fine day drive all the bees into an empty hive and put them on their accustomed stand. Take their original hive in-doors, and cut out all the combs whole. Fit these into frames, and support them therein by strips of wood three-eighths of an inch wide and one-sixteenth thick, tacked at the top and bottom, two on each side of every comb, and by zinc clips when necessary. Thick combs must be pared down, but take care that the cells on either side are left of equal length; also that the "partition wall" is in the centre of each bar. Crooked combs should be set straight, and if not sufficiently pliable to permit of this being done may be slightly warmed before the fire. It will be found convenient to remove the projecting Woodbury rib from the bars, and the bees will attach the combs to them with greater facility if their under surface be coated with melted wax. Having completed the job, and arranged the combs in their new apartment in the same order as that which they occupied in their old one, deepen the hive by the addition, on the top, of another, from which the frames and crown and floor-boards have been removed; set it on the old stand, and knock out the cluster of bees into the upper hive on the top of the frames of the lower one, putting on the crown-board immediately. Next morning take away the inserted hive, and the day after that remove the supports from all the combs which the bees have fixed. If any are not secured, their supports may be left until they are fastened.

The formation of nuclei may commence as soon as any of your stocks are strong enough, and possess a tolerable quantity of drone-brood.]

* This letter appeared in No. 279 of our New Series.—Eds.

DRONE BROOD.

I examined a Woodbury hive to-day (April 23rd), for the purpose of excising royal cells. I only found one, apparently an old one, empty (the stock was a swarm of last year); but in the middle of one comb I found about thirty large cells covered with semicircular domes of a light brown colour; they stood out very prominently and conspicuously in the combs, and each contained a large white grub. Although I have busied myself much with bees for a few years, I have not had the means of looking inside a hive till lately, and am ignorant of the various appearances of drone and worker brood, &c. I conclude the cells referred to contain drone brood. Had they been formed the other way up—*i.e.*, vertically—and on the edge of the combs I should have concluded they were royal cells. I may inform you that the stock, though a swarm of last year, gave me 18 lbs. of honey, is now very strong (it has been fed), and has a splendid queen, and plenty of sealed honeycomb. If the above are drone brood, why so few of them? I shall be very glad of more information about the method of emptying combs given in page 288.—C. C. E.

[It is too early to look for royal cells, especially in so backward a season as the present. The large cells with semicircular domes contained drone brood, and that in an advanced stage, owing to these few cells being placed in the centre of the comb. The number was doubtless limited by the number of drone cells, but had you carefully scrutinised the interior of such large cells as exist nearer the edges of the combs, you would most probably have found them also tenanted by eggs and larvæ in a less advanced state. We will endeavour, whenever we have the opportunity, to obtain further information respecting the German centrifugal machine for extracting honey from the combs.]

ECONOMY IN COAL.

I suppose every one wishes to be economical in housekeeping; the majority from necessity, the minority, I hope from a wish to make their charity purses larger. The best rule is—"Economy practise, but do not be mean."

A little more than a year ago, I met, when away from home, a gentleman who was full, very full, of a new plan, which if carried out would make his coal bill smaller, smaller by half, and yet his fires were to be as large and as warming as ever. I smiled incredulously, thinking him a most enthusiastic man. He said, "Now here's my plan: Send for your blacksmith, set him to take the width and length of your grate, and floor it with a piece of iron half an inch thick." "What!" said I,

"so that no cinders, and not even any ashes can fall through?" "Yes, exactly." "But how can the fire draw up? and how dull and dusty your fire must look." "Nothing of the kind, I assure you; only try, and then you will see." But I did not try, and being very much attached to old ways, I poked my fire all the more, and rattled the dust out vigorously, thinking, "Whoever will may have a dull fire, but I will not."

Nearly a year passed, and I heard no more of solid-floored grates, when the delusion, so I deemed it, reached my own neighbourhood. Being assured by experienced persons of the economy and convenieuce of the new plan, I determined to try it, but only in my study. A son of Vulcan, well experienced in the matter, came and measured my grate, and speedily, instead of open ironwork, it was floored with a solid slab of iron, so that not a grain of dust could drop through. Next morning I was surprised to see the fire burning very brightly, and to have no complaint about the difficulty of lighting it. I was also surprised to find how seldom I had to get up and pnt on fresh coals. After a week's experience we were all satisfied of the comfort and economy of the new scheme. Gradually I have extended the plan throughout the whole house; first in my study, then to the nursery, then to the dining and drawing-rooms, and, lastly, to the kitchen. Our experience reaches over two months, and we would on no account return to the old system. An artisan's wife, a careful body, weighed her coal, first while following the old plan, then after adopting the new one, and finds that by the latter she saved just one-third.

I like this flooring the grate with solid iron for the following reasons:—First, the fire wants making up only three times a-day; then there is a total consumptiou of coal, or nearly so, as there are, or ought to be, uo cinders, except those left in the grate, and the larger pieces come in nicely for lighting the fire in the morning. Then one's fire is not always, as the maids say, "dropping out," but will keep in for hours, and if once "low," draws up again very quickly. Also, of this I am sure, the amount of heat is greater than obtained by the old plan. The servants make no objection, only they are apt to neglect what I insist on—viz., throwing up every cinder that comes through the front bars. The dust accumulating at the lowest bar must be geutly removed by the poker. In large towns, where I believe riddliug of cinders is never practised, the saving would be greater than in the country, for, of course, the loss of cinders ought to be borne in miud. I feel so certain of the economy of this plan, that I have had the grates of some of my poorest parishioners altered for them.

I send this accouut to "our Journal," as many careful housekeepers who may not have heard of this plan, will be glad to have a hint in economy, and, iudeed, the saving of coal is a national duty, inasmuch as it is believed by scientific men who have examined into the matter, that our mines will become exhausted in a certain number of years.—Wiltshire Rector.

[We believe that this plan is worthy of adoption, and we found our opinion not only upon our correspondent's experience, but upon that of Serjeant Warren, who, we believe, was the originator of the plan. This well-known author is Recorder of Hull, and at a dinner held in that good old port in the Jauuary of the present year, he publicly advocated this mode of economising fuel. His address was excellent, and with equal excellence it has been versified by a clever physiciau as follows:—

"Mr. Mayor,
Corporation, and Town,
To all, with a fervour sincere,
I wish every blessing may crown
A prosperous happy New Year.

Permit me some facts to instil
Io your minds, on a practical question;
That may show you at least my good will
By a kindly and useful suggestion.

Do you wish to obtain without waste
Due heat from the coal you have paid for;
Or prefer it to burn out in haste,
Not working the good it was made for?

Do you wish—I may ask in a word—
To save your domestics some trouble;
To lessen your coal bills a third:
And the warmth of your hearth to make double?

If you do, to my guidance attend:
For some seven years, more or less,
I have tested, with many a friend,
A plan with unbroken success.

By me no invention is claimed.
I read the idea in *The Builder*:
And the paragraph ought to be framed
By some eminent carver and gilder.

If you look how your grates have been made,
You'll see that the blacksmiths—Od rot 'em!
Have forged, for to forge is their trade,
A layer of bars at the bottom.

Now, having been called to the Bar,
I know where the bars ought to be;
And those blacksmiths—whoever they are—
Should be brought up, as forgers, to me.

For observe how the coal must be placed
'Twixt a couple of draughts to consome:
Which causes your fuel to waste,
And the heat to grow less in your room.

Now when I first reached my hotel
On Wednesday afternoon last,
The fire was made—and made well—
Yet I shivered at many a blast.

So I sent for my landlord—(good man,
I knew I should not overtask him),
And besought him to follow my plan.
He has done so, with what result?
Ask him.

Since my fire was made up at ten
I've enjoyed all the warmth I desire;
And at five I'm the warmest of men.
Without thrusting my nose in the fire.

Not an ounce of additional coal
Has been needed, nor watching, nor stoker;
Save to break an occasional hole,
Or to press down the top, with the poker.

Now, how was all this brought about?
I will tell you,—as blacksmiths environ
Your excellent town, call one out
With a small piece of common sheet iron.

He will speedily cut you a plate
(Any pattern will do on a pinch),
It should just fit the base of your grate,
With a thickness one-sixth of an inch.

Let your maid in the usual style
Lay your fire, and have it ignited,
Leave the lowest bar open awhile,
And you'll be both amazed and delighted.

For as soon as the fire burns through
The coals, with warm glow and bright flashes,
The heat will not fly up the flue,
Nor your hearth be encumbered with ashes.

In my breakfast-room grate I began,
In my dining-room next, and my kitchen;
Then everywhere followed the plan
With success that was really bewitching.

In my residence (likewise) official:
And, my fire once lit, I may say
That attention the most superficial
Will last for the whole of the day.

Now, pray do not smile at my plan,
Nor think my suggestion is dull;
For I'm anxious to do what I can
For the good of the old town of Hull.

Try it fairly, I beg of you all,
Ere your coal stores unduly decrease:
Begin with our noble Town Hall,
And the Town Clerk, and Clerk of the Peace.

I don't mind defraying the cost
If you find that experiment fail;
And pray ask my excellent host,
Mr. Baiston, to tell you his tale.

As I write for the good of the town,
For householders mighty or small,
Pray publish the facts I note down
For the general profit of all.

For the cold winter winds bite severely;
And coal is expensive to order:
I remain, my dear Mayor, most sincerely—Yours,
SAMUEL WARREN,
Recorder.

P.S.—If this plan do not answer—
For chimneys may obstinate be—
Just draw out the plate—which you can, Sir,
For it isn't a fixture, you see.

Approving the scheme and its fitness,
And finding a trial work well—
Mr. Bainton declares we shall witness
Its merits throughout his hotel.

On reading this amiable letter,
And the plan which its pages unfold,
I ask, Could there well be a better
Suggestion to keep out the cold?

Hurrah! for a true friend in season,
His name shall be hailed with a cheer,
He may claim the good wishes—with reason—
Of ten times "Ten Thousand a-Year."

"Now and then" the idea which he mentions
Will be known as his "New Work, with Plates."
And the fruit of his kindly intentions
Will be famed as the Warren-ted Grates.

All hail! then, warm hearths and bright fires.
Henceforth from chill currents set free,
Till ice-crowned old winter retires,
And we welcome the "Lily and Bee."]

OUR LETTER BOX.

Preserving Eggs (*E. S.*).—We answered a similar query in our last number, page 304.

Peacock's Feathers with a Film of Skin (*A. B.*).—Your bird is out of health, and probably feverish. The feather forms properly but dries up. Give no whole corn. Feed on meal slaked with cold water, and let him have plenty of lettuce. It is an admirable poultry medicine at this time of year. There is no objection to splitting and removing the filmy case that holds the feather.

Brahma Pootra Chickens Losing their Feathers (*W. F.*).—It is often the fact that chickens appear more naked when their feathers are coming than they did while only partially covered with down. The wing feathers grow faster than the others, and throw them into the shade, and many parts of their bodies are always naked till perfectly fledged. Many of our own are in this predicament; but we do not think it worth notice, as they are evidently in perfect health. We like to let well alone.

Chickens' Legs Swollen (*North*).—We imagine, from your description, that the hens have left the chickens for some time. If so, that will partially account for their illness and falling off. They lack the covering and warmth at night, or it may be, you allow the hens to roam at liberty, and they drag the chickens through the high wet grass. It is not high for the hens, but it is for the chickens. We were watching our Brahmas running in the grass a day or two age, and seeing the treatment our hayricks have received during the cruel winter, we were delighted to find the chickens' legs were not visible. Fancy chickens seven weeks old a hundred yards from home, and overtaken by one of the pelting storms we have had. If they were lucky enough to reach home they would hardly recover; but whether with or without the hen, they cannot do well if kept on boards. That fact is enough to account for crampy and swollen legs. You do not, however, allow them sufficient space; 12 feet square might have done well some time since, but they have grown in size and requirements, and want elbow-room Choose a dry, dusty, and sheltered spot. If you have no other house to give them, take an old china crate, cover it carefully at the top and on three and a half sides. See that inside it be full of dust and thoroughly free from draughts, and at night put your chickens in it. Place food and water close at hand for them to find it in the morning. You will save many by doing this, and another year you will save more by putting the hen and chickens out of doors, but keeping the former under the rip.

Pine Sawdust for Egg-packing (*Idem*).—We should prefer it to bran for packing eggs; but for a journey by railroad, even of four hundred miles, we do not think it would injure them for hatching.

City Columbarian Society (*B. C. J.*).—The Secretary's address is, Mr. J. Ford, Stamford Cottage, Summer Hill Road, West Green, Tottenhnm, N.

Honey Candying in Combs—Artificial Swarms (*A Constant Reader*).—An extremely low temperature within the hive is the cause of honey candying in the combs. Full instructions for making artificial swarms with common hives were given by Mr. Woodbury in No. 161 of our New Series, and a supplementary article from his pen on the same subject will be found in No. 217. His instructions were also epitomised by us in reply to a correspondent in No. 271.

WEEKLY CALENDAR.

15	W	Meeting of Society of Arts, 8 P.M.	65.1	41.9	54 5	15	11 4	42 7	26 4	5 3	11	3 51	135

From observations taken near London during the last forty years, the average day temperature of the week is 63.0°; and its night temperature 40.4°. The greatest heat was 86°, on the 15th, 1833; and the lowest cold 25°, on the 15th, 1850. The greatest fall of rain was 1.14 inch.

CRINOLINE.

IN the course of the last year I observed in your Journal —I beg pardon, "our Journal" — an advertisement several times repeated, and headed, "The momentous question crinoline;" and once, "The great crinoline question solved." I found no solution of the momentous question attempted, either in that advertisement or in any subsequent one; but it naturally excited a spirit of inquiry, and such questions as the following arose in the minds of thoughtful readers: "How came such an advertisement to be sent to a Journal of Horticulture?" "Is there any occult or recondite connection between crinoline and gardening?" To whom is the great and momentous question addressed—to ladies only, to horticulturists, or to whom?" "What *is* the great and momentous question concerning crinoline?" and "how is it to be solved?" After ruminating upon these several queries, and turning them well over in my mind, I at length obtained, as I apprehend, a clue to the profound mystery.

Crinoline *has* something to do, or to *un*do with horticulture, and the great question for solution is, Whether it is to be included among "Our Garden Friends or Foes?" I turned to the interesting volume under this title by the Rev. J. G. Wood; there was no mention of crinoline in the index, nor did I find it included among the various species of *lady*-bird, all of whom he decidedly reckons as garden friends; so I conclude that he was too wise to venture upon so delicate as well as momentous a question, and prudence, therefore, dictates that I should confine myself to supplying the reader with materials for reflection, without pronouncing any verdict, and let him arrive at the solution himself by the deductive or inductive process, whichever he may prefer.

I fear that I must myself be of a peculiarly sensitive temperament when I avow that the very sight of crinoline among my flower-beds, except it be restricted within the very smallest dimensions, does communicate to me an indescribable sort of electric shock. It may be that in certain crinolined petticoats there is some mixture of copper and zinc wire which transforms them into portable galvanic batteries, only I am at a loss in that case to know where the acids are to come from which evolve the electricity, when those who wear those articles abound only in sweets: therefore I must abandon that hypothesis, and come to the conclusion that there is a certain condition of the nervous system superinduced in amateur horticulturists, like myself, at the sight of these appendages; for I have observed that those who have no real taste for the art can follow in the wake of crinoline, and behold with stoical indifference the ravages made by it; whilst I have been like a toad under a harrow at every step which it has made, my *harrowed* feelings rendered the more painful because I have had to endure my agony in silence.

"Ravages!" I think I hear some fair one whilst perusing these lines exclaim at that word ravages, "What ravages can this writer mean?" I nevertheless must in sober seriousness repeat the word ravages. Yes, I have witnessed many a blooming flower laid low in the borders by the mere fact of one of these mowing machines being conducted along its boundary, one-third at least of the hoop reaching into the bed and ruthlessly sweeping down whatsoever opposed its progress, the fair one who conducted the machine talking, smiling, laughing, heedless of the devastation she was committing! But what is even this compared with a party of three or four visiting your garden for the express purpose of admiring your pets? (very flattering!), who enter into the mazes of your parterres, the patterns being formed by narrow alleys of green turf, and follow each other singly, like wild fowl, through all the intricacies and involutions of the flowery labyrinth —the skirts of each one far overlapping the beds on both sides—looking before and on each side of them as they thread their course, talking and exclaiming, "Oh! how lovely!" or, "How beautiful!" or, "Dear, how very pretty!" (poor comfort!), but never looking behind them at the way in which they are sweeping down, as with the besom of destruction, Pelargoniums, Calceolarias, Verbenas, Petunias, and what not. A tornado, a typhoon, or a cyclone could do little worse.

Before the bedding season commences you are liable in the parterres to the same irruptions of the Vandal crinoline; when the beds are full of bulbs in bloom, the same "fell swoop" passes over Tulips, Anemones, and the like; you may even hear the snap of your Van Thols and Hyacinths, and plants of succulent or brittle stem, and see them lie decapitated before you. I confess, that pleased as I am to greet the joyous faces of such visitors when entering the garden, I feel relieved when I see them withdraw from it. They remind me in such a case of a saying of old Berridge, a facetious but truly excellent divine, that the visit of a friend sometimes afforded him two sources of pleasure. "I am glad," quoth he, "when my friend *comes*, and I am glad when my friend *goes*."

I say nothing of the conservatory, because I do not myself possess one worthy of being so called. The flowering plants in my humble greenhouse are not placed within the range of these formidable weapons; but I have seen conservatories on the premises of friends in which the alleys have been but narrow, or the whole area too much crowded with plants, through which, as armour-plated ladies have passed along, they have brushed off the bloom from those plants which were on the floor, to the no small discomfit of the gardener. I have heard of a conservatory in the vicinity of New York over the entrance of which was a notice—"Ladies not admitted except in bloomers."

Well, a good moral lesson may, after all, be derived from these trifling mortifications incident to human civilisation, if we have but grace to receive it. They teach us the vanity

of all that is worldly, and admonish us not to place our affections inordinately upon any pursuit or pleasure however lawful and even elevating it may be in itself. I remember that the poet Young in one of his satires (I have not the book by me to refer to), paints an amateur florist at a period when the passion for Tulips was a sort of monomania, and describes him as standing and doting over his "Paul Diack," a Dutch variety which reached a fabulous price, and then exclaims—

"O solid bliss! which nothing *can* destroy,
Except—a cat, bird, snail, or idle boy!"

Had the poet lived in our day he might have added a third line—

"Or crinoline, the bane of florists' joy!"

There is another department of the garden which invites a passing notice of crinoline, but in this instance it is doubtful whether it is to be considered as friend or foe. Mr. Wood perhaps would place it among the neutrals. I refer to that portion of the lawn now generally set apart for the royal and almost universal game of croquet. Crinoline in this instance, often most inconveniently, displaces the balls for the players on the one side, and as conveniently for those of its own side. It cannot for one moment be supposed that there is any conscious unfairness in such movements of the balls, but it is sometimes extraordinary, notwithstanding our entire confidence in the honesty of the sex, how a ball which is a long distance from its hoop, and in a wrong direction, after having been covered by the crinoline cup, is found by some magic or *leger de jupe* in position, certainly reminding one of the inexplicable mysteries of the thimble-rig! On one occasion, indeed, when I stood amazed at the clever transposition of a ball, the ingenious *artiste* made the avowal with ingenuous frankness and most bewitching smile, "I do dearly love a little bit of cheating!" but I relate this in strictest confidence as a secret never to be divulged by the reader. I draw no general conclusions from the fact: I leave the question *in mediis*, giving to crinoline the full benefit of the doubt.

And now, to bring this "momentous" subject to a conclusion, let me ask, How has crinoline ever come to be patronised? The chief art in female dress, one would suppose, would be to improve or set-off the beauty and symmetry of the wearer, but the reverse is the case in regard to crinoline. It may set-off the silks of the mercer, or display the pattern of a shawl, but assuredly it does not improve "the human form divine." I suspect that the person who first introduced such a preposterous fashion must have had some deformity to conceal, and she must have possessed no little boldness or courage to have ventured out of doors with such a skirt. Horace thought that the man's nerves must have been bound with brass who first ventured to navigate the ocean: there is no poetry in the case of the female who first steered her course through the streets of London encircled with crinoline; she was literally surrounded with hoops of metal of some kind or other. Query, brass?

One might solve this inquiry better if the *unde derivatur* of crinoline were clear. Whence does it derive its name? It may have been from the Latin *crinalis*, in which case we must conclude that the first petticoat of the kind was made of horsehair, or hair of some sort; but there are two little Greek words which come as near to the mark, and have also an affinity with horticulture—viz., *krinon* or *crinon*, a Lily, and *linon*, Flax; whence, possibly, *crino-lin*, a flaxen Lily—a mammoth Lily truly! The admired Japanese auratum, large as it is, dwarfs into insignificance in the comparison. Unfortunately, however, for this hypothesis, the Lily is inverted in the petticoat, resembling rather a monster Campanula or *Bell*-flower, and reminding one more of Big Ben of Westminster. There is, indeed, another use of the word *linon* in the Greek: it signifies a fisherman's net and an angler's line. Ah! can it be possible that crinoline was first adopted by an angler, or fisher of men, in order to render "the take" more destructive? I dare not further pursue this branch of the inquiry lest I myself get fishing in troubled waters; so I leave the whole question as among the doubtfuls—*in dubiis*, as the schoolmen say.

Let it not be supposed, however, that my quarrel is with those who wear the crinoline; it is with the article they wear; for what, indeed, would our gardens be without them? As a desolate wilderness, and our flowers would all

"blush unseen,
"And waste their sweetness on the desert air."

They give life and animation to the scene, and a well-selected bouquet of fair ones will at any time eclipse the most exquisite of flowers, and cause their lustre to pale and disappear like stars before the risen sun. I simply sign myself therefore—ANTI-CRINOLINE.

BLUE-FLOWERED BEDDING PLANTS.

IT is a very common remark among flower gardeners, both amateur and professional, that we have only one really good blue-flowered bedding plant—namely, Lobelia erinus speciosa, with its varieties. Now, to say the least of it, this assertion is very unfair, as by implication it reflects rather seriously upon the good name and character of more than one very respectable blue flower. The Lobelia certainly is the most serviceable, because the most manageable, of any blue-flowered bedders which we as yet possess, and for certain situations could hardly be surpassed by any the most visionary could imagine. In scroll or chain borders, associated with Cerastium and other low-growing plants, nothing can be better; but I have seen beds 8 or 10 feet in diameter massed with it entirely, with a view to complete some complicated combination of colours which nobody but the designer himself could detect; and however well such beds may look from a bird's-eye point of view, to ordinary earth-walking mortals like myself they appear decidedly weedy.

Delphinium formosum, while admired by everybody, is but little used as a bedder, though why this should be the case is not very evident; as regards colour, it is in no way inferior to Salvia patens, while in form, habit, and storm-enduring capabilities, it is beyond all doubt greatly its superior. For mixing in large informal beds, as centres for such, or as a second back row in ribbon-borders, it is very effective; in fact, by a moderate amount of pegging down it may be made available for nearly every situation in any design not absolutely arabesque. The sole blot in its character is, that between the first and second flowering there intervenes a period of six weeks or two months, according to the season; therefore to obtain a succession of flower it is necessary to plant doubly thick, and retard every alternate plant by cutting it back a week or so before the time it would be in flower. This naturally induces an earlier second growth, which will come into bloom in good time to take the place of the plants not subjected to the same treatment.

I have thus grown this Delphinium with varied success for the last three years, keeping the plants in reserve-beds over winter, and transplanting them about the end of April, by which time the flower-stems are well developed, and the operation serves the purpose of retarding them considerably, especially if a good part of the roots are cut off in the process.

I am now inclined to think that the same result might be better effected by using only seedlings of the preceding year. By raising them from two or more distinct sowings there is little doubt that a succession of superb blue spikes might be obtained from June to November, and I think it would be interesting to many readers of THE JOURNAL OF HORTICULTURE if some correspondent would show a little light on the subject.

Another blue bedder, the merits of which I think are but scantily appreciated, is the beautiful little Cape Aster (Agathæa cælestis); its tidy habit, dark green foliage, and sky-blue star-like flowers, all indicate it as a plant almost worthy of its name—certainly of more patronage than it has yet received.—AYLSHIRE GARDENER.

LAYERING VINES.

LAST year Mr. Thomson, writing on the coil system of planting Vines, spoke very strongly against Mr. Rivers's plan of layering any part of the old stems, and after describing his experience on this head, he said, "I prefer shaking out the roots entirely, and not layering a morsel of the stem." On page 28 of Mr. Thomson's book on "The Vine," I find him describing a mode of successful planting, thus—"I then spread out the roots, &c., laying three joints of the wood, as well as the roots, in the soil, making an incision with the knife below each bud to induce the emission of the roots," &c.

There seems to be some contradiction here; and it so happens that I have, and I now fear somewhat unfortunately, followed out the last directions of Mr. Thomson with a new house I have just planted. If the first plan—viz., that of 1866, is the right one, I am in fear for the success of my Vines, which I cannot well afford to lose. I felt doubtful about the nicking process at the time, but thought I could not be wrong

to do what Mr. Thomson recommends. I should be glad to hear how he explains this apparent contradiction.—Vitis, *Lincoln.*

[In reply to your correspondent "Vitis," allow me to say that it was my brother and not I who had a controversy with Mr. Rivers about layering the stems of Vines in the soil at planting.

I am still of opinion, founding that opinion on extensive experience, that my recommendation at page 28, as quoted by "Vitis," is sound. If he will turn to "Experiments with Vines," he will observe that I planted a house of Muscats at Wrotham Park, in 1847, exactly as he has done his, following my advice; and if he will address a note to Mr. Edlington, Wrotham Park, Barnet, who has the management of these same Vines at this date, he will learn that more healthy, fruitful Vines are rarely to be met with; and at a distance of time of twenty years, this is surely satisfactory evidence in favour of the system of planting "Vitis" has adopted on my recommendation. I can give him scores of examples of the same sort if he require them.—Wm. Thomson, *Dalkeith Park.*]

THE ORIGIN OF COLOUR IN TRICOLOR PELARGONIUMS.

I have read with great interest the very able remarks of your correspondent "M.," at page 291, and perhaps you will kindly allow me to thank him for his very courteous criticism of my letter on the same subject in your impression of April 18th.

Science, I am now aware, did not justify me in supposing that brown and yellow would produce red; but, paradoxical as it may appear to be, ignorance in this particular instance proved an advantage, as acting on this erroneous conviction, and aided by some principle inherent in the leaf, but of the nature of which and properties we are at present ignorant, the desired effect has been produced.

With regard to the Golden Tricolor Pelargonium mentioned by "M." as having been raised by Mr. Hally, of Blackheath, some fifteen or twenty years ago, and named Rainbow, I can only say that I never saw it, and never heard of it before; and it certainly seems strange that this variety should have remained in obscurity so long. Pelargonium Mrs. Pollock was raised, I think, in the year 1858, and when it was sent out two or three years later, some one in writing upon the subject subsequently, said, "that the advent of Mrs. Pollock literally took the horticultural world as it were by storm." That it created a sensation is not to be denied, and it is really difficult to believe that a variety quite equal to it, according to "M.," should have been flourishing for so many years before that time at Deptford or Blackheath, and yet for so very few people to have known of its existence. I most sincerely trust, however, that "M." will set the matter at rest by exhibiting a plant of this variety at the exhibition of Tricolor Pelargoniums to be held at Kensington on the 21st of this month.

I cannot at present refer to Mr. Pearson's letter, but I think that he did not exactly say what "M." says he did—viz., "that no single plant of this class of Pelargoniums was antecedent to Mrs. Pollock." I think he said, "that none worth growing existed previous to the introduction of this variety."

"M." is decidedly in error with regard to the origin of Italia Unita. That variety was produced between a dark-zoned seedling of my own, and a Silver Tricolor sort named Rainbow also raised by myself. Rainbow was produced between Cerise Unique and Attraction, and both the last-named varieties were, I believe, raised by Mr. Kinghorn; and the last-named (Attraction) was, I believe, the first Silver Tricolor Pelargonium produced. I have never once used Burning Bush for the purpose of breeding. I am inclined to think that there exist physiological reasons for doubting the fact of a golden-margined variety producing a silver-margined sport, but possibly I may be wrong in this supposition; but at all events the fact requires confirmation. In the *Gardeners' Chronicle* of last September I gave the pedigree of Pelargonium Mrs. Pollock, which your correspondent "M." and other readers may not have seen, so I will quote from a copy of my letter for their information:—"The seed-bearing parent of Mrs. Pollock was a variety called Emperor of the French, and the pollen parent Gold Pheasant. The seed parent of Gold Pheasant was also Emperor of the French, and the pollen parent Golden Tom Thumb. The seed parent of Golden Tom Thumb was an old variety called Cottage Maid, and the pollen parent Golden Chain." The seed parent of Emperor of the French was Cerise Unique, and the pollen parent was Attraction. The result of this cross was three distinct varieties produced on one plant—viz., Emperor of the French, Empress of the French (a marbled-stemmed variety like Cerise Unique), and the Silver Tricolor variety called Rainbow.—P. Grieve.

The fact of being a near neighbour of Mr. Grieve for the last dozen years enables me to write with some authority on the subject. There can be no question that to him belongs the rare merit of originating most of the best varieties, and also of having anticipated their production. His object from the first, as frequently explained to myself and other friends, was twofold—to enlarge the size, and impart greater stamina to Golden Chain, and by an intermixture of blood between Golden Chain and the Horseshoe varieties, to obtain new combinations of colour. The appearance of Flower of the Day, and other Silver-leaved sorts, turned his attention to the subject. By crossing these with Zonals, and obtaining a pink zone, he was easily led, as described by himself at page 275, to believe in the possibility of producing Golden Tricolors; to secure this object it seemed only necessary to pour golden instead silver blood into the dark-leaved Zonals.

Such was Mr. Grieve's theory years ago, and I am not aware that he has ever swerved a hair's breadth from it since. The results are before the world in such splendid varieties as Mrs. Pollock, Lucy Grieve, Lady Cullum, Mrs. Grieve, Mrs. Beuyon, &c. It matters little to the establishment of the point of designed production, whether Mr. Grieve's views upon the effect of mixing certain colours are scientifically correct or not. It is sufficient here to prove that he had a theory, that that theory, right or wrong, aimed at a definite object—the production of Golden Tricolors, and that his practice compassed that object. Beginning with Golden Chain and the best Zonal at command, and then choosing the pollen of his own best seedlings as the magic brush with which he has painted, he has succeeded in originating and fixing more and finer colours on, in, or about Pelargonium leaves than any other grower of whom we have heard.

The difficulty of fixing the whereabouts of the colours leads me to state that I think both "M." and Mr. Grieve treat the general question of colour rather too mechanically. They assume throughout that it is a substance, thus taking it for granted that it is a quality inherent in bodies. This much cannot be said to have been proven. Colour may be an optical phenomenon—a matter entirely between the light of the sun, a given surface, and the eye of the beholder—a question of absorption, reflection, angles, or speed of different rays of light, and not one of physical structure.

Or, assuming that colour is a substance, it is obvious that it cannot be laid on living surfaces, such as leaves or flowers, as the artist spreads his colours on his palette, or the experimentalist evolves different hues, by placing the primary colours in certain relationships to each other. We must not overlook the disturbing power of vitality. Life is a fortress too high for the dwarfed ladders of our knowledge to scale, too strong for our powers to carry by assault. We only know that it is full of beauty, power, and mystery, and that it is undermined in all directions by disturbing forces that baffle our wisdom and defy our strength. Two of these forces that probably exert as great, or a greater, influence on colour than any mere mechanical depositions of tissue, coloured or otherwise, are chemical action and vital force.

Each plant is a miniature laboratory; by the intermixture of salts, acids, and alkalies, plants probably manufacture their own paint, as well as elaborate their inward secretions. Light handles the brush, but the paint, if produced at all, is most likely home-made within the plant itself. A familiar instance of this chemical paint-making is seen in the application of alum or steel filings to Hydrangeas. It changes the colour of the flowers from pink to blue. Doubtless this power which comes to the surface in this instance, is a powerful though hidden colourist in myriads of other cases.

Then there is the vital force. Its power, like its Author, seems omnipotent. Perhaps it does all the colouring. How else shall we account for the capriciousness of its distribution, or the regularity of its arrangement, or the sharpness of its limits? Adverting only to the last, what peculiarity of structure or chemical action will explain our inability to originate a blue Rose or Dahlia? Or if it be contended that blue being a primary colour, no combination of other colours can produce it, and therefore we fail, then I fall back upon the extraordinary fact adverted to by Mr. Grieve—that he has

hitherto been unable to obtain a cross between two such closely related classes as the Golden and Silver Tricolor Pelargoniums. Whence this repugnance to intermarry? The vegetable kingdom abounds with such examples, and it seems well nigh impossible to account for them unless on the hypothesis that vegetable like animal life is endowed with some magic power analogous to our sympathies and antipathies. On such a vitally important matter as the perpetuation of itself in an altered form, condition, or colour, the *will* of the plant, as imprinted on the laws of its life, has to be consulted and obeyed. The vital force resents violence, and limits the operations of the hybridist by the strong arm of unyielding law—keeping him inside its own closely defined lines of consanguinity or affinity. If such a power is exercised—and no one can prove that it is not—on the origin of species and varieties, it is probably also put forth in the secretion, rejection, or arrangement of colouring matter, supposing colour to be a quality of bodies, or in the selection or rejection of particular rays of light presuming that it is not. In either case it seems almost impossible to conceive the colouring being so exquisitely laid on, or made to appear as if it were, without the presiding skill and matchless energy of the vital force.

Mechanical colourists may reply that structure is also the result of the same energy, and that in contending that colour is chiefly dependent on the disposition of separate layers of matter, they neither ignore its existence nor seek to curtail its power. But there is a wide distinction between growth and colour, else the two would probably not only be co-extensive, which they may be said to be now, but all colours would probably be alike wherever there was identity of structure.

Neither is it necessary to enlarge upon the influence of light upon colour. This is well known, and is accepted as the basis of all true theories upon the subject. I believe, however, that just as the sun's rays in their entirety produce white or colourless light, so this light in an unbroken state naturally produces green colour. Resolve the sun's rays into their original elements by passing them through natural or artificial prisms, and we have the glorious hues of the rainbow. Break up light by the mechanical media, chemical power, or vital force of plants, or endow them with a natural power of selection of sunbeams, and the result probably is variegation. And just as the rainbow is not the product of a coat of paint on the sky, so brilliant hues in plants may not originate in a layer of colour on their leaves. Both alike may arise from the disintegration of light, if I may so express it, and not from the introduction of new matter. So far I agree with "M.," that variegation is not the addition of a new colour, but the subtraction or elimination of more or less of other tints. It is not a question of putting anything fresh in, but of bringing something old out. It removes, it may be, a layer of matter like a pigment from an artist's colour-box, or takes out part of a sunbeam from its shining sheath, and the result in either case would probably be identical—the exhibition of a new colour. The pencil of the hybridist, then, is less the brush of the artist than of the eliminor; his mission is the removal of overlying matter, so that the great primary colours, red, yellow, and blue of the grand old master Nature may be brought out in their distinctive clearness. Red and yellow have already been separated; can blue also be made to stand alone? It is probable that it may. Earnest efforts are being put forth in this direction, and when the theory of elimination is better understood, greater success will doubtless attend them.

Nature seems to favour the hybridist. New colours once produced have a tendency not only to perpetuate but to intensify themselves. Probably this arises from the fact that not only are different rays of light endowed with distinct functions, but their energy is strongly influenced by the colour of their transmitting media. By such means the chemical power of the sun is probably exerted on behalf of the hybridiser. It works to remove more of the green and expose brighter colours, to break up Nature's mixture, and resolve it into its original elments. It is a matter of actual fact that Mr. Grieve has gone on from good to better, until he has approached towards perfection in yellows and reds.

Beginning with Golden Chain, the following varieties show the progressive development of colour like the ascending steps of a ladder—Gold Pheasant, Mrs. Pollock, Lucy Grieve, Lady Cullum, and Mrs. Grieve, the best of all. Neither does he yet despair of a blue. For this, however, I believe he will have to appeal more to the vital principle and the distintegration or separation theory, and less to the mechanical induction of colour. Otherwise I, who have hitherto contented myself with carefully noting, occasionally chronicling, and always rejoicing in his well-merited success, may appear as a close competitor for the blue ribbon.—D. T. Fish, *Hardwicke*.

CYCLAMEN PERSICUM CULTURE.

I enclose for your inspection leaves and blooms of Cyclamen persicum. The plants have been in flower from last Christmas, but are now just over. It ought to be a plant for the million, but strange to state, it seems to be one of the most neglected, yet one of the most easy to grow.

The treatment given here is to sow the seed in February. When the seedlings are large enough to handle they are pricked out in frames, then into small 60-pots, giving the last shift into large 60's, which are quite large enough for the first year.

From the time the seed is up, the plants should be kept in a moist, growing temperature, but by no means with a confined atmosphere, and at the end of ten or twelve months fine blooming plants can be had.

I kept a three-year-old corm from seed. It commenced blooming in the beginning of February, and continued producing flowers nearly to the present time, and not less than from seventy to ninety blooms expanded at one time. I merely state this to show its usefulness either for in-door decoration, bouquets, or cut flowers. The effect of forty or fifty good plants in a conservatory in the three worst months of the year can be easily imagined.

After the blooming period the plants are not allowed to become dry at any time of the year, or to be exposed to the mercy of the weather during the summer months. When they show signs of starting, they are repotted, but without destroying any of the roots, and as little as possible of the old soil is removed. They are kept in a cool house with a free circulation of air.—G. E., *Strawberry Hill*.

[The specimens enclosed were as fine as any we ever saw. The leaves measured nearly 4½ inches across; the petals were 1½ inch in length; and the whole were robust examples of perfect health and vigour.—Eds.]

EARLY TULIPS.

Although the Early Tulips are of great value for the spring decoration of conservatories, as well as for enlivening the flower garden before the summer occupants of the beds are planted out, and are indeed largely grown for both purposes, yet, considering their brilliant colours, their easy culture, and the cheap rate at which the bulbs can be purchased, it is surprising that they are not still more extensively cultivated. At present Hyde Park furnishes a magnificent example of the effect which they produce in large masses. There, extending for several hundred yards from Stanhope Gate, on the Park Lane side, towards the Marble Arch, is a series of beds which Mr. Mann, the Superintendent of the Park, has filled with these Tulips. Ten beds, all 25 feet long by 8½ wide, each containing one variety only, alone afford such a display of Tulips as it may safely be averred has never before been witnessed near London. All these beds have an edging of Arabis alpina, bearing a profusion of its white flowers, and within this a line of Crocuses, now over, surrounding a mass of Tulips, everywhere uniform in height, and without a blank. The varieties are Rex Rubrorum, double red; Tournesol, red and yellow; La Candeur, double white; Yellow Prince, single yellow, and White Pottebakker. Waterloo, single red, was also planted, but came into flower too soon. In the ten principal beds, and in others, altogether about 20,000 Tulips were planted, and although the arrangement of the colours is capable of some improvement, the very successful manner in which the bulbs have bloomed is most creditable both to Mr. Mann, and to Messrs. Gibbs & Co., of Down Street, Piccadilly, who supplied them. In the panels, besides Tulips and Hyacinths, the latter nearly over, there are Polyanthuses, the white-blossomed Iberis sempervirens, Alyssum saxatile compactum, Saponaria calabrica, and some autumn-sown annuals in bloom. It may also be here remarked that a number of Plane trees, some with trunks upwards of a yard in circumference, have been moved back from 15 to 20 feet, to make room for the much-needed widening of Park Lane, and, with a single exception, without injury to the trees.

Messrs. E. G. Henderson, of the Wellington Road Nurseries, have also a very fine collection in bloom, which is well worthy of inspection. It fills some forty beds, consists of several

thonsands of bulbs, and is more brilliant than even the Hyde Park display; but the general effect is not so good, owing to the vast number of varieties planted, and which do not correspond so exactly in height as is desirable. Of these the most noticeable are Sultana, crimson; Violacea purpurea, violet purple, pretty but small; Royal Queen, dwarf, deep crimson; Thomas Moore, orange buff; Silver Standard, crimson and white; Golden Prince, yellow; Bride of Haarlem, cherry-coloured feathers on a white ground; Cottage Maid, white, feathered with rose; Feu d'Anvers, scarlet, resembling Vermilion Brilliant in colour, but of dwarfer habit; Tournesol, double; Golden Prince, one of the best of yellows; Queen Victoria, white, fine cup; Couleur Cardinal, fiery scarlet; La Plaisante, purplish puce; Brutus, bright orange scarlet, with a narrow yellow border; Duc d'Autriche, scarlet, with a broad yellow belt; Wouverman, large, violet purple; La Majesteuse, deep crimson, with a narrow white edging; Duchesse de Parma, large and very fine, red and yellow; Proserpine, rather past its best, but still a fine rose; and Rosenkroon, crimson.

Independently of the Tulips, Messrs. Henderson's large houseful of Tricolor Pelargoniums is a sight of matchless beauty, and from the multitude of varieties which it contains in all stages of development, replete with interest.

In the Inner Temple Gardens Mr. Broome, less advantageously situated as regards London smoke, has also several beds of early Tulips in good bloom.

ROYAL HORTICULTURAL SOCIETY.

Weekly Show, *May 4th.*—The first of the Saturday shows to be held during this month and next took place to-day, and the collection brought together was a very good one. First, second, and third prizes were offered for collections of three Pelargoniums (Amateurs); of six plants, miscellaneous (Amateurs); of three Azaleas (Amateurs); of miscellaneous cut flowers, arranged in a basket (Open); and for the best exhibition of fruit (Open).

In the collection of three Pelargoniums the first prize was awarded to Mr. A. Wilkie, gardener, Oak Lodge, Addison Road, Kensington, and the second to Mr. W. Bartlett, Shaftesbury Road, Hammersmith. For six plants, miscellaneous, Mr. A. Wilkie was awarded the first prize for a fine plant of Dendrobium nobile, Azalea crispiflora, Erica candidissima, &c. Mr. W. Bartlett was awarded the second prize and also an extra prize for a collection of plants. There was only one exhibitor in the class for Azaleas—viz., Mr. A. Wilkie, who was awarded a first prize for Azalea variegata, Marie Vervaene, and Coronata. In the miscellaneous collection of cut flowers Mr. W. Earley, gardener to F. Pryor, Esq., Digswell, obtained the first prize, Mr. W. Bartlett the second, and the third was given to Mr. A. Wilkie. Mr. W. Lynn, gardener to Lord Boston, Hedsor Gardens, Maidenhead, gained the first prize for fruit. His collection consisted of a dish of Figs, a dish of fine Sir Charles Napier Strawberries, and a collection of Black Hamburgh Grapes, &c. Mr. W. Earley, Digswell, obtained the second prize, and was also awarded an extra prize for a collection of vegetables. An extra prize was also given to Mr. Morgan, Ball's Park, Hereford, for a dish of Keens' Seedling Strawberries and a box of cut Roses.

An interesting collection of plants from Chiswick, consisting of Roses, Lily of the Valley, Azaleas, Begonias, Pelargoniums, &c., made a very pretty exhibition.

Special Prize Show—*May 7th.*—Although nominally only one of the minor Shows of the Society, this was in reality an extensive and varied exhibition, filling the conservatory and the greater part of the two adjoining arcades, and from the large number of novelties produced it was possessed of more than usual interest; the day, too, was one of the finest we have had this season.

Class 1 was for a special prize offered by the Duke of Buccleuch, the President, for the nine best cultivated Azaleas, which was taken by Messrs. Veitch & Sons, notwithstanding their having so many of their finest specimens of these and other plants at the Paris Exhibition, where the firm has also taken the first prize for Azaleas. Those shown at South Kensington, which alone it is our province to notice here, were magnificent specimens, standing from 6 to 8 feet high, and the largest was 7 feet in diameter at the base, whilst the whole were in profuse bloom, with here and there a few fresh green leaves peeping forth and giving relief to the blaze of colour. The varieties were—Præstantissima, salmon rose; Extrani, rosy crimson; Criterion; Roi Leopold; Trotteriana, magenta crimson, splendid; Carnea superba, salmon rose; Magnifica, white; Dilecta, rose; and Chelsoni, orange scarlet.

In Class 2, for the best nine Roses in pots, the prize was also offered by the Duke of Buccleuch, and was taken by Messrs. Lane & Son, with beautiful examples of Souvenir d'un Ami, Vicomtesse de Cazes, yellow, Chénédolé, Anna Alexieff, Charles Lawson, Paul Perras, Gloire de Dijon, Victor Verdier, and Coupe d'Hébé. Mr. William Paul received an extra prize for another beautiful collection, of which the star was a most graceful plant of Souvenir d'un Ami in splendid bloom, with remarkably fine examples of Anna Alexieff, Paul Perras, Paul Delameilleray, Victor Verdier, Madame C. Wood, Comtesse de Chabrillant, Madame de St. Joseph, and President. Messrs. Lane and Son also contributed several young plants of Maréchal Niel.

Prizes were also offered by Mr. G. F. Wilson, F.R.S., and the Duke of Buccleuch, respectively for the best twenty new Roses, and the best six Zonal Pelargoniums, but no competitors came forward to claim either.

Mr. W. Wilson Saunders offered prizes for the best ten Orchids and the best six Show Pelargoniums. The former was taken by Mr. Penny, gardener to H. H. Gibbs, Esq., St. Dunstan's, Regent's Park, with Phalænopsis grandiflora with three fine spikes of large flowers, Cypripedium villosam in fine bloom, Saccolabium curvifolium, and Lælia cinnabarina, each with four spikes; Dendrobium primulinum, with seven spikes; Vanda suavis, V. tricolor superba, the yellow and brown Oncidium sarcodes, and the Fox-brush Aërides.

Mr. Saunders's prize for Pelargoniums was taken by Mr. Turner, of Slough, with finely-bloomed plants of Patroness, Beacon, Desdemona, Mdlle. Patti, Empress Eugénie, and Rose Celestial; and Mr. Wiggins received an extra prize for half a dozen plants which have been noticed in a previous report; Roseum was very showy.

Major R. Trevor Clarke offered a prize for the best collection of fragrant-blossomed plants, but only one exhibitor came forward—Mr. J. Reeves, jun., Campden Grove Nursery, Kensington, and his plants were small, though numerous enough. They consisted of Mignonette, Stocks, Gardenia florida, Ixora acuminata, Stephanotis floribunda, Daphnes, Boronia serrulata, Nerium splendens, Orange tree, Acacia armata, Jasminum ligustrifolium, Heliotrope, Petunia, Rose, Lily of the Valley, and three or four other plants.

New plants, as already remarked, constituted a leading feature, being shown in great numbers and beauty. In Class 8, for the best six sent out in 1865 and 1866, Messrs. Veitch were first with Primula cortusoides amœna, with rich rosy purple flowers as large as a two-shilling piece; the beautiful Maranta roseo-picta, with deep green foliage, crimson midribs, and a zone of the same colour, the under side of the leaf being reddish purple; handsome specimens of Maranta Veitchii, Verschaffeltia splendida, Dieffenbachia Weirii, and Begonia Pearcei with rich velvety dark green leaves veined with pale green. Mr. Bull was second with Maranta roseo-picta, Verschaffeltia splendida, the silvery-veined Fittonia argyroneura, the rose-spotted Bertolonia guttata, Zamia villosa, a handsome graceful species, and Anthurium regale, with large Caladium-like leaves of a bronzy green colour prominently veined with pale green, a very effective species. Mr. Williams, of Holloway, sent the Variegated New Zealand Flax, Dieffenbachia Weirii, Dracæna sanguinea, Maranta Lindeni, a pretty Gleichenia with the under side of the fronds silvery, and a panful of Chrysanthemum Sensation, which, in general appearance, would form a good substitute for Lady Plymouth Pelargonium.

In Class 9, for the best six plants sent out in the present year, Messrs. Veitch were again first with Sanchezia nobilis variegata, with large obovate leaves with yellow bands radiating from a yellow midrib, a very handsome ornamental-foliaged plant; Coleus Veitchii, from New Caledonia, with dark chocolate leaves edged with bright green; Panicum variegatum (also from New Caledonia), with rose, white, and green foliage, and which will probably make a fine basket plant; Dieffenbachia Pearcei, with large leaves having pale green and silvery markings; Hypocyrta brevicalyx, from Ecuador, with nearly orbicular silvery-veined leaves; and Lomaria ciliata, from New Caledonia. Mr. Bull was second with two Peruvian Dichorisandras, named D. mosaica, with dark green leaves, lined transversely with pale green, and brownish purple on the under side; and D. undata, with undulated dark green leaves, longitudinally banded with pale green; Agave macrocantha, with glaucous pale green leaves edged with bold brown spines; the handsome and robust-looking Adiantum Lindeni; Maranta illustris; and Bignonia ornata, from Rio Negro, with broad-lanceolate leaves, which when young are of a bronzy hue with a rosy band along the midrib, but which becomes silvery in the older foliage, which is elsewhere of a deep green colour.

In Class 10, for the best new plant shown for the first time in flower, the prize was taken by Mr. Bull, with Dalechampia Roezliana rosea, with bright rose-coloured bracts. In the same class a scarlet-flowered Begonia, from Bolivia, shown by Messrs. Veitch, and which promises to be a great acquisition, received a first-class certificate; a similar award was made to Mr. Bull, for Ptychosperma regalis, a handsome East Indian Palm.

Class 11, was for the best new plant with ornamental foliage, and in this the prize was taken by Messrs. Veitch, with a species of Alocasia, from the East Indies, having nearly heart-shaped bright green leaves, with dark chocolate blotches in compartments divided by the veins.

In Class 12, for the best new garden seedling, the prize was also taken by Messrs. Veitch with a pretty hybrid Cattleya.

Messrs. Veitch, in addition to their exhibitions in the above classes, contributed an extensive collection of recently introduced and rare plants, among which were Anthurium Scherzerianum with three splendid spathes, Hippeastrum equestre, the beautiful Bertolonias margaritacea and guttata, the red-veined Gymnostachys Pearcei, a panful of Davallia alpina, the handsome Retinospora plumosa, Miconia peruviana, with large and beautiful Sphærogyne-like foliage, Palicourea discolor, Maranta Veitchii, and Acalypha tricolor with coppery

foliage. From Mr. Bull came a similar collection, including Terminalia elegans, Dieffenbachia Weirii, the silvery-mottled Habenaria margaritacea, Eranthemum igneum, with deep green leaves and bold orange veins, Rhopala aureum, having the stem and leafstalks covered with orange down, Bertolonias, Anæctochilus petola marmorea, Dæmonorops elegans, a handsome-looking plant for table decoration; several new Ferns, &c.

Of fine-foliaged and flowering plants several remarkably fine mixed groups were exhibited. That from Messrs. Lee, to which the first prize was awarded in Class 13, consisted of a large and very handsome specimen of Alocasia metallica, Rhopala corcovadense, Croton variegatum, Theophrasta imperialis, Dicksonia antarctica, with a thick trunk and very graceful head, Pandanus elegantissimus, very large and fine, one of the finest specimens of Genetyllis tulipiferum which we have ever seen; Medinilla magnifica, with about sixteen splendid panicles of bloom; white Azalea Lecana, Erica Cavendishii, Polygala cordifolia, and the white-flowered Pimelea spectabilis. Mr. Williams, who was second, had remarkably fine specimens of Latania borbonica, Variegated Aloe-leaved Yucca, Pandanus elegantissimus, and Alocasia metallica; also Azaleas, Eriostemon pulchellum, Erica Cavendishii, and other flowering plants. An extra prize was awarded to Mr. Fairbairn, gardener to the Duke of Northumberland, Sion who had a noble plant of Seaforthia robusta, large specimens of Alocasia zebrina, and macrorhiza variegata, Phalænopsis grandiflora, Vandas, &c. Similar awards were made to Mr. Wilkie and Mr. Gell.

Messrs. Lee had also a first prize for the best twelve stove and greenhouse plants in flower. These comprised Azaleas, an Eriostemon, Ixora coccinea, Acrophyllum venosum, very pretty; Boronia pinnata, the lilac-flowered Tetratheca ericæfolia, Genetyllis fuchsioides, Heaths, and Aphelexis.

Of Cape Heaths, shown in Class 15, rather small specimens came from Mr. Wilkie, who was the only exhibitor; and in Class 16, for exotic Ferns in 12-inch pots, Mr. Williams was first with good examples of Dicksonia antarctica, Alsophilas, Gleichenias, a fine Platycerium grande, Adiantum Feei, Todea superba, and others.

Of miscellaneous subjects Messrs. Veitch contributed a charming group, consisting of Azaleas Stella, Marie Vervaene, and Holfordii in splendid bloom; the white-flowered Rhododendron Sesterianum, Hoteia japonica, Clianthus Dampieri, Coleus Veitchii, and the variegated-leaved variety of Hemerocallis fulva. Messrs. Lane had a pretty group of Azaleas; Mr. Burley, of Bayswater, a group of Palms and Dracænas, for which he received an extra prize; Mr. William Paul, a box of cut-blooms of spring and early summer flowering shrubs; and Mr. Dean, Ealing, cut blooms of double Tulips. Mr. Anderson, Meadow Bank, and Mr. Sherratt, gardener to J. Bateman, Esq., Knypersley, also sent cut Orchids.

Floral Committee.—The Special Exhibition for prizes offered by members of the Council, and supported by prizes from the Society, must be considered a great success. The duties of the Floral Committee were, as we always wish them to be, somewhat heavy, and the awards were numerous. Mr. Muir, gardener to Sir P. M. de Grey Egerton, Bart., M.P., received a first-class certificate for Epidendrum spathicum cnemidophorum, with three splendid spikes of flowers. Messrs. Low, Clapton, exhibited eighty specimens of a beautiful old Orchid with many varieties, Cattleya citrina, much admired, and for which a special certificate was awarded; Odontoglossum citrosmum album, which received a first-class certificate, and a collection of beautiful Orchids, for which also a special certificate was awarded. Mr. Dean, Ealing, sent a variety of Cabbage, Brassica oleracea, with variegated leaves. Mr. Turner exhibited several seedling Alpine Auriculas of first-rate quality, many of them rather past their prime: Bertha, a dark shaded purple, had a first-class certificate; Novelty, a paler shade, a second class one. Mr. Turner also exhibited several seedling Fancy Pelargoniums. Maid Marian, a pleasing variety, not quite perfect in form, had a second-class certificate; Belle of the Season, a perfect flower, one of the first class; Pink of Perfection, a splendid rosy carmine, a first-class certificate; Marmion, deep violet rose, one of the second class; Perfection, a first-class, and Brightness, a charming variety, a like award. Messrs. Rollisson, Tooting, had for Erica Turbullii, a first-class certificate, and one of the second class for Erica tubiformis. Mr. Turner, with his usual liberality, decapitated a large collection of his first-rate Tulips, which were awarded a special certificate.

From Messrs. Downie & Co. came Nosegay Pelargonium Rose Stella, a plant of great merit, dwarf in habit, colour distinct, a very useful bedding plant, quite worthy of the type Stella, and which was awarded a first-class certificate. Mr. William Paul sent a large collection of seedling Zonal Nosegay Pelargoniums, many of them of great merit, but the specimens were too small for any decision as to merits. Waltham Nosegay, in every point to be commended, was awarded a first-class certificate; Dr. Hogg, a darker shade than Amy Hogg, an excellent variety, was awarded a first-class certificate. He also sent Silver Wing, Ossian; of the Tricolor section, Red Admiral, Rouge et Noir, California, Variegated Cybister, and many others. An Ulmus from Japan, also shown by Mr. W. Paul, and very distinct, was awarded a first-class certificate. Iberis carnosa, a very useful dwarf plant for rockwork, which came from Messrs. Backhouse, of York, also had a first-class certificate. Mr. Williams, Paradise Nursery, Holloway, sent Azalea Reine des Roses, splendid in colour, but without outline and form; also Amaryllis aurantiacum. From Mr. Barnes, Camberwell, came Azalea Her Majesty, a fine flower, which had received a first-class certificate on a former occasion. Mr. Watson, St. Alban's, exhibited several seedling Zonal Pelargoniums; among the Tricolors, Mrs. Dix and Miss Watson both retained their good character. Excelsior, Annie Merry, and Enchantress must be seen again. Mr. Richards, gardener to Lord Londesborough sent a Saccolabium curvifolium of a good variety, which was awarded a special certificate. The new plants exhibited in classes 10, 11, and 12 were awarded the following certificates:—Messrs. Veitch, Cattleya, hybrid variety, first-class; Alocasia species, very beautiful, dark-spotted leaf, first-class; Begonia species, with very singular scarlet flowers of a new form, first-class. Mr. Bull, Ptychosperma regalis, first-class certificate. Mr. Bull also exhibited a bright rose seedling Azalea Charmer, beautiful in colour but deficient in quality. Many other specimens were exhibited which have been previously noticed, and maintain the good characters assigned them.

Fruit Committee.—Mr. Turner, of Slough, received a special certificate for three very well ripened bunches of Muscat Grapes; also for three bunches of Black Hamburgh, as black as Sloes, and covered with a fine bloom. Mr. Merrett, Battersea, sent a box of Sir Charles Napier Strawberry, very fine in flavour, and had a special certificate for six plants of the same in pots, loaded with fine fruit. A similar award was made to Mr. Fairbairn, Sion, for seven pots of Keens' Seedling, likewise bearing an abundance of finely-ripened fruit. Mr. Gardiner, Weston House, sent a dish of Peaches, and Mr. Earley, Digswell, Sturmer Pippin, Sam Young, and Cockle Pippin Apples in good preservation. From the same exhibitor came fine heads of Williams' Alexandra Broccoli, which received a special certificate, and from Mr. R. Dean, Ealing, selected Stanstead Park Lettuce, a most excellent Cabbage variety.

General Meeting.—J. Bateman, Esq., F.R.S., in the chair. The business was confined to the election of sixteen new Fellows and the admission into union with the Society of the Stour Valley Horticultural Society, Ludlow Horticultural Society, Bodmin Cottage Gardening Society, and Basingstoke Horticultural Society.

ENTOMOLOGICAL SOCIETY'S MEETING.

The April meeting of this Society was presided over by Sir John Lubbock, F.R.S., the President.

Mr. S. Stevens exhibited several specimens of the rare and very remarkable Beetle Dumaster Blaptoides (belonging to the family Carabidæ), from Japan. Mr. Pascoe exhibited and described a new Longicorn Beetle from Greece, under the name of Toxotus Lacordairei.

Mr. F. Smith exhibited a fine British species of Ichneumonidæ (Rhyssa persuasoria), which appeared to have worked its long ovipositor (bradawl fashion), through a piece of Fir wood in quest of the larva of Sirex juvencus, on which it is parasitic, part of the ovipositor being left in the wood. He had always supposed that the Ichneumon inserted its ovipositor down the hollow made by the Sirex larva instead of making a hole for itself. The late Mr. Edward Doubleday had, however, told him that he had seen in North America many female specimens of Pelecinus, an allied genus, with their long abdomens inserted into the stem of a tree, apparently for the purpose of egg-laying; unable to extract the abdomen again, they had perished *in situ*. Mr. Bates inquired whether an ovipositor was not a modification of an abdominal segment. Mr. Smith, on the contrary, considered it to represent the aculeus; and Mr. Wallace suggested that the sting was a modification of the ovipositor, egg-laying being the primary use, defence the secondary and acquired use.

Mr. G. Saunders exhibited a number of Podurida, minute spring-tailed insects, found on the surface of pools left on the melting of the snow in the north of Yorkshire.

Professor Westwood communicated a paper entitled "A Decade of new Mantispedæ in the Oxford Museum."

MR. DIXON'S TREATISE ON TRICOLOR ZONAL PELARGONIUMS.

Mr. Dixon's small pamphlet, of which you in your last number have given so able and just a review, is one which at the present moment, when the Tricolor Zonals are receiving so much attention from both practical horticulturists and amateurs, will be found extremely useful. The simplicity and conciseness of the several hints suggested are a great recommendation to this treatise; and I am certain that lady amateurs especially will find it not only of great assistance to themselves in their interesting experiments, but that it will enable every admirer of these splendid garden ornaments who had practically little knowledge on the subject, to give ample and safe directions to the gardener who may be required to carry out his or her desires. There are suggestions in this little book worthy of some consideration; and although to the practised skill of the horticulturist no very new idea may be suggested, it is a book well worthy of a shilling being spent for its perusal.—J. D., A Constant Reader.

VINE BORDERS.

There has been so much discussion lately in your pages, respecting the making and management of Vine borders, that it may be thought presumption in an amateur of only a few years' experience to put in a word among such skilful growers.

I cannot help thinking that Vine borders, as a rule, are too much enriched, which is, I think, not only wasteful but positively deleterious, as productive of coarse long-jointed shoots. My present Vines were planted in March, 1865, inside a house 30 feet by 16, the front built on arches, and with an outside border of lime-rubbish and common garden soil, about 15 feet wide. The inside border was made with rotten horse-manure, bones, and lime-rubbish, and a small quantity of charcoal added to about four times the quantity of common soil, and I have occasionally given waterings of weak liquid manure, such as guano water and diluted chamber lye. The outside border was cropped the first year with early Potatoes, and last autumn it was dug up and a small quantity of horse-manure pointed in. The roots were found to have gone through, but were cut back.

The house is in two divisions. In one I have a Muscat of Alexandria, a Bowood Muscat, a Muscat Hamburgh, and a Lady Downe's. In the other, or cooler compartment, are a Lady Downe's, a Purple Constantia, two Black Hamburghs, and one Royal Muscadine. I have been firing a little since the end of February, but ceased doing so in the cooler compartment at the end of March. In the warmer division the Muscat Hamburgh bunches are 10 inches long and largely shouldered. the berries the size of large peas; the others are rather smaller. In the cooler division the Grapes are just beginning to set. I pinch very severely at the first joint beyond the fruit, and afterwards at the second leaf, and the shoots are sturdy and short-jointed, and the leaves large, often 10 inches across each way, every eye showing fruit, though I only allow about seven or eight bunches this year on a Vine. I give more air than many, as I think it conduces much to flavour, which I prefer to size, and next month (May), I intend to have the back shutters partly open all night to prevent early scorching, my aspect being south-east.

Some of my neighbours have covered their borders with a thick coating of long dung, and their shoots are gross and long-jointed, with puny flower-stalks six or seven joints from the stem; but mine have only four or five joints, and when in full flower are only 5 or 6 inches from the stem. I do not believe that Vines require such constant dressings of rich manure as many apply to them. They do not get them in the foreign vineyards to anything like the extent; and other fruit trees, when established, are left to themselves, and bear large crops of fruit, as do Vines on walls in good aspects and climates, their roots running under gravel walks and in all kinds of rough soil, and only wanting good drainage and plenty of sun heat.—J. C. Barnham.

SORGHUM TARTARICUM.

We have read the very disparaging notice of the above novelty in a late number of the Journal with much surprise, and hasten most willingly to satisfy your correspondent, "W. P.," in last week's issue, as to our position respecting it, although our advertisement, if correctly read, contains abundant explanation.

Our house has long been celebrated for introducing novelties of the vegetable world, and we are compelled in most instances (excepting when of our own raising), to rely upon the description given us by the raiser or introducer, as the case may be; but at the same time we specially avoid personally guaranteeing the excellence of any novelty until we have proved it at our trial grounds. In this case we intimated most distinctly that the description is "as given us;" and in the advertisement of S. tartaricum we say, "that we have not yet proved its qualities," followed by a verbatim description from our correspondent, whose testimony we are by no means disposed to question.

A doubt has been expressed as to S. tartaricum possessing sufficient hardiness of constitution to thoroughly ripen its seed in this variable climate; but as our correspondent assures us it is "quite hardy," we have every reason to believe the variety as offered by us has not been sufficiently tried in this country to warrant its condemnation, and we suspect the reports to which we allude emanate entirely from hearsay evidence, or from a trial of an inferior kind of Sorghum incorrectly supposed to be synonymous with the sort in question.

We cannot, therefore, allow our correspondent's description to be disputed upon such unsatisfactory evidence; and as we have made a considerable sowing at our seed farms in Essex, besides distributing large quantities to our customers, we have no doubt the question of its adoption as an English cereal, or a valuable forage plant, will be effectually determined by this season's trial. We may add, that should it fail as a corn crop, it is reported to possess remarkable qualities as a forage plant, for which purpose the Sorghums generally have proved more or less adapted.—James Carter & Co.

PARIS UNIVERSAL EXHIBITION.

To those who have been accustomed to visit or to report on the flower shows in England, a visit to the horticultural portion of the Great French Industrial Exhibition will be attended with a singular mixture of perplexity and disappointment. Unlike the exhibitions we are accustomed to see in our own country, where all the subjects are gathered together in one, or, at least, in contiguous places, and the various collections in the same class are so placed that they can easily be compared, or serve to form groups that contribute pleasing effects in form and in colour, the French Exhibition is distributed over a large surface in detached glass houses and sheds without any apparent system, or without any attempt either to produce effect or to afford pleasure.

The horticultural part of the Exhibition occupies one of the four equal compartments of the park which surrounds the great building, and it is most skilfully and tastefully laid out, producing the finest landscape effects which undulating grounds, water, rockwork, grottoes, trees, and shrubs are capable of, and this upon a scale which affords ample scope to do justice to every feature that is represented. An idea of the manner in which this has been carried out will be obtained from the accompanying figure, which, while it represents the disposition of the ground, fails to convey any conception of the artistic beauty of the place. It will be seen from the figure that glass houses are distributed throughout the whole of this space, and it is in these houses that the various horticultural exhibitions take place, with the exception of the hardy ornamental trees and shrubs, which are arranged in groups, and contribute to the planted effects of the ground. Round the large conservatory, or Serre monumentale (1), the Conifers are arranged, in which class our enterprising countryman, Mr. Veitch, plays a prominent part, contending for and maintaining the honour and reputation of his country. Notwithstanding the great disadvantages of the long voyage by sea and land over which his collection of Conifers had to be transported, he nevertheless carried off at the second series the first prize. They are a beautiful lot, and whether the great beauty of the specimens or their commercial value is considered they are a valuable collection.

To enable us to deal with this subject systematically, we shall begin at that corner of the enclosure which is indicated by the "Galerie des Fruits et Legumes" (16). This "Galerie" is a long covered shed, about 50 feet long and 8 feet wide, a lean-to against a wall, and a long table running the whole length. The "Legumes et Fruits," the vegetables and fruits, that have hitherto been exhibited here, are not such as to attract any one from a great distance to see them. The season is yet too early for any such exhibitions to be attractive, and therefore our readers will not be astonished when we say that with the exception of a few withered Apples, some very unhappy-looking Oranges and Lemons, and some of those large specimens of Uvedale's St. Germain one sees in Covent Garden Market, and which appeared to be the worse for the repeated services they had already performed, there is really nothing to look at in the fruit way. Within these last few days a dozen or two pots of forced Strawberries have made their appearance, and do ample credit to the good cultivation of Mr. Charles Henry, of Bagneux. It appears, however, that this gallery is put to other uses than the exhibition of vegetables and fruits, the vacant space being filled during the last fortnight of April with cut blooms of Hyacinths and Tulips from Mr. Krelage, of Haarlem, and which, if he had seen them, were not likely to have excited great alarm in the mind of Mr. William Paul, who apparently will be permitted to retain the laurels he has already won for some time to come, against both Dutch and French growers at all events.

The third series of exhibitions commenced on the 1st inst.,

and will continue till the 14th, when the fourth series will commence. The first class consisted of Indian Azaleas and Rhododendrons. The former formed a very creditable exhibition, but the plants were not so large as we are accustomed to see at our London exhibitions, being rather of the kinds that may be grown in eight and nine-inch pots. Messrs. Veitch and

Sons were there with some of their large specimens, which, in the classes in which they were exhibited, surpassed, as might have been expected, all others. In the class for the best collection there were three exhibitors—M. Grangé, of Orleans, who had ninety-five plants; M. Van Acher, of Res, near Corbeil, who had 240; and Messrs. Thibaut & Keteleer, of Paris, who had 185. Although M. Van Acher's collection was the most numerous, that of Thibaut & Keteleer was so much superior to it, and the plants so much better bloomed, they received the first prize, M. Van Acher second, and M. Grangé third. In the class for fifty varieties, MM. Ambroise Verschaffelt, and Dominique Vervaene, of Ghent, were the only exhibitors, and both collections were highly meritorious; but M. Vervaene carried off the first prize, the plants being decidedly better bloomed.

In the class for six specimens remarkable for their size there were three exhibitors, M. Joseph Vervaene and M. Graet-Brac, of Ghent; and Messrs. Veitch & Sons, of London. The plants of the last were far beyond those of either of the other exhibitors, and, consequently, received the first prize. The admiration which these plants excited to the wondering eyes of the Parisians, was expressed in the most enthusiastic terms. In the class for twelve varieties sent into commerce since 1865, M. Vandergruyssen, of Ghent, was first; M. Dominique Vervaene second; and Madame Léon Maenhaut, all of Ghent, third. For seedlings there were five exhibitors, the successful ones being Dominique Vervaene, of Ghent, who had a first prize for Comtesse de Flandres, and a second for M. Barillet; and M. Beukelaer had a third prize for a double rose and a double white variety. For the best flowered specimen combined with good culture there were six exhibitors, but the competition was confined to M. Dominique Vervaene and Messrs. Veitch and Sons. The former was the successful exhibitor, and Messrs. Veitch came second, but the difference between them was only one point; both specimens were very handsome.

The exhibition of Rhododendrons was of a very poor description, both as regards the plants and the flowers. There was not in all the collections a single flower that would have passed muster at any meeting of the Floral Committee, and

one need not, therefore, occupy space in describing that which has no object of interest attaching to it.

The great stake of the day was in the New Plants, and the rivals were Messrs. Veitch, of Chelsea, and M. Linden, of Brussels, both the victors in many a hard-won fight. The first class was for collections of Stove Plants of recent introduction. In this Messrs. Veitch were the only exhibitors, and a finer or more interesting lot we never saw exhibited when the number is taken into consideration, there being no less than thirty plants in all. Among them were to be seen several of great novelty and interest, such as a Cinchonaceous plant with long broadly-lanceolate leaves, and with bright red midrib and veins, from Bolivia; a singular species of Begonia from Peru; a Bertolonia from Madagascar; a Drosera from the Cape of Good Hope; several species of Dracænas from the South Sea Islands; Crotons, and a new species of Dicksonia. There were also a fine specimen of Anthurium regale, Maranta roseo-picta, and Dieffenbachia gigantea. It was in Class 2 that the great rivalry took place. It was for six plants newly introduced, distinct. Messrs. Veitch and Mr. Linden each showed two collections. That on which the first prize was decided, Messrs. Veitch's, consisted of a new species of Philodendron; two new Dracænas, one beautifully variegated green and white, and named Dracæna regalis; the other the same colour as D. ferrea variegata, but with much larger and broader leaves, and named magnifica; a Croton, from New Hebrides, named C. Veitchii; Sanchezia nobilis variegata; and Aralia Veitchii, from New Caledonia. Mr. Linden had a new Commelinaceous plant which has leaves a yard long, and is said to produce flowers of azure blue; Bignonia ornata, from Rio Negro; the Dichorizandra mosaica which he exhibited at the International Exhibition of London in 1866; Maranta virginalis, Ficus dealbata, and Maranta princeps. The first prize was awarded to Mr. Linden, with 20 points; and the second to Mr. Veitch, with 19¾. The difference being so slight it may be thought, and was thought by many, that they should have been equal; but we believe it is a Perso-Median principle of the Imperial Commissioner, that no two things can be of equal value, not even a florin and a two-shilling piece, and, therefore, the Juries are not permitted to make equal awards. The second collection of Mr. Linden consisted of Hemerocallis nova, a green and white variegated variety, from Japau; Cyanophyllum spectandum; Dieffenbachia nobilis, a new species of Iresine, a new species of Spathiphyllum, and Echites rubrovenosa. Messrs. Veitch's second collection contained a species of Aralia, from New Caledonia; Dieffenbachia Pearcei, Coleus Veitchii, a beautiful striped new species of Pandanus, from New Hebrides, Retinospora filicoides, and a beautiful new double Clematis, in the way of C. Fortuni, but light purple in colour, called John Gould Veitch. For this collection Messrs. Veitch received a third prize, and Mr. Linden received a fourth for his.

For a collection of choice plants of recent introduction, and which formed the third class, Mr. Linden and Mr. Ambroise Verschaffelt were the only exhibitors. Mr. Linden's consisted of Gunnera manicata, Anthurium crinitum, Anthurium trilobum, Adelaster sp. nov., Maranta Legrelleana, Maranta setosa, Maranta chimboracensis, Caladium sp. nov. In the fourth class also there was but one exhibitor, M. Ambroise Verschaffelt. It was a much larger collection, and contained Cibotium regale, Acer formosum, Acer sanguineum, Acer ornatum, Acer jucundum, A. amœnum, A. Frederici-Gulielmi, Ficus Ghiesbreghti, Maranta illustris, pulchra, and Verschaffelti, Agave mirabilis, compacta, grandis, and spectabilis, Aralia Sieboldi foliis reticulatis, Dracæna lentiginosa and Verschaffelti, Aristolochia insignis, Daphne speciosa, Echites rubrovenia, Cordyline Guilforglei, and Tillaudsia grandis. For this collection Mr. Verschaffelt received a first prize, and Mr. Linden a third. The last of the classes in this group was for a single specimen of a new plant remarkable for its culture. Here Messrs. Veitch were first with a splendid specimen of their Maranta Veitchii, and Mr. Linden second with a fine plant of Anthurium regale.

In Orchids there were only two exhibitors, Mr. Lüddemann and Messrs. Thibaut & Keteleer, of whom the former took the first prize and the latter the second, and their specimens were not such as to require any special notice. There was, however, a specimen of Vanda suavis, with several large masses of Cattleya Skinneri, from the Duc d'Agen, which not even equalled anything of the kind ever seen in England.

The only other objects worth noticing were some extraordinary bundles of Asparagus, exhibited by Messrs. L'Hérault-Salbœuf et fils, Rue de Sannois, Argenteuil, which for size have perhaps never been surpassed and rarely equalled. M. Lonis L'Hérault also exhibited some of extraordinary size, though not equal to the former.

VINES AND VINE BORDERS.

Mr. Wills has carried the discussion of this subject from the garden under his own charge to that of Mr. Meredith, and if any inconvenience arises from this change, I shall not consider it is my affair. I can only conclude he thought this would give him an advantage; be it so. I shall try and show him it is a mistake for him to treat a matter involving such large sums in such a light way, and also that he has not given us information enough fairly to support his deductions.

The first time Mr. Wills makes reference to my letter is in that very involved sentence or question, beginning with the words "supposing it to cost £60 or £100, according to size, and with a view to its lasting in good condition sixty or a hundred years." I never hear of any one finding in the dictionary of facts either the word "if" or "suppose;" but let me ask, If a border which costs £60 will last sixty years, and one that costs £100 one hundred years, as he "supposes," why one which costs £15 should not last fifteen years, and one that costs £20 twenty years? and are there in the higher-priced borders some more expensive materials used which cannot be afforded in the cheaper ones? and is this some patent manure "that will last in good condition sixty or a hundred years?"

In his description of the early vinery, 65 feet long and 23 feet wide, Mr. Wills tells us the depth and width of the inside borders; but in speaking of those on the outside I see only the depth and not the width; nor do I in any single instance see the size of any outside border given! When I was at Garston Mr. Meredith told me that the use of these small borders was to save watering, and not to support the Vines, and I wish to know if he has changed his mind. Mr. Wills tells me "he did not make an examination of the Vine borders," "but that any Grape-grower can tell from the Vines that the borders were well filled with fine healthy roots," "and that I may take his word for it that the roots are to be found in quantity both outside and in," adding, "if there is any difference in their healthiness, those in the outside border perhaps will be the best." I am a Grape-grower, and I can tell by looking at a Vine if it has plenty of roots to support the crop it is carrying; but, I confess, I cannot tell by looking at a Vine in which border the greater part of its healthy roots are. I do not say that this cannot be done; but will Mr. Wills tell me how, and excuse the doubt implied in the question?

After giving us a description of the semi-lean-to, 128 feet long by 17 wide, and its wonderful crop last year, Mr. Wills asks me "what I think of the show system of Vine-border-making after that;" a very plain question, and I will try as frankly to answer it. The examples given are a Lady Downe's bearing twenty-two bunches, averaging 1½ lb., or 33 lbs. in all; a Barbarossa with 30 lbs. contained in three bunches, a second Lady Downe's with sixteen fine bushes, a second Barbarossa with three bunches weighing about 20 lbs., and Child of Hale with four bunches, the united weight of which would be about 36 lbs., the largest counting for 12 lbs. I do not think I can judge of the powers of a border by any one year's result. Mr. Wills says this house has been planted about six years; surely Mr. Meredith would not grow these Vines so many years without cropping them, that he might astonish the world in the end by crowding six years' crop into one. I also want to know how many canes each Vine had, the distance they are planted apart, and how much the cane or canes had been shortened the previous year; which means, Were these bunches produced from spurs or new canes? Till I know all this I must conclude that each Vine had only one cane 17 feet long, and which cane was pruned on the close system. May I calculate the previous year's crops at this rate progressively?—I will take the medium 33 lbs.; this is at the rate of 5½ lbs. per year's growth, the year of planting not being counted:—Sixth, 33 lbs.; fifth, 27½ lbs.; fourth, 22½ lbs.; third, 17½ lbs.; second, 12½ lbs.; first, 7½ lbs.; total, 120½ lbs. Say if a Vine so treated can produce half of this 120½ lbs. in the first seven years of its growth, or 60 lbs., it has done well; and if the house would average it, then it is my opinion that I should differ from Mr. Wills in his conclusion that there is an outside border needed, and should be quite willing to point to these facts as being a proof that my opinion was correct.

I am surprised that after such facts as are here described

Mr. Wills should have presumed to tell Mr. Meredith that if he did not add an outside border, "and that soon," he would "spoil his magnificent Vines;" but let us examine what this advice amounts to. He tells us the inside border is 12 feet wide and 5 feet 6 inches deep, and gives it as his opinion that Mr. Meredith should expend £130 to add an additional 12-feet-wide border outside; if this is also 5 feet 6 inches deep, which is surely deep enough, it will be in all respects the same size as the one inside, and if it cost £130, which he says it will, I think we may fairly presume the inside border will cost the same sum, or £260 for the pair. Again, if the second is so imperatively needed, as I gather his language means, for he says, "but he will be obliged to make it, and that soon," though this border has only been made six years, I conclude the second will be as quickly exhausted. Here, then, is an expense of £260 for borders each twelve years. Let me, then, ask him the question he asks me:—"Which is the less expensive mode of making a Vine border, to make it thoroughly in the first instance, supposing it to cost £60 or £100, according to size, and with a view to its lasting in good condition sixty or a hundred years," or to make one costing £130 every six years? Mr. Wills mixes up his argument on Vine borders with his praise of Mr. Meredith's vineries; either subject is worthy of more consideration than he gives it. Of the first—the border-making, I still think the proper way of treating it is as a commercial speculation, where results in value in the shape of a crop of Grapes, or the crops of a series of years, are set against the cost incurred; and if in this matter I have wrongly judged Mr. Wills, and he really does desire to prove that he wishes to place before us a plan of growing Grapes economically, he has only to do so in the practical way I have indicated, and I will retract anything I have said that will carry an imputation that he is wanting in regard for the strictest economy in such outlay.—G. H.

NOTES AND GLEANINGS.

We noticed approvingly lately the approaching exhibition of Tricolored Pelargoniums at the Royal Horticultural Society, and we have since been requested by the Rev. Mr. Dix, Chairman of the Floral Committee, to publish the following:—"In common with many amateurs and others much interested in the variegated form of the Zonal Pelargonium, I am looking forward to a grand treat on Tuesday, May 21st, when I trust the invitation put forth by the Council of the Royal Horticultural Society will be cheerfully responded to. I believe that the idea of an exhibition of these plants has been most favourably entertained by all the raisers of this class of Pelargoniums, and that a desire prevails that a magnificent display should be made on the 21st. It may be well, perhaps, for the benefit both of amateurs and others, briefly to sketch out what is expected from exhibitors on this occasion. It is desirable that groups or collections should be shown, including the earliest form of variegation, showing its progress to that of the present year, that a paper be sent with each collection, stating the advance or improvement gained from an original point—for instance, from Mrs. Pollock to the seedlings of the present year. It would be well if each exhibitor would state whether accurate entries and notes have been made and kept of the parentage of seedlings, giving the names of the male and female parents. One great object in view is to prove, if possible, whether the skill of the gardener (a point at present doubted by some) has any certain control over Nature in producing these variegations. It will not be necessary that a tedious and lengthy paper should be written; a simple proof stating that definite results have been achieved by certain proceedings in hybridising is all that is required or expected. The names of the parent plants written on the label bearing the name of the seedling plant, would be most interesting. I cannot but think that much valuable information would be thus afforded to the horticultural world; also that subject matter for a conversation at the meeting to be held afterwards, would be given, which, doubtless, some of our botanical and horticultural friends would avail themselves of. New and distinct varieties separately entered for the decision of the Floral Committee, will receive certificates according to merit, and medals will be given to such groups or collections accompanied with the written information required, as shall be considered most worthy. Let not the amateur be afraid of exhibiting on this occasion. The raiser of three or four seedlings of merit, after careful and thoughtful selection of parents for hybridising, may have something of greater interest to exhibit, than seedlings collected from all parts of the kingdom, of the origin of which no trace can be shown. It would be well for those who intend to exhibit on the 21st, to give due and early notice of the same to Mr. Eyles, also to endeavour to bring their collections as soon after nine in the morning as possible, as it will take some considerable time to arrange them." We think Mr. Dix's hope that the exhibition will be successful, will be fully realised, for we know of many who will exhibit, and who will detail most interesting information relative to the production of these varieties.

—— The following, from a correspondent, merits attention:

"Few things could have given more satisfaction than the announcement of the show of Tricolor Pelargoniums. The raisers and the public are alike anxious to know what is in existence. This show will afford the best possible opportunity of taking notes and assessing the plants at their relative worth to others. The information asked from the raisers about the history of these plants and the probable cause of their origin, will also have a specific value.

"There is one point that further information should be given upon, and that is the manner of judging the plants. The awards will carry great weight, and have a large money value, and it would be wise to appoint a special jury for the occasion; at least if several extra judges were appointed to act with the Floral Committee it would probably afford more satisfaction to many as well as—A Provincial."

WORK FOR THE WEEK.

KITCHEN GARDEN.

When the ground is not too wet the hoe should be kept in use: in some instances the appearance of weeds will sufficiently indicate the necessity of this; but even where such is not the case, this implement, or small three-tined drags, should be employed to stir the soil frequently between the rows of young crops. *Asparagus*, let those who would have it first-rate see that plenty of manure or half-rotted vegetable matter is dug into the alleys forthwith. *Celery*, prick-out, and a few trenches for the earliest may now be prepared, using plenty of manure; for to have it fine, it must be planted almost entirely in dung. *Carrots*, weed, and also *Onion*-beds as soon as the seedlings can be taken hold of. Those who are short of hands will find this the best economy. Examine the various *seed-beds*, in order that any defect may be made up as much as possible. *Lettuce*, transplant from the seed-beds before the plants become too large, and sow successions; the Paris White Cos and the Malta Cabbage Lettuce should be more especially cultivated for summer use. *Peas*, stick them as soon as they are earthed up when a little above the ground, and sow successions, with Round *Spinach* between the rows, if space for the latter be not found elsewhere. *Rhubarb*, keep down all blossom shoots from both this and *Sea-kale*, and the latter should now have the superfluous shoots thinned away, about four or five to each stool are sufficient.

FRUIT GARDEN.

Proceed with the disbudding of Peach, Nectarine, and Apricot trees, taking care not to wound the bark of the branches at the base of the shoot; a knife should generally be employed. The blossoming being over, temporary copings may be removed, and syringing commenced. The aphis must be sharply looked after and destroyed as it appears by means of tobacco dust. Hoe and weed Strawberry-plantations, and lay grass or other substance between the rows to keep the fruit clean and the ground moist.

FLOWER GARDEN.

In order that half-hardy flowers may be induced to make rapid progress when planted out it is absolutely necessary that those taken from in-door protection undergo a hardening process for at least a week. To be well established in their pots and well hardened is to insure success. Many persons, however, in fact the majority, cannot command frame or pit room sufficient to receive a host of potted Verbenas, Calceolarias, Heliotropes, Petunias, Fuchsias, and Pelargoniums, such, therefore, cannot pot off stock singly. The next best plan is to prepare some raised beds in the kitchen garden with old vegetable mould light and sandy, and to transplant, or as gardeners term it, to prick-out the struck cuttings from the store pots into these beds about 3 inches apart, in fact, so that they can be taken up with a trowel with a ball of earth; they should have hoops and mats or some covering at night, and in bad weather all day. In the third or last week in May they may

be transferred to their destination, removing with good balls of earth. Tender Roses that have suffered from the effects of the past winter will now require to be pruned. Standards would likewise be much improved by giving them a good soaking with dung water; it is best applied in cloudy weather. All vacant beds in the flower garden should be again dug up or raked over, to be ready for the reception of the plants, which should be put in whenever the weather is suitable. Such herbaceous plants as Pæonies, &c., that soon will come into bloom should be tied up. Divide and transplant Hepaticas and strong plants of double Scarlet Lychnis, or take off some cuttings close to the root, and place them in a mild frame-heat in small pots, these will soon strike root, and will be fit for planting out in borders. Attend to the watering of lately-planted shrubs if they require it. As Crocuses and other bulbs will now be on the wane, patches of biennials which have stood the winter may be planted close beside them; when the annuals are decayed the bulbs, if necessary, may be removed at the same time.

GREENHOUSE AND CONSERVATORY.

We would again urge the propriety of weeding out all extraneous or fading plants from the conservatory and other plant-structures, better destroy inferior stock than suffocate the good. Where a system of high cultivation is carried out, crowding will assuredly defeat the end in view. Centradenias now exhausted with flowering should be shaken out of their pots and repotted. Fibrous loam and fibrous peat soil, with charcoal and coarse sand, make an excellent compost for them. Make cuttings of them as soon as suitable young wood can be obtained. Calceolarias will now be coming into bloom, they should have their flower-stalks tied out and plenty of room afforded them. They will now begin to form objects of much attraction in the greenhouse, but, above all, see that they are perfectly free from aphides before their flowers expand. Pelargoniums now begin to claim much of our attention. See that every leaf is perfectly clean, and that the branches and trusses are properly supported with sticks. Water freely, and occasionally with manure water. Have an eye to the propagation of stock for succession or winter-flowering in due time. Secure cuttings of such plants as Brugmansias, Clerodendrons, Eranthemums, and those useful winter-flowering plants Euphorbia jacquiniæflora and Geanera bulbosa. Those who have one house in which to grow the stock of Orchids must make a compromise in point of temperature between that of the hot and moist valleys or shady woods of the east, and those from the western hemisphere, which inhabit high and airy situations. To accomplish this we would advise a very free circulation of air during the earlier part of the day, and even a little all night, if possible, accompanied with a great amount of atmospheric moisture, and to accommodate with the least sacrifice, such as Aërides, Saccolabiums, Dendrobiums, &c., we would shut up a considerable amount of heat very early in the afternoon. All means under the control of the cultivator should, in fact, be brought into active and vigorous operation at this season. The plants which are beginning to expand their blossoms should be removed into a warmer but much drier atmosphere; indeed, many of the species with slender flowing-stems should be similarly located to prevent their damping off; those in baskets, or on blocks of wood, should never, at this season, be allowed to become perfectly dry. Every care should be taken to promote the extension of the roots and to preserve them, for on this depends the strength of the flower-stalks, and, of course, the ultimate beauty and perfection of the plant.

PITS AND FRAMES.

Harden-off tender annuals and other plants for the flower garden, and continue potting-off annuals and struck cuttings as they require it, putting in cuttings of scarce sorts for store. If cuttings of choice rock plants, such as Phlox setacea, nivalis, subulata, verna, procumbens, amœna, &c., with Saponaria ocymoides, Onosma taurieum, Alyssum saxatile, Iberis sempervirens, &c., are put into prepared cutting-pots in sand, placed in a mild frame heat and treated as Verbena cuttings, they will soon strike root and be fit for planting out, or potting-off, as may be required.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Sowed successions of Peas, Broad and Kidney Beans, and Scarlet and White Runners out of doors, protecting the Peas and Beans, especially from their natural enemies; but after this season the feathered tribe trouble us less. We have a fine lot of Kidney Beans in boxes to plant out under a little protection, as in a bed intended for Celery, to succeed those knotting their bloom-buds, which will again succeed those bearing profusely. A syringing with clear soot water overhead after a hot day, we believe helps to invigorate the plants, and keeps insects of all kinds away from them, and the keeping insects away is a much more profitable affair than driving them away, or destroying them. In all cases prevention is better than cure, and cleanliness, plenty of air, a temperature at night much lower than the daytime, so as to give the plants rest, a quick eye and nimble fingers are better every way than dealing much in filthy mixtures, which less or more will have to be used, if insects are allowed to become too numerous.

We mentioned some time ago that we had been little troubled with *green fly* on forced Strawberries for years, but since making that statement we have had a little fly on every batch since wherever they were placed, whether in pit, house, or orchard-house, and even on Saturday, discovered some on pots still standing out of doors. As they generally appeared on the young leaves in the crown, and if not removed by the fingers, would attack the flower-stalks; in some instances, besides thus removing them, we have had to smoke, but as they appeared on nothing else in the same place it looks as if eggs had been deposited on these plants late in the autumn, and that they had been hatched into vitality when they had received the necessary heat under glass. Drawing the fingers along such young leaves and flower-stalks, and then syringing with clear soot and lime water, or both united, is a quicker and cheaper process than smoking with tobacco, &c. We dislike smoking with tobacco after the fruit has begun to change colour, as we think the flavour of the tobacco hangs a long time about it.

Before this is printed, we hope, if the weather continues so fine, to give a good manure watering to Cauliflowers, Cabbages, forward Peas, &c. After so much rain, there is little likelihood of the drainings from the dunghill, or the farmyard being too strong for such purposes. When strong water cannot be obtained from the stable or cow-house undiluted with water, it should have four or five times the quantity of water added before using it.

Disappointments.—We instanced lately colouring seeds with red lead for keeping birds from them, and so far as we can see it is effectual in every case; small seeds and even large seeds, as Peas included, in no case have we seen them touched; but, then, that is no security against the seedlings being preyed upon. We sowed some rows of Lettuces very thinly, intending to let them perfect themselves in the rows without transplanting, and they showed well, but not one is now visible, and with all our examining we could not find the trace of a slug or snail, as means had been taken to keep them away. Birds, no doubt, were to blame, and we would not have been so sure but for the following fact:—The first sowing of out-door Carrots was just beginning to show, but instead of advancing they seemed to get out of sight more and more. Lest slugs should assail them at night, lime and soot were thrown thinly over the piece, but still with no manifest advantage, and we could find no trail of an enemy, and the ground being dry, no mark of birds; but on looking at this ground between 3 and 4 A.M. we had the satisfaction of seeing three brace of partridges marching up and down the rows, and nipping up every green thing. We have no doubt that in some such cases the seedsmen bear the blame, when the seed was all right enough.

FRUIT GARDEN.

We have already alluded to Strawberries and green fly. Otherwise we have never had them show stronger, and hardly a blind one among those in pots, and after such a wet dull autumn as last year. Partly on that account, our plants as a whole were not so strong in the autumn as usual. Two thoughts have just struck us, and we would wish them to be ventilated among our brethren. First, whether it is not possible to have our Strawberry plants for forcing *too strong* before the autumn—that is, that there may be too much foliage to permit of perfect ripening of the fruit-buds; and secondly, whether the fullest exposure to the sun after potting may not in bright autumns be carried to an excess? The plants in the open ground are also showing very well.

The chief work has been thinning, disbudding, and watering; and the orchard-houses have required the latter liberally. During the brightest days we threw with a syringe water just coloured with whitening over the glass, merely spattering it, just to break a little the force of the sun's rays, and prevent the

plants drying so quickly. This would be all washed off by the first shower, and if dull days should come without rain, the most of it would come off by drawing a large hair broom over the glass. Such spattering from a syringe would be done to a large extent of glass in a few minutes, and it is a useful practice especially when, as in the present case, such bright weather follows after dull drizzling weather. This is the quickest and cheapest mode we know of for giving a slight temporary shade.

ORNAMENTAL DEPARTMENT.

The fine weather after the rains has made the grass grow far beyond our reach, and in such cases, for removing Daisies, &c., our daisy knife has been very useful, making a large space green in a short time. Our chief work, besides attending to cuttings, potting, and watering, has been fresh arranging verandahs, conservatory, &c.; taking Azaleas, Cytisus, &c., to the coolest places where a little shade can be given; placing Scarlet and other Pelargoniums where they would have more light, air, and coolness; moving Fuchsias where they could have plenty of air and room to grow. All these matters require much forethought where a large extent is to be made ornamental and there are no houses or pits especially for such preparatory purposes; but every house has to serve many purposes besides supplying fruit as the chief object. Under such circumstances plants grown in shade will be apt to become drawn a little, do what you will, a matter sometimes lost sight of when much is wanted with very inadequate means, and when comparisons are made between results so obtained and results in different circumstances, where a house can pretty well be devoted to one definite object. This is a subject which some most intelligent, deserving, successful gardeners have wished us to advert to prominently; but we would rather that some other coadjutor or correspondent would give it attention, and allow the matter to be fairly ventilated for the benefit of all parties.

These general fresh arrangements are not desirable, but at times they can scarcely be avoided. It is well when a plant past its best can be removed and be replaced by another, without any general clearing out; but the latter plan has this advantage at times, that an old plant-house may be made by fresh arrangements to look altogether a different house. As in our case, hitherto we have had a large space under glass to make ornamental, which we could only do when all danger from frost was over. Such a fresh arrangement two or three times a-year was almost indispensable, besides the temporary changes referred to. Thus with other minor matters, the Azaleas not removed have been placed in the shadiest part of the conservatory, and the Camellias, about over, have been taken to the late vinery, and as the chief attraction besides were Salvias, Cinerarias, and Primulas, these, though some are very good still, yet being past, instead of coming to their best, were all removed, the house, stage, &c., well washed, a fresh arrangement made with the Azaleas, as above alluded to, and florists' fancy Pelargoniums, Scarlet Pelargoniums, Fuchsias, Lantanas, &c., so that the house has an entirely different appearance from what it had a few days ago. Even with no change of material, a small house may be made very attractive by so changing the arrangement of the plants, as to present a different appearance. When the amateur enters his small house, and finds every plant in its accustomed place, the feeling of monotony will creep over him, which would be dispelled even by the interest awakened from having to seek for his favourite plant under a fresh arrangement combined with other plants. —R. F.

COVENT GARDEN MARKET.—May 8.

We have no alteration much to note here, prices remain nearly the same. A large quantity of new Potatoes from Lisbon has eased the market, and we daily expect our West of England growers to commence sending. Hothouse fruit far in excess of the demand.

TO CORRESPONDENTS.

Books (*H. G.*).—We intend publishing such a work as you mention next spring. The botanical part of the Dictionary you mention has not been published in a separate form.

Royal Horticultural Society (*N.*).—If you write to J. Richards, Esq., Assistant Secretary, Royal Horticultural Society, South Kensington, he will readily send you printed particulars You can then decide for yourself whether you will be a two-guinea or four-guinea Fellow. There is not a sufficient number of pomologists to support a journal devoted to their favourite pursuit.

Stalks of Bunches of Grapes Shanking (*Grapes*).—We think that sixty bunches from such a small house, 10 feet long, was rather over-cropping. The shrivelling-up of some of the bunches is owing to the excessive wet of the season, the unprotected state of the stems in winter, and rather too moist an atmosphere inside the house. Give more air.

Insects (*Subscriber*).—The "reptiles" at the roots of your Peas are a species of snake millipede, Julus pulchellus. Strew some rape-cake dust along the bottom of the drills, then sow the Peas, and cover them with the same kind of dust before covering with earth.

Tea-scented and Noisette Roses (*Rosamunda*).—To have these bloom in August they should have the necessary pruning at once, and should be placed out of doors in an open and sunny situation, the pots being plunged in coal ashes or other material. Allow them plenty of room, and top-dress the surface of the soil in the pots with rich compost. They should be well watered and syringed on the evenings of hot days. You may plant them out of the pots in good, rich, deeply-dug or trenched soil, where they will grow more vigorously; we would do so now, pruning them in a few days hence. It will be necessary to have a canvas or other awning in readiness in order to retard the blooms, if too early, and also to protect them from rains and excessive drought and winds. If you grow them in pots, they will be more readily removed and placed in a cold pit if it be necessary to forward them.

Walker's Stove.—"E. B. B." wishes to be informed if any of our readers have used this stove in a plant-house, and if so, with what results.

Glazing a Small Span-roofed House (*A. B. C.*).—1, For such a small span-house, 15 feet long, one end against the gable of a dwelling-house, with side glass above the wall 3 feet in height, altogether about 5 or more feet in height, and supposing that the house at the ridge is from 9 to 10 feet in height, you need not be in any doubt as to the quantity of glass wanted, by taking the square feet of the roof, end, and sides, deducting the spars for the sash-bars. 2, You will obtain very good glass for such a purpose at about 16s. per 100 feet, cut to the size you want; but if you wish to be secure, we would advise giving about one-third more for 21-oz. sheet glass. 3, You would build such a house most economically by having two or three ventilators in the side walls, and having the whole of the side glass, and the roof glass fixed. You would want one ventilator on the roof, close to the gable of the house now standing, and another over the doorway, and then in very warm weather you could open the door. For such a house we would use squares from 18 inches wide and 12 or more in depth, and rafter sash bars 1¼ inch wide and from 3¼ inches deep, placed so as to receive the 18-inch-wide glass between the rebates. 4, Such span-roofed houses give more light than lean-to's, but of course they are much colder in winter, and require more fire to keep them warm. Where a wall for a back already exists and costs nothing, we would be strongly disposed to have a lean-to with a fixed roof. Very fine things have been grown under lean-to's, and they require much less fuel to keep them warm. Where a wall has to be built, then we would prefer the low walls at the sides of a span-roof, as the glass and wood will be cheaper than brick. Of course the aspect is something. If a lean-to you should have the sloping glass facing south, south-east, or south-west; with the ends of the house pointing north and south or that way, you would be sure of plenty of sun all day.

Bees in Conservatory (*E. M. B.*).—The best and only method that we know of preventing bees from entering a conservatory is to have the openings covered with hexagon netting.

Taking up Tulips, Anemones, and Ranunculuses after Flowering (*Idem*).—The bulbs and roots of these plants may be taken up after flowering and when the foliage turns yellow, as they are then perfected. They may be dried a little on a shelf in a cool airy shed, and when dry stored away in sand. It does not injure them much, if at all, if they are mature when taken up, and they are planted early in autumn.

Pricking-out Auricula Seedlings (*E. F. W.*).—You may transplant, or rather prick off, the seedlings sown this spring when they are large enough to handle. A north border will be a suitable place for them. Do not plant too much under the shade of the wall or hedge Auriculas like a moderately rich and rather strong loam; but they will thrive in a light soil.

Blossoms of Orchard-house Trees Falling (*A Subscriber*).—We hope that you will succeed better next season. Do you lift your trees in pots—that is, to break or remove the roots that have gone through the pots, say in the beginning of October? The dropping of the blossoms we attribute to one of two causes—want of ripeness of wood in autumn, or allowing the pots to become too dry. We have had no dropping of blossoms, but many of the blooms of Cherries were defective. We attribute this to the trees standing thickly in the house last autumn. We would have liked them out of doors after September for a month or two.

Mealy Bug.—Mr. Cooke, gardener, Gatcombe Park, says that he has found two fumigations with Collyer & Roberts's "Tobacco Tissue" effectually removed this pest.

Camellia-bed (*Flora*).—You may plant Ferns among the Camellias; but whether the Ferns succeed will depend upon soil, aspect, and treatment. The leaf enclosed is of Populus alba, var. canescens.

Bleached Leaves (*G. N.*).—They will not stick to the paper if washed thoroughly in water after removing them from the bleaching liquid. Oiled paper may be also used.

Soil (*Beta*).—The sample enclosed, with the admixture of sharp sand, will do for Begonias. Cocoa-nut fibre refuse is useful where you cannot obtain peat.

Planting Forced Strawberry Plants (*Subscriber*).—We would plant out every potted Strawberry plant that showed fruit. You will endorse our opinion next year.

Top-dressing Vine Borders (*T. W.*).—The best time to top-dress Vine borders covered with tarpaulin during the winter months is early in summer; then, upon the removal of the covering, a top-dressing from 1½ to 3 inches thick may be applied. Inside Vine borders should be top-dressed in winter; but we prefer doing so immediately after the house is cleaned and put in order for another year; any time, however, from the fall of the leaves to the recommencement of growth, is a good time to top-dress Vine borders. We prefer extending Vine borders early in autumn, or when the leaves turn yellow; but it may be done from that time until growth recommences.

Gesneras not Thriving (*A Novice*).—It is hard to tell what could cause the evil of which you complain, as you do not furnish us with any particulars. We are inclined to think, from the description you give of their present appearance, that they are infested with insects, but what these are we are unable to form an opinion. Send us a leaf or two.

Greenhouse Vinery—Burning Sulphur in (*Sabrina*).—1, We can have no objection to your substituting hot water for the flue for such a house, 20 feet by 12, only if the flue is sound, fresh, and works well, we would think twice before we made the alteration. You will most likely find that you will effect no saving in fuel. 2, We knew an experienced gardener that burned sulphur to kill fly on Cinerarias once, but it was a lesson for the future. We are surprised that what your predecessor did in this way in 1864 he repeated in 1865. No doubt the little fruit was spoiled, leaves shrivelled, &c. Our only surprise is, that the Vines did not suffer more from such inflictions. Your accidental burning of wood in the house was a less evil, though that would be very injurious, but lessened in its effects by the leaves becoming ripe before the accidental burning. No growing plant will stand the fumes of burning sulphur. When we have cleared out a house we have often burned sulphur, covered with a thick layer of damp moss, to destroy not only moulds like your predecessor, but every living thing. No plants will stand this sulphur-smoking except those that are deciduous, and even these, as Vines, Peaches, &c., will be injured, unless the wood is well ripened, and at the rest period. 3, You must be content with less. Let the Vine roots have the border or the most of it. The Strawberries not only take away much of the richness of the soil, but the soil is kept cool beneath them with their thick shade. A row or so in front would not be so much, but the thick plantation of Strawberries will be sure to injure the Vines, and will naturally cause them to root deeper than would be desirable. 4, Your Vines must have a strong constitution to pass through so many disasters, and still be moderately vigorous, though not fruitful, and before you take the following advice, we would ask a good neighbouring gardener to see them, as we base it chiefly on the supposed fact that the stems of the Vines will have somewhat suffered. We would select on each Vine, near the base, the best and strongest shoot that now is growing, as you have used no fire, train that carefully without stopping, stop all the shoots that show fruit at one joint beyond the fruit, and stop all the other shoots left, thinning them out moderately, but leaving enough to keep up the free growth. As the one unstopped shoot grows, remove all the fruitless shoots as it passes or comes up to them. The object of doing this is to throw all the strength of the Vine gradually, but at length thoroughly, into this fresh young shoot. For this purpose, until autumn allow the laterals on this shoot to grow a joint or two before stopping them, and allow none anywhere else. As soon as the fruit is cut, take out the old shoots, or stems, and give fire heat in the autumn thoroughly to ripen this new shoot, and commence with that next season. Meanwhile clear out the Strawberry-border, remove what surface soil you can until you reach the Vine roots, and top-dress with 3 or 4 inches of rich fresh soil. Mulch with horse-droppings.

Rose Tree Bark Eaten—Destroying Aphides in the Open Air (*A. B. A.*).—We should think the bark is eaten from the shoots of your Rose trees by beetles of some kind, but what these are we are unable to tell. You may destroy the aphis in the open air by syringing the trees infested with tobacco water from the tobacconists, diluted with six times its volume of water.

Diseased Pear Leaves (*C. M.*).—The blisters, as you term them, are elevations caused by the vegetation of that pest, the parasitic fungus Roestelia. If only a few leaves are affected pick them off without delay and burn them. Do this immediately with every leaf you see similarly attacked, for the spores are diffused and every one of your Pear trees will be similarly scourged. If too many leaves are affected to permit of their being removed, dust flowers of sulphur perseveringly over the leaves, and this will have to be repeated every season until the fungus is extirpated.

Nitrate of Soda and Common Salt (*A Reader*).—If mixed they will not have any chemical action on each other. One pound of the mixture to each 30 square yards of your grass land will be sufficient. We should apply it immediately. (*Artificial*).—You will see by the preceding answer how much to apply to 30 square yards; the same, namely, as of the mixture with common salt. Do not let it touch the leaves of your cultivated plants.

Vines Fruiting only at the Ends of the Canes (*W. B.*).—We think there are two very likely causes—namely, that the roots of the Vines have gone down far from the surface, and that would help the second cause—an imperfect ripening of the wood. In the latter case give little water after August, and dry heat from fires in autumn. If the roots are deep and the foliage large, we would select one or two shoots to each Vine, grow them without stopping, and let these shoots bear next season. This latter advice was taken partially last season in several circumstances, and there was scarcely a bunch on the spur-pruned, but plenty on the rod-pruned Vines.

Planting a Flower-bed (*B. B, Evershot*).—Both your plans would do very well, but we prefer the second, as being more simple and lasting better. The ground-carpeting with white Petunias will not hurt the Gladiolus, if the Petunias are planted between the rows of Gladiolus and are not allowed to grow too rampant. We presume that the Gladioluses are chiefly scarlet; if they were chiefly light-coloured a carpeting of pink Saponaria calabrica would be very effective.

Cutting Down Heaths (*H. D.*).—You may cut down the Heaths to within a foot of the ground, and in all probability they will start from the bottom, but it is not a good practice, as in all cases that have come under our observation they are impatient of much cutting back. We should remove them and plant fresh ones. The following are compact growers—Erica vulgaris decumbens, E. Hammondi, E. vagans carnea, and E. tetralix intermedia.

Azaleas not Flowering (*C. W.*).—Repot at once the Azaleas that have not flowered and are growing freely if they require it, giving them but a moderate shift, and employing a compost of two-thirds sandy peat and one-third turfy loam, with good drainage. The plants should be kept rather close, and syringed overhead morning and evening, the soil being kept no more than moist for a few days, until the roots are working in the fresh soil, then water freely. When the growth is complete give abundance of air and light, and we think they will set their buds well, after which keep cool and airy.

Planting a Sloping Bed (*An Amateur, Oakham, Rutland*).—You do not say what the form of your bed is, but we presume it is a rectangle or parallelogram. In that case you may plant it in ribbon-border fashion, which, with the materials at command, we would dispose of as follows:—1st, a row next the walk of Bijou Pelargonium; 2nd, Tom Thumb; 3rd, yellow or orange Calceolaria; 4th, Christine Pelargonium; 5th, Stella; and 6th, yellow Calceolaria. Had you Cerastium, Lobelia, and Golden Chain Pelargonium our advice would have differed materially; but being restricted to the plants named, you will find the bed or border look very well with Scarlet Pelargoniums, but infinitely better if you add Calceolarias.

Exterminating Ants (*A Sufferer*).—We can only repeat what we have repeatedly stated, that guano sprinkled over their haunts will drive them away, and ammoniacal liquor from the gas works poured into their nests will speedily cause them to migrate.

Orchard-house Tree Leaves Scorched (*F. T.*).—The leaves sent are scorched through placing sulphur upon hot coal. The fumes of burning sulphur will destroy both animal and vegetable life, and its use along with tobacco for fumigation is to be avoided, as the remedy is more disastrous than the injury caused by the insects it is employed to destroy.

Name of Fruit (*F. W.*).—Easter Pippin or French Crab.

Names of Plants (*Burntwood*).—Alpinia nutans. (*T. B. Brossley*).—1, Selaginella cuspidata; 2, S. apoda; 3, S. cuspidata, two specimens; 5, Cheilanthes elegans; 6, Adiantum hispidulum. (*C. J. B.*).—Asplenium fontanum. (*T. Catchpool*).—Bromus secalinus, or Smooth Rye Bromie Grass; it is a native of England. (*Mrs. Crosland*).—Oxalis, species not determinable. (*P. C.*).—Amelanchier canadensis. (*P. M., Chelsea*).—1, Pultenæa, species; 2, Apparently a new plant. Please send again when more advanced. (*Ella*).—If the leaves are palmate, it is Viola palmata variegata.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 7th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE ORIGIN OF GAME FOWLS.

Great Britain is the only country in Europe which possesses the Game fowl. India and its islands are, probably, the original countries of the Game fowls, and still possess them. Game fowls are also to be found in Spanish America, probably imported thither from Manilla in the Philippine Islands. Persia and Asia Minor, or Syria, once had them, and the ancient Greeks and Romans were famous for their Game fowls; it is likewise said that the Romans introduced them into this country. With the ancient Greeks, the island of Rhodes was famous for its Red Game fowls, which were called the Rhodian Reds, and the island of Delos for its Silver-Greys, called the Delos Silvers. Some assert that Game fowls were indigenous to the British islands, and some call them a Roman importation, but it is strange, that if a Roman importation, Great Britain alone, of all the Roman European colonies, should have retained them. This would rather prove that they were originally natives of these islands, though they certainly rather bear the appearance of a tropical or Indian origin. However, they have probably been in this country since its occupation by the Romans.

It has been asserted that the Gallus Bankiva has been the progenitor of the Game fowls. I incline to the belief that the three original colours of Game fowls were those of wild original birds which had been reclaimed from a state of nature at some very early period, perhaps in India. The Gallus Bankiva is not fierce enough, nor strong enough, nor large enough to have been the original of our Game breeds, though Bankivas resemble the Black-breasted Red Game. They were, no doubt, the original from which sprung our Bantams, Game Bantams being very like them, especially the Black-breasted Red, though the Bantams are a little smaller than the Bankiva.

The Gallus Sonnerati, or Indian Jungle fowl, has been mentioned as the original of the Game, but in this breed the hen has neither the comb nor wattles, and the cock has the peculiar horny structure of the feathers, which show them not to have been the parent stock of our Game breeds, though they are fierce and spirited birds, and are used for cock-fighting by the natives of the East Indies.

The wild Gallus furcatus, or Forked-tailed cock, thoroughly resembles our blue-legged Red Dun Game, having the blue legs and blue dun breast and tail, and is red in the plumage, but the comb in this species is not serrated or lobed, and it has only a single wattle, and, therefore, differs rather too much.

Game fowls may probably have sprung from the mixture of all the three breeds named, with their own three original wild colours, as many good naturalists believe them to have done. I think, however, that the characteristics differ rather too much, and adhere to the belief that the original colours, which are still to be met with in India, as well as in Britain, were derived from birds reclaimed from the wild state in India or elsewhere at a very early period. Most Indian Game fowls are yellow-legged, but not all. The specimens lately exhibited by the late Mr. B. P. Brent, appeared to be the true Indian Game.

I have already stated that some breeders consider the Grey Game fowls to be a primitive or original colour, but brown of various shades is certainly the original colour in Game hens, and assimilates much the best with the colour of the earth, the foliage and bark of trees, and every natural object, which grey does not. Grey is the wild colour for sea birds, as brown is for land birds, and most good judges condemn grey as an original colour, and agree that the brown hens of different shades, and their red cocks with the greenish dark tails are the only true originals. The Greys, too, always incline much to breed back to the brown hens and red cocks, which shows that these are certainly the true original colours, and grey is often difficult to produce, as in the Game Bantam breeds. Grey is, therefore, most certainly not an original colour as some still erroneously suppose and assert.—Newmarket.

EPWORTH POULTRY AND PIGEON SHOW.

Although the meeting that took place on the 3rd instant was only the second Show that has been held under the management of the Epworth Committee, it proved itself fully equal to many other shows that have boasted a longer standing by many years. The entries on this occasion were fully double those of the year preceding, and anxious to meet the wishes of all supporters, the Committee had wisely connected with the poultry a show of dogs, that no doubt added much to the general attractions. It must be borne in mind that Epworth is a purely agricultural district, and therefore it formed a matter of agreeable surprise to find that the attendance proved nearly threefold that of last season. Everything went on most pleasantly, and the visitors were loud in their congratulations of the Committee. Public confidence appears to be now fairly enlisted in support of the exertions of the management, and several additional annual subscriptions were readily promised on the spot. The day proved a most enjoyable one, the weather being bright and sunny, nor did a single spot of rain fall in the locality of the show-yard during the whole time the Show was open, although at one time the subject of anxious apprehension was that a storm was impending.

The exhibition coops used were those that for many years past have done like duty at the Thorne Show, and, considering the breeding season being now at its height, it was a very remarkable feature that so few pens were vacant.

The quality of the poultry shown was in nearly every class first-rate, and the display of *Pigeons* included large entries from many of our most spirited exhibitors. This evidently formed a very popular portion of the Exhibition, and several very uncommon varieties of Toy Pigeons added most materially to the general interest. Bees, busily working in glass hives, formed another attraction, and the display of fresh butter and eggs was remarkably good. On the poultry pens were arranged a very creditable collection of Parrots and other foreign birds in excellent plumage, whilst Canaries and other singing birds natural to our climate were shown in abundance. A few very capital *Rabbits* were also exhibited. It is a most satisfactory duty to record that not a single accident or mishap occurred in the carrying out of so varied an exhibition, and we especially noticed that within less than an hour from the time of closing every pen was carefully repacked and ready for transit homewards by the next ensuing train. We were informed by the Honorary Secretary, Mr. Hudson, that by the time of next year's show additional railway accommodation will be secured to Epworth, which will, no doubt, entice many amateurs to enter the lists who were deterred from so doing on the present occasion, on account of the distance of the Show from the nearest railway station.

The care taken of the poultry and other live stock on the ground was all that could be desired, and we entertain but little doubt that with continued perseverance on the part of its promoters, the Shows at Epworth in coming years will prove to become most important agricultural meetings.

Spanish.—First, T. Rogers, Walsall. Second, Rev. W. J. Mellor, Colwick Rectory, Nottingham. Commended, T. E. Hitchen, Sheffield.

Dorkings (Any colour).—First, Mrs. Jefferson, Epworth (Grey). Second, G. Oldfield, Epworth.

Game (Any variety).—First and Second, Messrs. Sales & Bentley, Crowle. Highly Commended, J. R. W. Harrison, Spalding (Black Red). Commended, W. H. Wheeler, Carlton, near Nottingham (Duckwing.)

Cochin-China (Any colour).—First, J. H. Dawes (Cinnamon). Second, Rev. W. J. Mellor (White). Commended, W. H. Wheeler (Partridge.)

Brahma Pootras (Light or Dark).—First, Withheld. Second, Rev. W. J. Mellor.

Hamburghs (Gold or Silver-spangled).—First, Messrs. S. & R. Ashton, Mottram, Cheshire (Golden). Second, C. Gravil, jun. Commended, J. F. Loversidge, Newark (Golden).

Hamburghs (Gold or Silver-pencilled).—First, W. Bearpark, Ainderby-Steeple, Northallerton (Silver). Second, Withheld.

Game Bantams (Any colour).—First and Second, R. Bentley, Finningley Park (Black Red, Duckwing). Extra Second, H. Cawood (Black Red). Highly Commended, J. H. Dawes (Black Red). Commended, T. Rogers, Walsall; C. Gravil, jun., Thorne.

Bantams (Any other variety).—First, T. Burgess, Yorkshire (Black). Second, Messrs. S. & R. Ashton (Silver-laced). Highly Commended, R. Bentley (White Japanese); T. C. Harrison, Hull (Gold-laced); Messrs. S. & R. Ashton (White).

Any other Distinct Breed or Farmyard Cross.—First, Mrs. J. Cross, Brigg (Crève Cœur). Second, Withheld.

Game Cock (Any colour).—First and Second, Messrs. Sales & Bentley. Highly Commended, E. Brough, Leek (Brown Red); W. Bearpark, Northallerton.

Cock (Any other breed).—First, J. H. Dawes (Buff Cochins). Second, T. Rogers, Walsall.

Hen (Any other breed).—First, Messrs. S. & R. Ashton (Golden-spangled) Second, C. Addey, Epworth.

Guinea Fowls.—First, T. C. Harrison, Hull. Second, J. H. Dawes.

Turkeys.—First, Rev. W. J. Mellor. Second, R. Bentley. Highly Commended, Mrs. S. A. Wroot, Levels.

Geese.—First, — White, Thorne. Second, Rev. W. J. Mellor.

Ducks (Aylesbury or Rouen).—First, — White (Rouen). Second, J. W. Harrison, Spalding (Rouen.)

Ducks (Any other Breed or Cross).—First and Second, T. C. Harrison (Pintails, Grey Call Ducks). Highly Commended, J. W. Harrison (Wild Ducks.)

Selling Class (Any variety).—First, T. Rogers, Walsall (Spanish). Second, G. Yates, Thorne (Black Red Game). Third, Messrs. S. & R. Ashton (Silver-pencilled Hamburgh).

Extra Prize for best pen of Poultry (a Painting of Game Fowls).—Messrs. Saltmarsh & Bentley, Crowle (Brown Red Game.)

PIGEONS.

Carriers.—First, H. Yardley, Market Hall, Birmingham. Second, J. W. Harrison. Commended, H. Brown, Sheffield; J. R. Jessop, Hull.

Pouters.—First, H. Yardley. Second, J. Taylor, Newark. Highly Commended, H. Brown. Commended, T. Burgess, Brighouse.

Tumblers (Any variety).—First, T. Statter, Hull. Second, H. Yardley. Highly Commended, H. Cawood (Beards); T. Burgess (Almonds).

Fantails.—First, T. Elrington, Woodmansey, Beverley. Second, H. Yardley. Highly Commended, H. Yardley.

JACOBINS.—First, F. Key, Beverley. Second, H. Yardley.
BARBS.—First, Rev. W. J. Mellor. Second, H. Yardley.
NUNS.—First, T. Burgess. Second, H. Yardley.
TRUMPETERS.—First, H. Yardley. Second, C. Addey. Highly Commended, C. Gravil, jun.; C. Addey.
ANY OTHER VARIETY.—First, H. Yardley (Ice Pigeons). Second, F. Wait, Sparkbrook (Ural Ice). Highly Commended, Mrs. Cross, Brigg; H. Yardley; F. Wait (German Toy); T. Burgess; J. W. Thompson, Hull (Friezelands).
SELLING CLASS (Any variety).—First and Second, F. Waitt (Hyacinths, Lahores). Third, T. Statters, Hull (Tumblers). Highly Commended, H. Yardley. Commended, H. Yardley; J. W. Harrison (Pouters).
Extra Prize for best pen of Pigeons.—T. Elrington (White Fantails.)

CAGE BIRDS.

CANARY (Yellow).—*Cock.*—First, Miss A. Dundas, Epworth. Second, Messrs. Smith & Naylor, Epworth.
CANARY (Buff).—*Cock.*—First, Messrs. Smith & Naylor. Second, J. M. Haycroft.
CANARY (Green or Variegated).—First, Messrs Hanson & Wagstaff. Second, C. Peart, Crowle. Commended, Miss Read, Epworth.
GOLDFINCH.—*Cock.*—First, C. Chappel, Thorne. Second, G. Yates. Highly Commended, J. Boyes, Epworth.
LINNET.—*Cock.*—First, Master R. Maw. Second, Master W. H. Butterfield, Epworth. Commended, R. Jackson, Wells.
ANY OTHER VARIETY OF CAGE BIRDS.—First, Miss Read (Parrot). Second, T. W. Dawson, Epworth (Goldfinch Mule). Third, W. Hebditch, Epworth (Thrush). Fourth, D. Daubney (Parrot). Commended, W. Riley, Crowle (Goldfinch Mule).

RABBITS.

ANY COLOUR.—First, C. Gravil, jun. Second, Messrs. Hanson & Wagstaff. Highly Commended, R. Stephenson, Beverley; C. J. Matthews, Epworth.
BUCK.—First E. Roberts, Thorne. Second, Messrs. Hanson & Wagstaff. Highly Commended, H. Yardley; A. Sales, Belton. Commended, E. Dimmock, Bull-hassocks.
DOE.—First, Messrs. Hanson & Wagstaff. Second, H. Yardley. Highly Commended, G. Lindley.

JUDGES.—*Poultry, Rabbits, Singing Birds, and Pigeons:* E. Hewitt, Esq., Sparkbrook, Birmingham, and J. Richardson, Esq., Thorne.

NEWCHURCH POULTRY EXHIBITION.

(*From a Correspondent.*)

THIS Exhibition was held in connection with the Newchurch Agricultural Show on the 29th of April, which, although the morning was dull and foggy, proved a beautiful spring day.

The pens were arranged in the left-hand corner of the Show ground. Some portion of the pens were two rows in height, but those placed below, by the good management of the Committee, were devoted to Turkeys, Geese, and Ducks. Great praise is due to the Secretary, Mr. Lonsdale, and the Committee, for their indefatigable exertions in performing their duties.

The number of entries was nearly one hundred, and although this may appear to some as being rather small, there were birds of as high merit exhibited as any seen at larger shows.

The class for single *Game* cocks, including all varieties, contained some first-class birds. The first prize was awarded to a magnificent Black Red, closely pressed by a splendid Brown Red. Both these birds are the property of C. W. Brierley, Esq., of Middleton, and were shown in first-rate condition. In the next class, for single *Game Bantam* cocks, the same gentleman succeeded in taking both prizes. In the class for Bantam cock and hen, all varieties competed, including Game Bantams. This class contained the most entries of any class in the Show, and was one of the best. The first prize was taken by a magnificent pen of Black, which was much admired, and exhibited in excellent plumage. A first-class pen of Black Red Game was second, closely pressed by a pen of Silver-laced Sebrights. Next to this came the class for Game cock and hen, any age or colour. Black Reds took the first prize, and Brown Reds the second. In the *Dorking* class there were but two entries, the first prize being easily won by a pen of rose-combed birds. The plumage of the cock in this pen was deficient, owing to his feathers having been picked by hens; but his companion was a first-rate pullet. In *Cochins* of any age or colour there was a magnificent display; in fact, this class was probably the best in the Show, Buffs maintaining the high position they so honourably deserve by taking both first and second prizes.

Black *Spanish* constituted but a poor class, and with the exception of the hen in the first-prize pen, the rest were only moderate. In *Brahma Pootras* some very good birds were exhibited, the hens in the two pens being of the real type of a true-bred Brahma. Of *Hamburghs* there might have been a better exhibition, considering the neighbourhood of the Shew. There were but three entries for Golden-pencilled. The prize birds were of fair average merit. Only one pen of Silver-pencilled was exhibited. The Golden-spangled hens were decidedly better than the cocks, and with the exception of the prize birds there was nothing to merit great praise; and in Silver-spangled there was little difference between the prize pens.

Of *Turkeys*, *Geese*, and *Ducks* there was a fair entry, the prize birds far outdistancing their competitors. Mr. Leech, of Rochdale, was the most successful exhibitor in these classes, by winning all the first prizes.

The Arbitrator deserved much credit for the careful and judicious manner in which he decided his awards, a list of which is appended.

SINGLE GAME COCK (Any age or colour).—First and Second, C. W. Brierley. Highly Commended, J. Foulds, Burnley; C. W. Brierley; E. Aykroyd, Bradford.
GAME BANTAM COCK.—First and Second, C. W. Brierley. Highly Commended, G. Birtwistle, Haslingden; F. J. Astbury, Prestwich.
BANTAM (Any variety).—First, W. A. Taylor, Manchester. Second, C. W. Brierley. Highly Commended, T. Birtwistle, Haslingden; Messrs. S. & R. Ashton, Mottram.
GAME.—First, C. W. Brierley. Second, E. Aykroyd. Highly Commended, C. W. Brierley.
DORKINGS.—First, W. A. Taylor. Second, J. Stott, Healy.
COCHIN-CHINA.—First, W. A. Taylor. Second, C. W. Brierley. Highly Commended, C. W. Brierley.
SPANISH.—First, J. H. Hardman, Rawtenstall. Second, T. Townsend.
BRAHMA POOTRA.—First and Second, W. Hargreaves, Bacup. Highly Commended, D. Haworth, Rochdale; J. H. Pickles, Todmorden.
HAMBURGHS (Golden-pencilled).—First, N. Marlor, Denton. Second, W. Parkinson, Staghills.
HAMBURGHS (Silver-pencilled).—Prize, W. Wilson, Laund.
HAMBURGHS (Golden-spangled).—First, N. Marlor. Second, Messrs. S. & R. Ashton. Highly Commended, N. Marlor.
HAMBURGHS (Silver-spangled).—First, — Smalley, Blackburn. Second and Highly Commended, J. A. Taylor, Manchester.
TURKEYS.—First, E. Leech, Rochdale. Second, T. Houlker, Blackburn.
GEESE.—First, E. Leech. Second, T. Houlker.
DUCKS (Aylesbury).—First and Second, E. Leech.
DUCKS (Rouen).—First, E. Leech. Second, T. Houlker.

Mr. Richard Teebay, Fulwood, Preston, officiated as Judge.

AYR POULTRY SHOW.

(*From a Correspondent.*)

THIS Show was held in connection with that of the Ayrshire Agricultural Association on the 1st inst., and was open to all Scotland. The day being very fine there was a large concourse of spectators, upwards of £150 being drawn for admission. The pens were arranged on stands in rows, enabling the visitors to see every bird in the Exhibition.

Of *Spanish*, the first-prize pen was the best I have seen for some time, the others were also good. The Grey *Dorkings* mustered strongly and were good, nor were the *Polands* and *Cochin-Chinas* less worthy of high praise. The *Scotch Greys* were a good class, but I was sorry to see some of the best pens passed over and inferior birds gain the prizes. The hen in the second-prize pen was far too small and showed Dorking toes, even the whole pen was much inferior to many a pen that never was looked at.

The following is a list of the prizes awarded:—

SPANISH (Black).—First, J. Sharp, Johnstone. Second, C. M'Intyre, Ochiltree Mills, Ochiltree. Third, A. Stewart, Coodham, Symington. Fourth, C. M'Intyre.
DORKINGS (Coloured).—First, J. H. Macnab, South Arthurlie, Barrhead. Second, Major-General Burnett, Gadfirth, Coylton. Third, J. Fleming, Kilkerran House, Maybole. Fourth, O. Fairley, Coodham, Symington.
DORKINGS (White).—First, J. Aitken, Paisley. Second, J. R. Aitken, Paisley. Third, P. Aitken, Loans, Troon. Fourth, J. Aitken.
HAMBURGHS (Golden-spangled).—First, J. Jardine, Millane, Kilmarnock. Second, R. Cunningham, Stewarton. Third, H. M'Latchie, Whitefordhill, Ayr. Fourth, R. Cunningham.
HAMBURGHS (Golden-pencilled).—First, A. M'Quater, Wallacetown. Second, W. Neilson, Johnstone.
HAMBURGHS (Silver-spangled).—First, J. Stewart, South Arthurlie, Barrhead. Second, J. Glass, Wallacetown. Third, B. Gairdner, Auchincruive Gates, St. Quivox. Fourth, the Hon. Mrs. Vernon, Mount-Charles, Ayr.
HAMBURGHS (Silver-pencilled).—First, R. Cunningham. Second, J. Paul, Glasgow. Third, J. Paul. Fourth, Countess of Eglinton and Winton.
COCHIN-CHINAS.—First, Countess of Eglinton. Second, R. Cron, Dalmellington. Third, G. Girdwood, Ayr. Fourth, R. Cunningham.
GAME.—First, A. Gibb, Wallacetown. Second, J. Macnab. Third, J. Sharp. Fourth, A. Morrison, Glasgow.
SCOTCH GREYS.—First, J. Paul, Glasgow. Second, H. Smith, North Woodside, Kilwinning. Fourth, J. Macnab.
BRAHMA POOTRA.—First, J. T. Gordon, Blackhouse, Ayr. Second, W. Young, Highfield, St. Quivox. Third, D. Davidson, Dalmellington. Fourth, J. Wilson, Peggrysshill, Ayr.
POLISH (or any other breeds not before mentioned).—First, Countess of Eglinton. Second, J. Glass. Third, Miss Fairlie, South Lodge, Ayr. Fourth, W. Dunlop, Stewarton.
TURKEYS.—First, Major-General Burnett. Second, J. Fleming, Maybole. Third, Miss E. Fairlie, Coodham, Symington. Fourth, T. Neil, Wes Doura, Tarholton.

BEES MISTAKING THEIR HIVES.

LAST Friday (April 26th) I moved nine stocks of bees into a house which I have lately built on purpose to receive them. The landing-stages are each 9 inches broad by 12 inches long; these I have left unpainted, though the front of the house is coloured green. The bees have entrance to their hives by holes three-quarters of an inch broad, by three-quarters of an inch deep. Although, however, three days have now passed since I moved the hives, the bees do not seem to be at all certain on which landing-board to alight, and in consequence they frequently make a mistake, and pay the penalty by being pitched overboard, in many cases dead. Yesterday alone, I counted upwards of a hundred dead on the ground. I should feel much obliged if you will give me your advice as to whether the slaughter will gradually diminish as the bees become more accustomed to their house, or whether I should in any way

distinguish the boards by painting or otherwise. I may add, that on the day after I moved the hives, I placed pieces of brick, wood, &c., on the stages, hoping in this way to stop the slaughter, but have not succeeded.—W. Leake.

[The entrances to your bee-house are probably somewhat near together, and similar in appearance. The mistake, and the contests resulting from them which you notice, will probably diminish in number as the bees become accustomed to their new abode; but it will be well worth while to furnish every alternate doorway with a distinguishing porch, which should be painted in such colours as may furnish the strongest contrast with that of the bee-house, and with each other.]

MEAD OR METHEGLIN.

Anticipating a good honey harvest this year, I have been searching all my bee books for the best receipt for making mead or metheglin, and finding scarcely two agree in recommending the same proportions, I venture to ask the advice of others more experienced than myself. Sir J. More says one gallon of water to one gallon of honey; Bevan, six gallons of water to one gallon of honey; Keys, one gallon of water to 3 lbs. or 4 lbs. of honey, &c.

Amid these distracting counsels to whom can appeal be better made, than to the Editors of The Journal of Horticulture? from whom we may, perhaps, receive accurate, and, therefore, valuable hints.—W. H. S., *Yaxley*.

[We shall be glad of advice on this point from any of our correspondents who had experience in the manufacture of mead. The following receipt is extracted from "The American Bee Journal:"—"Take 120 lbs. of soft water and 20 lbs. of clear strained honey. Mix them well in a kettle of suitable size, and boil down the mixture to 80 lbs., skimming it carefully while boiling, then pour it into a wooden vessel, and let it stand to cool. While yet lukewarm put in a pint of good stock yeast, stir thoroughly, and pour the whole into an oaken barrel (an empty rum or wine cask is the most suitable), which should be sufficiently large to contain ten gallons. The liquor remaining over is to be put in bottles and used to fill up the barrel or cask during fermentation. Now put into a small linen bag ¼ oz. cinnamon, ¼ oz. grains of paradise, ¼ oz. pepper, ½ oz. ginger, ¼ oz. cloves coarsely pulverised, and a large handful of dried elder blossoms. Suspend the bag by a string in the liquor through the bunghole, and place the barrel in a dry, airy cellar. Let the fermentation proceed during six weeks, keeping the barrel constantly full from the contents of the bottles. Then, after gently removing the bag, rack off the clear liquor into another cask, and close the bunghole lightly. Fermentation will still proceed moderately for six or eight weeks before the liquor becomes clear. It must then be carefully racked off into bottles and well corked. The lees remaining in the cask may be used in the preparation of an additional supply. Mead thus prepared will keep for years. It is of a clear amber tinge, and has a vinous taste."]

GOLD FISH.

In reply to "W. W. E. W." (see page 288), I wish to tell him that he will find that it is the trout that kills his fish.

Having had many kinds of fish together in a large glass tank, I have been able to observe their habits. I find that the common trout is the most ferocious of all the fish I have kept. It will not allow any other fish to approach its hiding-place. No sooner does the poor gold fish pass by than out the trout comes, savagely takes hold of tail or fin, and tears part of the fin away. A continuance of this treatment for a few weeks causes the tail part to decay, and a kind of fungus comes on the tail, which seems to be quite useless, and after some weeks the fish dies. Beetles and other water insects will soon cause its remains to disappear.

The trout is very cunning, and the only fish that seems to see through the glass sides of the tank, for as soon as I approach it darts under its rock, generally in the same place, although it has good places to hide near. It is quite a match for the stickleback, even if they are of the same size. I have seen these two fight like bulldogs. I may add I am compelled to keep the two species separate, by placing a wire netting across the tank, and then I have frequently seen master trout leap the fence.—Hawkins.

[Not only do trout in a pond, attack the gold fish as described by our correspondent that they do in a glass aquavivarium, but they eat the spawn and young fry of the gold fish. We have known gold fish thrive and breed in a pond similar to that mentioned by "W. W. E. W.," and they especially did so after water lilies and other aquatic plants were planted in the pond.—Eds.]

OUR LETTER BOX.

Malay Fowls (*J. C.*).—All that your friends have said about them is quite true, and to their characteristics we would add that we think them the ugliest of all fowls. The Rev. G. Ifastler, Stillingfleet Vicarage, York, is to you the nearest breeder of them. If you wish to keep an unusual variety, have Houdans, which have the additional merit of being excellent birds as layers and for table use. Mr. Baily, 113, Mount Street, Grosvenor Square, could supply you.

Malt Combs for Fowls (*John Tindall*).—You can only attain them of a maltster, and we do not know of one nearer to you than Ware.

Death of Dorking Cock (*A. B. C.*).—It is a very common thing for cocks to have dark combs when they have a difficulty in crowing; both proceed from cold, but death from this cause is lingering. Our own opinion is, that most of the diseases of chickens are caused by parasites, and the remedy for them is camphor. If the apparent worm in the roof of the mouth was one in reality, contact with camphor would have killed it. In these cases, stimulants are the proper treatment to relieve, and the free administration of camphor is the cure.

Diseased Liver in Fowls (*M. M.*).—The appearances you describe, wasting of flesh, and ulcers on the liver, are common in fowls that have been overfed to induce laying. Such treatment always induces dropsy or liver disease, and generally both before it becomes fatal. Where no undue feeding has taken place, it will result from age. Great layers do not last so long as those that are less productive. Potatoes have a tendency to produce liver disease; and great alternations in feeding, a high dietary for a time, and then a low one, lay the foundations of disease. We, however, believe you will find the sufferers are the aged among your stock.

Hatching Season—Spanish Fowls Losing their Feathers (*M. D.*).—You have not neighbour's fare so far as Brahmas are concerned. They have hatched well generally. Other varieties have not. Our experience of hatching this season is that it is a bad one to the present time; but better weather will give better hatching. We have wanted warm nights. Your Spanish fowls want grass, fresh earth, and green food. Lettuce is the best. They pick the feathers from a craving for something they do not get. After the feathers, they will eat the cock's face, and will strip each other. Cut large sods of growing grass with plenty of fresh earth to them, and supply them liberally every day.

Various (*J. S.*).—We are not sure you should not take away two of the cocks, you must take away one. Take away the hens that are sickly, give them castor oil, and rub the naked parts with sulphur ointment. Give them plenty of lettuce to eat, and let them have access to grass. Feed on meal only for a time. We cannot tell you the quantity of food fowls should eat, as it depends so much on that which they get in their wanderings. We are not friendly to allowancing poultry. Let them always eat till they leave off, but let no food lie about. They eat more at some times than at others. It will be, however, found that by feeding only while the birds will run after the food, less will be consumed than when a given quantity is allowed. The birds will also be in better health.

Tumours on Turkey (*S. F.*).—We have never cured the disorder you name. We have had it in fowls, and it has always increased till the birds died. None have ever laid while suffering from it, and on opening the body it was found to be a mass of disease, originating apparently with the organs of laying. The lumps we have seen were between the skin and the flesh, and could be moved. They contained a cheesy matter.

Food for Young Turkeys (*Subscriber*).—The best answer we can give is the following, from our "Poultry-keepers' Manual:"—"The first diet offered to Turkey chicks should consist of eggs boiled hard and finely minced, or curd with bread-crumbs and the green part of onions, parsley, &c., chopped very small, and mixed together so as to form a loose crumby paste; oatmeal with a little water may also be given. They will require water; but this should be put into a very shallow vessel, so as to insure against the danger of the chicks getting wet."

Carbonnier's Incubator (*Trent Side*).—We do not know where it can be purchased. If of any special merit it should be advertised.

Error.—At page 320, column 2, line 12 from bottom, we ought to have said "*not* prefer."

Preventing the Loss of Swarms (*S. S.*).—There is no mode of placing a hive and enticing bees into it which can be relied upon to prevent the loss of swarms. You may, however, drive an artificial swarm from your Ligurians, with the aid of one of your stocks of common bees, in the manner described by us in No. 271 of our New Series. This should be done as soon as both hives become crowded with bees.

Ligurians in Ireland (*Squib, Co. Kildare*).—The word "*sealed*" was accidentally omitted from the last line of our reply to your letter in our last Number. It should read thus:—"a tolerable quantity of sealed drone brood." We shall be glad to receive particulars of the future progress of Ligurians in the Emerald Isle.

Obtaining Artificial Swarms with Frame Hives of Different Construction (*J. C. A.*).—We fear that in your predicament we can only advise you to endeavour to follow the example of the distinguished editor of the "Extinswill Gazette" who qualified himself for writing on the somewhat abstruse subject of "Chinese Metaphysics," by turning to his Encyclopædia, perusing the articles headed "China" and "Metaphysics," and combining the information thus obtained. In other words, we recommend you to refer to Mr. Woodbury's articles on "Artificial Swarms," which appeared in Nos. 161, 162, and 217 of our New Series; then peruse the one on "Propagating Ligurians" in the Journal of the 11th ult., and combine and make use of as much of the information thus obtained as the circumstances and the extent of your apiarian attainments will admit. When using frame hives of different construction nearly all the advantages of frames are, of course, forfeited, and the easiest and simplest plan would probably be to treat them as common hives; but something may yet be done by cutting combs out of one set of frames and fitting them into the others. How much that "something" may amount to must, however, depend entirely on the skill of the bee-keeper.

From observations taken near London during the last forty years, the average day temperature of the week is 66.3°; and its night temperature 43.1°. The greatest heat was 89°, on the 22nd, 1847; and the lowest cold 30°, on the 18th and 19th, 1854; 20th, 1853; and 19th and 20th, 1856. The greatest fall of rain was 0.58 inch

PARIS UNIVERSAL EXHIBITION.

A DAY AT BILLANCOURT.

THE Seine as it flows past Paris forms several islands but little raised above the water level, and which are frequently inundated during the winter months. Of these Billancourt is one. When first it was proposed to devote it to a garden where the Parisian market gardeners should display their skill in cultivation, it was objected to the scheme that without an Imperial guarantee the cultivator could not risk the necessary labour against the overflow to be expected after the rains of last autumn. It was, therefore, eventually turned into a sort of "annexe" or adjunct for the agricultural machines, for which space failed in the main building.

The island is not unsuited either by distance or by natural features for this purpose, being flat and accessible to heavy machines, and adjoining the river. For some time the inundations which wearied the Commissioners have subsided, and something, though as yet extremely inadequate, has been done in the way of ornament. As to the valuable machinery it is safe under commodious sheds, and the climate is too fine to cause alarm.

The means of reaching Billancourt, however, have not been made so perfect as they may eventually become, and visitors would do well to be cautious how they use them. One of the Parisian papers, *L'Epoque*, comments on this deficiency thus:—"The omnibus (a small and unsuitable vehicle), and the river steamer (a boat of small power, but having a good awning), start at the same moment, in consequence of which the visitor often misses both. In despair he is driven to travel over two kilomètres (about 1¼ mile) of dusty road under a burning sun. He returns in the same way, and, out of breath, arrives at the station in time to see the smoke disappearing under the bridge." In fact, the much-vaunted system of Parisian omnibus correspondence is, in this case, one cause of vexatious delay and fatigue.

My own experience was somewhat similar; for, starting from the station of the Fernes, not far from the Arc de Triomphe, I arrived shortly at the Point du Jour station (ominous name "break of day"), and found no omnibus whatever going in the direction of Billancourt; so I sat in the shade, till refreshed with beer, I "took," as our neighbour's say, "courage in both hands," and under a tropical sun proceeded to the island on foot. The heat of that hour would have astonished any one. The road is extremely white and dusty, flat, and of the market-garden character, though laid out already in building lots. The soil is a chalky loam, but porous, and with access to water, would, by enriching, bear good garden crops, or Vines, many of which we see on the distant slopes. The whole is but little above the water level, but the splendid climate supplies many defects.

At last with weary feet I reached the bridge over the river leading to the island. The stream is of a green grey hue, but not turbid, and runs at about three miles an hour at this season. I could see that it had been 4 or 5 feet above the present level during the winter floods. The scenery is tame, and the absence of steamers and pleasure boats contributes much to its monotonous character. Tall masts, from which tricolor pennons were flying, gave a transitory though theatrical gaiety to the bridge. To an English eye this seems tawdry, but it is not so very easy to render buildings suitable for the exhibition of machinery or cattle interesting.

After paying one sous "*pour le pont, Monsieur*," I found myself between two ugly rows of Norwegian-looking sheds, seemingly destined for the sale of beer, wine, and spirits. These, also, had their appropriate flags, and appropriate inmates too. Certainly the increase of drunken men in the streets of Paris of late years is conspicuous, and Emile Girardin in his journal notices the crowds of workmen round the English restaurants, and ironically says they must be strangers whom the march of civilisation has converted into topers and Frenchmen, so like a native is their language.

The politeness of the Acting Superintendent spared me much time and fatigue under that fierce sun, without means of obtaining shade save among the drinking-sheds. Those to whose lot it fell to be present at the earlier stages of the Exhibition building know how much invaluable time they expended in finding out their special objects.

The visitor on entering will find on his left-hand a space devoted to horticultural objects, which are worthy of his notice. The section devoted to these is in the Park of the Exhibition near the Ecole Militaire, and contains the principal objects of this department. The visitor, however, whose chief desire is to inspect some of the machinery or cattle, may thus examine some fine specimens of trained trees shown by Baltet, of Troyes, who is considered here a clever cultivator. The trees shown by him are enclosed, and called the Emperor's Garden. Some fine diagonal Pear cordons by Professor Gressent are worth looking at, as he also has a high reputation. Specimens of neat little Apple cordons as edgings may be seen in front of them also; and a method of bending Pear shoots by Oudin, of Lisieux, is practical and ingenious. Shrubs were still being planted, and walks made on the island, which if made permanent will be a great improvement. A small collection of stocks was exhibited, among which were the following:—Quinces from Angers, Lisieux, Orleans, and Portugal; the Paradise, Myrobolan, St. Julien, the Mahaleb, and Prunus spinosa. There was also a collection of French Hops, as well as a very interesting show of Vines trained for vineyards, from which the English visitor may gather an idea for training Vines under ground vineries; some curved specimens are particularly recommended to his notice, as also the very old stumps still in good bearing condition.

showing some excellent vineyard forms. Some clean-looking high standards of Pears, Apples, &c., are conspicuous.

At this period the mid-day sun was most trying; the workmen in blue linen blouses had their pocket-handkerchiefs spread, Indian fashion, over their caps, and I was glad to throw myself under some Poplars near the stream. All round, the hills near Paris, thick with villas, Vines, and clumps of trees, were under a thick haze of heat, and a sky without a cloud.

But this was not the way to become acquainted with the other objects exhibited, and Billancourt is chiefly destined for a future dog and cattle show, besides the machinery and agricultural implements now there. So I returned towards these, and found a group of Englishmen watching the ascent of a clumsy French cultivator up a short path. The machine groaned and quivered as the steam was raised to a sufficient strength, but by obliquing, as an old horse will up a hill, the cultivator managed to do it, and then rumbled down the walk to a distant part of the island, where I speedily saw it at work on the soil. Further on I came on a white smockfrocked Englishman in an agonised struggle to equip an English horse in, to him, a bewildering maze of white French harness. Very international looked Diomede's head in his Gallican gear, with flowing tassels, and the good brute seemed somewhat downcast withal. "Coom oup" in the broadest Somersetshire, then some fearful insular denunciation unfit for these pages. "It wunna draw;" then a pull at the bellyband; but, after all, it did not appear a success. I thought the Norwegian sheds would soon have a thirsty occupant, but ventured mildly to ask what Somerset thought of the French cultivator, not deeming my own opinion final. After another fierce struggle with the white harness, I was informed that four horses would do better. This is conclusive to my mind.

Then the sheds were examined, and some foreigners criticising our hay-making machines, asked for the "address of my house," as I was reposing on some less formidable engines.

Ruston, Proctor, & Co.; Clayton; Robey; Ransomes & Sims; Howard; Smyth & Sons; Picksley & Sims; and Garrett, are here well represented in many branches.

Canada shows ploughs; the United States their excellent reaping machines. The Belgian department is very fine, ranking next to the British, with portable engines. The French threshing machines are more simple than ours, and thus more suitable for small farms. The engines driving them are of less force, lighter, and better suited for transit over bad roads. In drills the French makers often approach suspiciously near to our own; but in spite of this, in workmanship and design, they cannot be compared with our best manufacturers.

There were a few waggonettes shown, one was priced at £45, and was dear at that sum. Some wheels of fine execution were also dear. They were numbered according to force, from 1 to 10, one about 30 inches in height being estimated at "force 2," and priced forty-one francs.

Further on the visitor finds at present a cattle show, which will be greatly developed hereafter. The sheds are airy, and a single line of rails embedded in the asphalte runs down the middle. Dutch, Norman, and very small Breton cows are here, and are very good. The last were reported to me as producing some fabulous amount of butter, which our Channel Island experience did not at all confirm. The cattle were in high condition, exhibiting fine broad backs, and there were some pretty cream-coloured specimens of natives crossed with our short-horned breed.

No doubt in the summer show something will be visible here. At present much is in an incomplete state. There are no authenticated names as yet over the stalls, and little reliance is to be placed on the accounts of the attendants. I saw no English cattle here, nor any from the Channel Islands: such are coming later. There are also no English trees here of any description.

By this time I had reached the melting point, and took refuge in the steamer with many others. None but business people were there, and no ladies of course. A delay of about three-quarters of an hour took place, and at 3 P.M. (the visitor should note this, and select this mode of return conveyance), we began to ascend the stream at about a walking pace. The current will try some of our boating men's prowess, but the river will be much lower by July. The Seine is uninteresting enough, but there is a very comfortable awning over the deck of the steamer. The return journey was thus far more agreeable, and, no doubt, ladies will choose this way, as we landed close to the Exhibition building.—T. C. Bréhaut.

THE GARSTON VINEYARD.

(*Concluded from page* 262.)

On resuming our walk through the house of mixed Vines, one is struck with the superiority of the Black Alicante over all other Grapes. There is scarcely a house in the Garston Vineyard which does not contain several Vines of this most valuable Grape. See it where you will, no matter in what aspect, it has the same beautifully finished appearance. The great advantage which it has over Lady Downe's is its free setting. Lady Downe's is equally valuable as a late-keeping Grape, but very often it is a shy setter, and the bunches are in consequence very ragged; the best plan to adopt is, when it is in flower, to give a gentle skiff with the syringe. In 1864 I exhibited at the Crystal Palace September Show a basketful of Lady Downe's Grapes, weighing 36 lbs.; they were as fine as any I have ever seen of this variety, both in point of colour and evenness of berry; the flavour was also all that could be desired. The house in which they were grown was started on the 1st of December, 1863; they were ripe in the second week in June; and from that time up to the first week in September scarcely a berry shrivelled, and the colour remained as perfect as possible on several bunches which were left on the Vines till the end of October, or eleven months after they were started. I just mention this to show that to have Lady Downe's in perfection it is necessary to let it hang a long time after it is ripe; and to ensure its keeping well throughout the winter it should be ripe by the second week in October. If it is well ripened by that time, and the roots are in a good state, the bunches will hang perfectly fresh and plump till the end of February or middle of March. The same may be said in favour of Black Alicante.

The next Vine that met my view was a Barbarossa; this had three bunches on it. One of them measured 23 inches long and 16 inches across the shoulders, and its weight could not be less than 13 lbs.; it was not, perhaps, quite so well coloured as some of the others, but it was a splendidly-formed bunch, and would doubtless have been well finished in point of colour had the autumn been more favourable.

The next Vine was a Black Alicante; this had five large bunches, which would average 4½ lbs. each. In one of the bunches I noticed a berry of extraordinary proportions, as large as the largest Kirke's Plum, and, like the rest of the berries, as black as Sloes. I thought it might be worth while to save the seeds, to see whether the Vines raised from them would produce berries generally of like proportions. The berry was not like those which are often met with—double, but perfect in itself. I have since forgot to ask Mr. Meredith if he saved the seed, and if so, what number of seeds the berry contained.

On one Muscat of Alexandria Vine in this house I noticed eight beautiful bunches of fruit; they would average not less than 3 lbs. each, and exhibited that beautiful amber shade indicative of the highest state of perfection in this variety. The berries were large and very even. The neighbouring Vine to this was a Black Alicante, which had five splendid bunches averaging 4½ lbs. One of these, at the top of the Vine, I should think would not weigh less than 7 lbs.; it was a perfect model, the berries being beautifully coloured, and as even as if cast in a mould. Next to this I saw a White Tokay with seven bunches, averaging about 3½ lbs.; these were also beautifully finished. The next Vine I passed was Child of Hale with three bunches, which together would weigh not less than 32 lbs. This Vine produces some immense bunches, but there appears to be some difficulty in ripening them properly. Like the Lady Downe's Grape, I think the variety must be started earlier in the season to have it in perfection.

Altogether there are fifty-seven Vines in this house. September is the best month to see it in perfection. Mr. Meredith told me on leaving it that he had never before experienced so much difficulty in colouring Grapes as he had done that autumn.

We next entered what is called the north house; and many good Grape-growers, had they seen this splendid houseful of Grapes, would have scarcely believed such wonderful results possible in a building of such simple construction, and situated in an aspect one would think so unsuited to the growth and well-being of the Vine; but here were Grapes, principally Black Alicante, Lady Downe's, and Barbarossa, as fine in bunch, having the same evenness of berry, and in colour quite as good as any in the house I had just left, and of which the aspect is due south. The house is 128 feet long by 17 feet wide, and the roof, which is very flat, is glazed with Hartley's

rough plate glass. There is a row of large trees which overshadow this house very much, so that the light is very much obscured. The house is situated close to a brook which runs past the Vineyard. The greatest evil which Mr. Meredith has to contend with is the dampness caused by the proximity of the house to the brook; but after seeing such a houseful of Grapes as this, surrounded by so many disadvantages, no one need hesitate a moment to build a vinery in any aspect. I would defy any one to pick out a situation to all appearance more unsuitable than that which this vinery occupies; not a gleam of sunshine can by any chance fall on it. There were several Trebbiano Vines, each bearing three fine bunches, in point of colour, form, and evenness of berry, nearly as good as the splendid bunches exhibited by Mr. Drewett, at the St. James's Hall Show, some years ago. The Alicante and Lady Downe's were also remarkably well coloured.

This house was originally used as a potting-shed, then pot Vines were placed in it, and about four years ago Mr. Meredith introduced three rows of four-inch pipes, and made a border about 5 feet wide and 4½ deep, and this is all these Vines have to grow in at present; but he contemplates adding another 5 feet of border on the inside, and a border on the outside as well. This house, though evidently not built with the idea of growing show Grapes in it, yet contained at the time of my visit many splendid bunches that would have graced any exhibition. There were several bunches of Barbarossa, weighing from 6 to 12 lbs.; these were black, and the berries large and even. Child of Hale was also well represented in this house; one bunch measured 15 inches in length and 13 across the shoulders. Bunches of Black Alicante, weighing from 2½ to 4 lbs. might also be counted by dozens. There is a light about 18 inches deep along the front of the house. This is opened by means of a spindle and lever; the top lights are opened in a similar manner. I must say I was very reluctant to leave this house; but time was pressing, and I had several others to look through, and two of these are undoubtedly the finest vineries in Europe. These I shall proceed with after passing through two small houses. One of these, a Black Hamburgh house, is very much elevated above the general ground level. Here the borders cannot be much less than 6 feet deep—inside. This was the first vinery Mr. Meredith ever possessed. It was built on a small place which he at first occupied near his present establishment. The Vines had been planted, previous to their removal with the house, about two years; they were carefully taken from their original position and planted where they now remain, and from them Mr. Meredith has cut some of his best Black Hamburghs for the early London exhibitions. The deep-border system, with judicious care and proper management, appears to suit the Vines well. Their present appearance would warrant one in taking a fifty-years lease of their lives, if they were afterwards managed with a similar amount of skill. At the time of my visit (early in October), all the foliage had fallen, and Mr. Meredith was going to prune the Vines soon after I was there. I hear they have started better than ever this spring, and that they give promise of greater results this season than they have afforded in previous years. This house is so situated that extensive outside borders cannot be added to it: hence the necessity of making the border of extra depth.

Adjoining the Black Hamburgh house Mr. Meredith has built what I consider is the best and most useful house I ever saw for growing a few early Vines. He told me he had built it with the odds and ends left after the completion of the large range which he built last spring. The house is span-roofed and very substantial. There is a lantern above the ridge of the roof, and the sides are opened by leverage from the centre path; there are also side lights 2 feet wide, which all open very easily. No outside border can be formed to this house, but ample provision is made for a good deep border inside. The four walls are built about 6 feet 6 inches above the general ground level. The whole of the space inside will be occupied with the border up to the wall-plate level.

After leaving this structure we cross the yard, passing the bothies, stabling, workshops, &c., on our way towards the eastern extremity of Mr. Meredith's establishment. This brings us into a portion of the ground which is at present devoted principally to fruit trees. On a part of it stand two of the finest vineries ever built. A vast amount of interest will be attached to these houses during the next ten years, for in them Mr. Meredith has planted every known kind of Grape that is worth growing. He has also numerous experiments in progress. Various kinds of Grapes are grafted and inarched on every conceivable variety of stock, and it may therefore be concluded that his experiments when completed will be of great benefit to Vine-cultivators generally. I believe Mr. Meredith is only waiting to see the result of these experiments to complete his elaborate treatise on the Vine. This I am sure will be read with great interest by the gardening public, who will expect to find in it a vast amount of information which no one is better able to give. The two houses above referred to are span-roofed, and each 144 long by 26 feet wide. One of them is devoted to the growth of white Grapes, the other is for cultivating all the best black varieties. There is a path 6 feet wide through the centre of each house, and provision is made for heating the borders if it be found necessary to do so. The ends of the houses are due east and west, so that one-half of the span faces the south and the other is due north. The Vines are planted on each side of the house, and the border for each set of Vines is 10 feet wide, and about 5 feet deep. Both houses are built in the same manner, and with materials of the very best description; some idea of their stability may be formed when I state that they cost little short of £3000. The quantity of material used in their construction must have been enormous. They are fitted together in the strongest possible manner, yet there is nothing heavy-looking about them. The side walls or pillars are built about 5 feet 6 inches above the ground level; on these are placed solid blocks of stone, on which rests the wall-plate. The spaces between the pillars are filled up with loose bricks, which can be easily taken out so as to give the roots free access to the outside borders when the time shall have arrived for making these. The pillars are about 14 inches by 9, and the spaces between the pillars are about 20 inches wide. The side lights are 2 feet 6 inches high, and are easily opened and shut by means of a lever and spindle at intervals of about 50 feet. There is a similar contrivance for opening the ventilator in the roof. The perpendicular height from the level of the central path to the ridge is about 13 feet. There are six large tanks in each house for holding a supply of rain water; they are 10 feet long, 5 feet wide, and about 7 feet deep, and the whole of the water that falls on the roof of each house is conveyed into these cisterns by means of iron pipes. The borders in both houses have been made with great care, and the Vines are planted 2 feet apart. There are in each house 144 Vines, which have been planted three years; many of them were at the time of my visit carrying from 8 to 12 lbs. of Grapes, and most of them were bearing three or four bunches each. Had they been my Vines I should have waited till this season before I allowed them to bear such a crop, and Mr. Meredith himself thought he had been too hard on them; but to look at them one would think they were capable of bearing a much heavier crop. I think, however, that every care ought to be taken not to weaken the constitution of the Vine until it has stored up sufficient food to enable it to bear without injury a heavy crop of fruit.

In the house devoted to the cultivation of white Grapes, I noticed splendid examples of Foster's White Seedling, Child of Hale, Muscat of Alexandria, and White Tokay. The latter Mr. Meredith considers one of the most valuable white Grapes for late work. Many of these kinds were grafted on Black Hamburgh, others on Barbarossa; some on Lady Downe's, Black Alicante, and others, whilst many were on their own roots; so that Mr. Meredith will have every chance of proving each variety, both on its own roots and on stocks of various kinds. In this house I tasted a splendid seedling white Grape, which was certainly of first-rate quality; the bunch was large, and the berries very similar in appearance to those of the Muscat of Alexandria, whilst the flavour was rather more agreeable than in that variety generally. The berries appear to set very freely. We shall hear more of this fine Grape in due time. Mr. Meredith thinks it will prove a most welcome variety for early forcing. If, as I believe, it prove to have all the good qualities of the Muscat of Alexandria in point of appearance and flavour, with the free-setting qualities of the Black Hamburgh, it will be a most welcome addition to our early Grapes. I know that one is sometimes liable to be led astray by appearances, and the palate is not always alike; but I certainly thought at the time I never tasted such a luscious Grape.

I think I have enumerated all in this house likely to be of interest at the present moment. On each side of the path stood a row of splendid pot Vines, with canes from 10 to 15 feet long.

On entering the house in which all the best kinds of Black Grapes are planted, splendid examples of Black Alicante were

to be seen; also fine bunches of that handsome-looking Grape Gromier du Cantal, with its large amber-coloured berries, mottled with light purplish brown. How unfortunate it is that this handsome Grape has so little flavour to recommend it, its only good quality consisting in its beautiful appearance. Lady Downe's and Black Alicante were most conspicuous for the depth and richness of their colours. Judging from their appearance, there were many bunches of Alicante in this house that would weigh 5 or 6 lbs. each, and not a badly-formed or imperfectly-coloured berry could be seen. There were also some very fine bunches of Barbarossa in this house, and Jura Black Muscat looked very promising; the bunches of the latter were jet black. Mr. Meredith told me that it keeps well, and is likely to prove a valuable late Grape. Ingram's Hardy Prolific Muscat was also in very fine condition; this is certainly a most valuable Grape. Snow's Muscat Hamburgh [Black Muscat of Alexandria], grafted on Lady Downe's, was remarkably fine. I noticed another seedling, a black Grape; the berries were very large, but as it was not nearly ripe I had no chance of tasting it.

As I was leaving this splendid house Black Alicante again attracted my attention. Mr. Meredith here told me he had kept it perfectly fresh and plump for nearly ten months. I consider Mr. Meredith ought to have a medal of honour awarded him for re-introducing this valuable Grape into notice. He has been again successful in gaining the medal of honour at the Brussels Horticultural Exhibition, and it is gratifying to see the collection of medals he has had awarded him by the Continental as well as English horticultural societies.

There are at present six rows of four-inch piping in each of the houses just referred to, but it is intended to add more when the Vines are properly established. Extraordinary provision is made for outside borders to each house; Mr. Meredith particularly insists on this point. The two houses are built parallel with each other, and there is sufficient space between them for a 10-feet walk, and an 18 or 20-feet border for each house. The site intended for the outside borders is at present occupied by Strawberries.

I must here correct a statement which I made in the second column of page 261, that "each set of branches would have just 51 feet to travel from the main stem;" this only applies to one division of the house. The house is 202 feet long. Mr. Meredith might plant Muscat Grapes in one division, and Hamburghs or another black kind in the other.—J. Wills.

ROSE PROSPECTS.

A hasty look-in upon my good friend at Okeford Fitzpaine last month suggested naturally something about Roses; and as I have had various communications from different friends on the subject of their losses, a few words may not be uninteresting to the very numerous body of amateurs who delight in the queen of flowers. Mr. Radclyffe is beginning to feel at home, and is extending his operations. More walls are being built, and, if I mistake not, we shall learn something from him yet about fruit-growing. A large portion of his newly built wall fell during the winter, and this has very considerably interfered with his plans. As it was, however, I saw fine bloom on some maiden Peach trees on the cordon system, and should be glad if he be able to secure fruit from them, as I am not aware of such a feat having been yet achieved. His Strawberries were perfect, and if this lovely weather (May 3rd), continue, I think both he and all Strawberry-growers will have a successful season.

The effects of the frost, or rather the area affected by the frost of last January, seems to have been very various, and to have been in many instances quite different from that of some former ones. The valley of the Thames seems especially to have suffered; while the midland counties, as far as I can learn, have not met their usual fate, frost being generally more severe there than on the coast line. Hertfordshire also seems to have escaped pretty well; but I must give it as my humble opinion that we do not yet know the extent of our losses, as wood looks green, throws out a few shoots, and then begins to die away. This is more especially the case when, in cutting the shoot, the centre or pithy part looks brown—an indication, I fancy, that the frost has caught the Rose there. The losses, too, are very great already. Thus, I knew of one grower who has lost two thousand plants of Maréchal Niel, suggesting, I very much fear, that my early doubt as to its hardiness is too likely to be realised. Then, I know another grower who has lost every dormant bud in his grounds; and another who, on a piece of five acres of rather elevated ground, has very few left.

Mr. Radclyffe's Roses were, as might well be supposed for so experienced a grower, well protected. His plan is to spread litter or straw over the roots (the plants being all on Manetti), and then to earth them up as one would earth up Potatoes. This must necessarily save the roots from frost, and also from what he and I both find to be a great enemy—wind. Yet with all this everything had been cut down to the snow line; and although his positive losses—the dead of his army, were few in proportion to his stock, yet I am sorry to say his "nominal list of wounded" went up to a very high figure. His fine yellows were dreadfully cut up, and in some instances right back to the very "bole" where there were some few signs of life, while a large quantity of wood had to be cut out from many of his finest plants. I do not think that much reliance is to be placed on lists such as those furnished by a correspondent in a contemporary as to the kinds of Roses that are hardy. What he has found might be very right for his own district, or his own garden rather; but I should advise every one to go by his own experience, see what is the character of his soil and the condition of his plants, and then, as he finds they have withstood or survived the winter, so let him be guided for the future. I say condition of his plants; for if one had been removed in the autumn and another not, the probability is that the former would have been comparatively uninjured, the latter much cut up. Much has been said about Roses on their own roots, and the manner in which they have withstood the frost: it may be so, but I have not found them do it better than those budded low on the Manetti.

On the whole, then, looking at the present state of things, I somewhat tremble for our Rose prospects. I cannot feel that we have a probability of seeing such grand shows as we have had, and that many a rosery has been spoiled of its beauty. This is one of the "chances of war," and rarely does a season pass over that is not trying to some class of plants. The past winter has been trying to a good many, but the lover of flowers is not daunted; he sets to work again with fresh vigour, and hopes from the experience of the past to gain lessons for the future.—D., *Deal*.

THE EFFECTS OF THE SEVERE WINTER AT MESSRS. IVERY AND SON'S,

DORKING.

It was not till within the last three or four weeks that the effects of the late severe winter, succeeded by the cold weather of March, were made fully evident. It is now certain that the injury sustained by exotic plants generally considered hardy, is much greater than was at first anticipated, and that the losses by death exceed those in any previous season within recollection, not excepting the memorable winter of 1860-61. Providentially the intensity of the cold was unequally distributed, arising chiefly from the local circumstances of situation and soil in connection with surrounding influences. Had this not been the case—if the temperature had been uniformly so low as registered in several places, many of our most valued ornamental trees and shrubs would have been exterminated.

From the evidence already given in these pages it has been seen that the readings of the thermometer varied very considerably in different places. The variations were similarly remarkable in this neighbourhood; in my garden (Blechingley, Surrey), one of Negretti & Zambra's instruments placed against the east side of the dwelling-house, but not near any chimney or anything likely to influence it from within, on the night of January 4th-5th registered 19° of frost. In another garden, about half a mile distant, in the vicinity of water, and lying somewhat low, 25° of frost were indicated; in a third, two miles distant, with a heavier and more clayey soil, 31°; while in the valley of the Mole, at Dorking, ten miles distant, and in its immediate neighbourhood, the temperature sank so low as to range from 6° to 12° below zero—that is to say, from 38° to 44° of frost.

The effects, therefore, of the cold upon plants exposed to it in each of the places referred to, as regards death and injury, have been in proportion to its intensity or nearly so, and hence at Dorking most severe. It is with feelings of sincere regret that I have to report one of the most disastrous visitations probably known. As above stated, the temperature in the valley of the Mole sank so low as from 6° to 12° below zero on

the night of January 4th-5th, and the cold of the succeeding fortnight was doubtless similarly proportioned to that experienced at other places. In this valley is situated the well-known nursery of Messrs. Ivery & Son, and upon this devoted spot and the neighbouring gardens has the severity of the weather told to a fearful degree, causing death and injury to trees and plants to an unprecedented extent.

Wherever there is a first-class nursery established, the horticulture of the neighbourhood is sure to be beneficially influenced, the standard of gardening is raised, and the taste for beautiful plants spread and improved. This is very applicable to these nurseries, and your respected correspondent "D., *Deal*," in his article upon Denbies at page 143, has very aptly remarked that "Dorking is a classic name to the English horticulturist;" for, although, the high repute of the firm in the horticultural world is in a great measure due to the untiring energy and perseverance with which the successful cultivation, and the raising and collecting of new varieties of hardy British Ferns and of Azalea Indica, are pursued, other departments have also received especial care, particularly the growth of ornamental trees and shrubs; and the pleasing appearance of the numerous gardens around Dorking and Reigate, where the fine scenery afforded by the Surrey Hills, and the undulation of the district, have attracted so many different residents, is in no slight degree owing to the fine specimens with which they have been enriched from Messrs. Ivery's nurseries. Specimen plants of all the principal Conifers and evergreens are kept in considerable numbers in the home nursery for the selection of purchasers, and it is upon these that the severity of the late winter has fallen with unsparing rigour.

Having for many years made frequent visits to the nursery, the feeling of depression which attended an inspection of it a few days ago may be easily imagined. Some idea may be formed of the destruction, when I state that plants of Araucaria imbricata from 6 to 12 feet high are killed, not here and there a single specimen, but by the score—indeed in an avenue of finely grown trees, scarcely one is left that will be of service—Deodars from 10 to 15 feet high have been killed to the snow line, and in some cases are quite dead. A Cedar of Lebanon 15 feet high is dead or nearly so; Cedrus deodara robusta, a fine specimen, 10 feet high, is also dead; Abies Morinda 8 or 9 feet high, and Pinus excelsa of the same height are also dead; and, which is much to be regretted, a fine old plant of Berberis Darwinii which when in bloom has always been a conspicuous object, is killed to the snow line. In fact, except those to be presently noticed scarcely a quarter assigned to any particular kind has escaped uninjured more or less, and in some instances the whole stock is entirely destroyed. The utility of snow as a protection was here very distinctly and even remarkably proved. The snow was about 16 inches in depth, and in those quarters occupied by young plants which were entirely covered by it, the greater part have escaped, and, wherever the tops of plants were exposed above the snow, that portion was killed. In the case of large plants the bottoms that were under the snow are still alive and breaking into foliage, although all above is destroyed. Throughout the grounds the place of the snow line can be clearly traced. So assured was Mr. Ivery of the protection the snow was affording, that he had a stock of evergreen Magnolias, M. grandiflora, M. exoniensis, &c., only slightly protected, banked up with snow both above and around, and every plant was saved.

I subjoin a list from my notes taken on the spot which I have arranged under the different headings of killed, injured more or less, and uninjured.

1. Killed.

Cedrus deodara.—Nearly every plant killed, or so severely injured as to be worthless.

Cedrus libani.—The same as the preceding.

Cedrus deodara robusta.—Large plants killed; smaller ones killed to the snow line.

Cupressus Lambertiana.—The whole stock.

Arthrotaxis Doniana.—A plant 3 feet high, slightly sheltered.

Cupressus sempervirens.—The same; a few escaped, but were very severely injured.

Araucaria imbricata.—As above stated, probably four-fifths of the whole number; the rest rendered useless.

Abies Morinda.—Some large specimens, while others were apparently uninjured. A singular instance of the capricious effects of the cold.

Pinus excelsa.—Nearly all the larger specimens; others much injured.

Pinus insignis.—The whole stock.

Portugal Laurels.—The same, or nearly.

Common Laurels.—The same, or nearly.

Arbutus unedo.—All the larger plants.

Rhododendron ponticum.—A whole bed.

Quercus ilex (Evergreen Oak).—The whole stock.

Laurustinus.—The same.

Roses.—Seventy-five per cent of the whole.

2. Injured.

Besides the above, this list includes many kinds where the death of individual plants or of more than one was not observable.

Abies Douglasii.—More or less.

Juniperus recurva.—Large specimens, 5 and 6 feet high.

Libocedrus chilensis.—Killed above the snow line.

Cupressus elegans.—The same.

Taxus (Yew), of varieties.—Slightly.

Arbutus.—All much injured, especially A. Milleri, A. photinifolia, A. magnifica, and others.

Aucubas.—The common variety, slightly.

Escallonia macrantha.—Killed to the snow line.

Ivies.—Upwards of thirty varieties very much injured, many of them killed to the snow line.

Hollies.—Most of the variegated, and many of the green kinds, some very severely.

Hybrid Rhododendrons.—Very severely.

Cytisus (Broom), the double-flowering Furze, and even Box and Pampas Grass, the last slightly protected.

Euonymus japonicus.—Severely.

Jasmines.—Some kinds.

The foregoing lists do not include every kind of plant or tree injured or killed. I have noted the most conspicuous instances among well-known species. For the same reason, in adding a list of kinds that have escaped uninjured, which is equally interesting, since we may know from it those capable of enduring the severest ordeal our climate can inflict, the high estimation in which many of them are justly held will certainly be enhanced.

3. Uninjured.

Abies Albertii, A. orientalis, A. Menziesii, A. Clanbrasiliana, and its varieties.

Cryptomeria japonica, C. japonica araucarioides, and C. japonica nana.

Cupressus Lawsoniana.

Sciadopitys (Umbrella Pine).—Very slightly sheltered.

Juniperus.—Of upwards of thirty kinds of Juniper, the only ones injured are some large plants of J. recurva previously referred to. All the others that came under my notice were in perfect health. This beautiful class of ornamental plants will, doubtless, gain increased favour, not simply from their hardy character, but also from their peculiar but pleasing habit, and colour of foliage.

Pinus.—Besides those naturally found in countries with severe climate, the following have escaped uninjured:—

P. Bentbamiana, P. laricio, P. Lambertiana, P. Beardsleyi, and P. Pallasiana.

Picea (Abies).—P. Nordmanniana, P. pinsapo, P. amabilis, P. nobilis, and P. cephalonica.

Retinospora obtusa, and R. pisifera. These recent introductions will, therefore, prove valuable acquisitions.

Thujas.—T. aurea, T. compacta, T. Lobbii (gigantea), and T. gigantea (Libocedrus decurrens), besides the well-known Chinese Arbor-Vitæ (Biota), and its varieties.

Thujopsis borealis, T. dolabrata, and T. Standishii.

Wellingtonia gigantea.

It is impossible to avoid expressing satisfaction that there are some of the most beautiful forms of the Coniferæ which we possess found also to be the most hardy. A winter garden out of doors may yet be a reality in England.

The deciduous shrubs and trees appear to have suffered least. Mr. Ivery hopes that the generality of them have escaped without material injury. The Purple Magnolias are showing bloom freely.

A word or two on the Roses. An inspection of the quarters showed plainly that not less than three out of every four are dead. The effects, too, have been strangely capricious, as it has always happened with Roses. As a rule, the whole of the Noisettes and Teas exposed are killed, as well as most of the Bourbons, and those that have generally been considered tender. Among the Remontant Hybrids (H.P.s), some kinds have passed through the ordeal entirely unscathed, while of others the whole stock is killed. Some, again, have been severely injured, while there are instances where one plant is safe and sound, and its next neighbour of the same variety is quite dead.

The following first-class Roses have escaped—Charles Lefebvre, Senateur Vaisse, Jules Margottin, Prince Camille de Rohan, Baron Gonella, and Général Jacqueminot. Of these favourites, I did not observe a plant affected. On the other

hand, the entire stock of Empéreur de Maroc, Anna de Diesbach, Mdlle. Bonnaire, Souvenir de la Malmaison, Celine Forestier, Auguste Mie, and Duchesse d'Orleans, are killed. John Hopper, Chabrillant, Count Cavour, and Beauty of Waltham, all first-rate, are severely injured, and even Gloire de Dijon has suffered much. Fearful as the havoc has been among them, I was glad to find that Mr. Ivery has a fine collection of plants in pots, chiefly on their own roots, in first-rate condition, and now pushing forward in one of the pits, but, of course, totally inadequate in number to supply the place of the hundreds cut off out of doors.

Grateful was the relief afforded by the display of floral beauty in the different glass structures, after looking upon the sad spectacle of destruction out of doors. The Azaleas, the stock very extensive both in number and variety, now beginning to show their gay and charming colours, are, as they ever have been, in the highest state of perfection. Among those in bloom were—Belle Gantoise, rose and white; Criterion, salmon pink, magnificent; Flower of the Day, a light variety, very pretty; Excelsior, rose; Forget-me-not, brilliant reddish purple, very fine; Leviathan; Queen of the Whites; Stella, very good; Tricolor, a spotted variety; but unrivalled in beauty and delicacy of tint is a new kind, which obtained high honours last year, and is very properly named Fascination. Many plants of this gem are now in bloom, and offer a sight so beautiful, that it lingers in memory as strongly as it fascinates the eye in beholding. The encomiums already bestowed upon this noble flower cannot be improved by any addition of mine; it is lovely, and will maintain a chief position among the varieties of Azalea indica for a long time.

Nor must I pass by unnoticed a very fine strain of herbaceous Calceolarias, not only excellent in colour and form, but almost inclining to the character of the shrubby kinds, dwarf and compact in habit.

To do justice to the collection of British Ferns would fill a month's issue of The Journal of Horticulture; they are now beginning to unfold their lovely fronds, endless in variety and form. So rapid is the advance constantly being made, that at present upwards of four hundred varieties have been named and classified. Nor is there, probably, any assignable limit to which their variation may ultimately reach. Later in the season will be more appropriate for a notice of this interesting class of plants.—Adolphus H. Kent.

CULTIVATION OF PEAS.

I have read with much interest the article by "C. P.," at page 258, on the cultivation of every one's favourite—the Pea. The mode of culture there described is somewhat similar to that which I have practised for many years, both where the ground is very shallow and dry, and where it is of a stiff clayey nature, neither of which conditions is favourable to the production of good crops of Peas.

Where the ground is shallow and dry I take out a trench as for Celery, and about 15 inches wide and 18 inches deep, removing a portion of the subsoil, if necessary, in order to attain the requisite depth, carry away the subsoil thrown out, if any, in a barrow, return with this full of rotten farmyard manure, and add to every two parts of the latter one of good loam or fresh soil. If such cannot be obtained, soil from a road side, which has been kept in a heap for from four to six months, will answer. Put into the trench a foot deep of this compost, and over it an inch of soil. Then stretch a line down the centre and drop three rows of Peas, which will yield quite as well as five, and very differently from those we very often see grown on the narrow-drill system. Cover the Peas with 2 inches of soil, and leave the rest of this at the sides of the trench; it will keep off the cold winds if the crop is an early one.

As soon as the Peas are sticked fork back the ground between the rows, leaving it highest in the middle, and put some soil against the plants as the work proceeds. They are thus placed in a trench, and can, therefore, be conveniently and effectually watered, whilst they will receive the full benefit of all the rain that may fall. For watering, a hose may be attached to a tap, so that the water will run along the trench; or, if there is a stream in the garden on a higher level, it may be conducted by a channel to the Peas, as I have often done. I do not mind disfiguring my garden with a little stream running beside or across, a walk, if by such means I can obtain a good dish of Peas and this cannot be produced without plenty of water. If the cultivator has neither of the conveniences which I have mentioned, but has a pump on a higher level than the garden, he can put down draining pipes a few inches deep, or cut an open channel for the water.

I grow my Scarlet Runners just in the same way as Peas. If dung is scarce, all the refuse from the garden, such as that of Broccoli, Cabbages, or Turnips, and weeds, may be put into the trenches.

I like to have my rows of Peas 5 feet apart, and if I have not much room, I plant a row of some dwarf quick-growing crop in the intervals, so as to have it off the ground before the Peas come in. I endeavour, if possible, to have Scarlet Runners in a single row, for thus I find they produce one-half more. I also like to have water running in the row two hours a-day. This system answers better than sowing in drills, and, after sticking, banking up like Potatoes, the effect of which is to throw off the water. If one has plenty of hot dung, and wants a crop early, by making the trench deeper and wider, and then filling it with dung, the plants will have a hotbed to grow in; also the crop will be earlier still if roots of the previous year are planted.

As regards wet, stiff, clayey soil, I likewise form trenches the same as for shallow ground, but 6 inches deeper, and put in this depth of rough rubbish at the bottom as drainage. The trench is then filled up to the general ground level with a lighter compost than that used in the previous case. I do not use any of the clay soil, but procure light instead; I like that in which Kidney Beans, Strawberries, &c., have been growing in the houses.

"C. P." and her James have good soil, therefore in their case all this trouble is unnecessary. I do not perceive the use of having the Peas high; from 4 to 5 feet will be quite enough. —John Taylor.

THE FORS AND AGAINSTS AN ORCHARD HOUSE.

"*Audi alteram partem*" will ever continue a sound maxim; everything, including an orchard-house, has its pros and cons, and in forming a correct judgment upon the merits of any question all depends upon striking a correct balance between what we call in algebra the pluses and minuses. I well remember that chapter in De Foe's "History of Robinson Crusoe," in which he represents his hero, when cast upon the desert island, as summing up in so many alternate paragraphs—1st, The desponding thoughts which agitated his mind; and 2ndly, Those more favourable features in his case, which served in some measure to counterbalance them. With your good leave, I propose to adopt the same impartial method on the subject of orchard-house culture; and as the poet, comparing life to a chess-board, describes the former as—

> "A chequer'd scene, on which the trembling light
> Falls in alternate gleams of *black* and *white*,"

I shall beg to introduce to your readers my friend Mr. Potts, who has lately built an orchard-house, as placing each dark reflection that arises in his mind in juxtaposition with its corresponding white.

Black.—I have built a large orchard-house; it has been a considerable expense, the extras, including a tank, pump, and shelf for Strawberry plants, have exceeded by almost one-third the original estimate. My wife taxes me with extravagance, and thinks that the money would have been better expended in adding to my stock of household furniture, or providing an adequate supply of table linen.

White.—Never mind its liberal dimensions; size, if a fault, is one on the right side; it argues in me surely a Sir-Joseph-Paxton largeness of mind. Besides, it has been all paid for, and so is fairly my own, which is more than can be said of every coat on every man's back. Extras are an inseparable accompaniment of every grand design. I do not much mind what my wife says, she really thinks that "e'en my failings lean to virtue's side," and I have as much reason for charging her with a lavish expenditure when she rides her hobbies, as she me, when riding mine.

Black.—I cannot say that my house quite answers my expectations. I perceive that several spurs have only blossom-buds at their extremities (barren spray, Mr. Bréhaut calls these); a pretty kettle of fish after all my painstaking! Other lanky shoots have indeed a leaf-bud at the end, but all the other buds, both leaf and blossom, have clean dropped out; effects of unskilful pruning, of course.

White.—My house makes a capital lounge, I enjoy my weed

in it immensely. How jolly it is to bask in the sunshine when the east wind whistles outside! I am rather glad I built it, after all. When that barren spray is clean cut out plenty of spurs will remain, and several of them, I am glad to see, are furnished with double shoots. Hurrah! one for wood, the other for fruit! Alternate pruning!

BLACK.—My trees were covered with blossoms, but not a quarter have set; they strew the ground, and make me think of a place said to be paved with good intentions. I believe those little busy bees have knocked half of them off. I wish they would improve each shining hour instead of injuring my property. I saw a great bumble fellow on a very promising blossom, making it quite top-heavy.

WHITE.—I suspect that if all the blossoms had set they would have been more than my trees could bear. A dozen Peaches on each tree would not be a bad crop at a period when my trees can hardly be said to have arrived at years of discretion, and more than a dozen blossoms have set. In any case, I need not take the trouble to thin them—an operation recommended in the books, but requiring great strength of mind. By-the-by, I remember to have heard that bees are invaluable, and they seem to have been sent for the special purpose of scattering the pollen, which it would be tedious to effect with a camel-hair brush. How wonderful is the economy of Nature!

BLACK.—Alas! some boys have been throwing stones over the wall, and have smashed several panes of glass. What wretches boys are! I should like to give them all a sound cuffing. At this rate a fine glazier's bill I shall have to pay!

WHITE.—Boys will be boys. I was a boy once myself, and a bit of a pickle. I am fond of pickles, and appreciate exuberant spirits. There is something very charming in that freedom from care, that recklessness of consequences, and that mischievous disposition which characterises boys. It was very natural now of those urchins, who have accidentally broken my glass, to have been testing their projective powers, and it is a comfort to reflect that the apertures they have made in my roof will materially increase the ventilation of my house—no mean factor, I am told, in the product of orchard-house success.

BLACK.—The leaves that have made their appearance look queer. What makes them seem as if they had been twisted in curl-papers? Why! I declare they are covered with aphides; whence did they all spring from, I wonder? It is of no use killing one when a thousand come to his funeral. No wonder flies were considered one of the plagues of Egypt. I will make instant arrangements for giving my house a thorough fumigation.

WHITE.—Others are quite as much bothered with insects as I am. Is there not comfort in the thought? I cannot help feeling glad that so many innocent creatures have been indebted to me for the jolly time they have had of it. Why, my house must have been to them a perfect Elysium. My man, who, bellows in hand, is busy in the work of fumigation, must have the lungs of a rhinoceros to stand that smoke; he seems to like it, for he has a pipe in his mouth as well. The smoke almost stifled me, and the one whiff I had of it sufficed to convince me of its necessarily fatal effects upon entomological existence.

BLACK.—Why, I declare some enemies have been and bitten in half several of the young fruit. My patience is sorely tried, and will soon be exhausted. I suspect the thieves are some of those saucy sparrows that I see flying out when I come in. I should like to put some salt on their tails, and teach them, as Cowper so poetically has it, "never to come there no more."

WHITE.—If those little birds have diminished from my prospects of a crop, at all events they have filled their own crops. I never would be a member of a sparrow club, for sparrows do more good in a garden than harm, and merry England would soon become like France if we were to wage an exterminating warfare with our little birds.

BLACK.—The bill has come in for the tobacco paper. Let me see, 6*s*. for one lot (not the right sort), 4*s*. for shag (too damp), 9*s*. for more tobacco paper, which had, as my man quaintly observed, a pretty strong *scent* to it—19*s*. altogether. Surely my better half will renew her charge of extravagance.

WHITE.—I have earned a little experience, which, though dearly bought, is invaluable. It is not good to be penny wise and pound foolish. I have derived intense satisfaction from witnessing the fatal effects of fumigation on insect life. It is true that tobacco paper has cost me some shillings, but money is a circulating medium, and, no doubt, this outlay has contributed towards the remuneration of a very respectable class of manufacturers, whose profits (and I wish the same could be said of certain proprietors of tall chimneys), mainly depend upon the consumption of smoke.

BLACK.—I know not how it is, but whenever I go into that orchard-house I am bitten, some mysterious insect ingeniously contrives to find its way inside my trowsers, and bites me on my legs. It must be a very poisonous kind, for the inflammation it causes is painful and lasting; scratching makes it worse. I hardly bargained for this, Mr. Rivers, when in deference to your judgment I invested in an orchard-house.

WHITE.—The insect, no doubt, derives satisfaction from biting me; it evidently thinks me a nice man. Live and let live is a humane and generous sentiment. A little sweet oil has a most soothing effect, and relief from pain is nearly akin to pleasure. I daresay Mr. Rivers himself gets bitten, and I almost hope that he does, only as an advocate for orchard-houses he is wise to say nothing about it; it is for him to stick to the pros, and leave it to others to speak of the cons.

On the whole I consider—1st, That my contribution to your Journal will be considered too lengthy for publication; and 2ndly, That White has the best of it. I will only add my recommendation that the orchard-house cultivator should have a few Vines to train up his rafters, in case his trees in pots should turn out a failure.—A CONSTANT READER.

GARDENERS' EXAMINATIONS FOR HONOURS.

THE Royal Horticultural Society's examinations of gardeners for the present year are fixed to take place on the 3rd and 4th of July, and on the 30th and 31st of December.

The following are the conditions under which candidates will be required to compete, and the advantages which may be secured in the event of success.

"1. Diplomas will be granted to those who, having been certificated by the Society of Arts, or other public body of Examiners recognised by the Council, in Mensuration, in Book-keeping, in Practical Geometry, in Botanical knowledge, in Floriculture, and in Fruit and Vegetable Culture, shall also receive Certificates from the Royal Horticultural Society for practical skill in the cultivation of fruit and vegetables, and in the culture of flowers, and shall show a fair amount of skill in Surveying and Plan-drawing, and taste in Laying-out gardens. Such diplomas will confer the title of Associates of the Society.

"2. First and Second-class Certificates for the following branches of practical Gardening will be granted by the Royal Horticultural Society to candidates who shall pass the Society's examinations in those branches:—(*a*) In the operations of the Fruit and Vegetable Garden; (*b*) In the operations of the Flower Garden.

"3. A Medal will be presented annually to the candidate who, having taken the Certificates of the Society of Arts in Botany, and in the cultivation of Fruit and Vegetables and in Floriculture, shall gain the highest number of marks in Practical Gardening at the examinations of the Royal Horticultural Society.

"Candidates will be eligible for examination in Practical Gardening, if they have previously obtained Certificates from the Society of Arts in Botany and in Floriculture, or in Botany and Fruit and Vegetable Culture. A candidate who can present a written recommendation from any Fellow of the Royal Horticultural Society, from the President of any Floral or Horticultural Association acknowledged by the Society, or from the Director of any public park or garden, may also be examined in Practical Gardening."

The subjects of examination are very nearly the same as those laid down for the Society of Arts' examinations, given at page 66 of the present volume, and are as follow:—

FLORICULTURE.—The leading flowers of the different seasons, indicating those to be obtained naturally, and those by artificial means. Leaf-buds and flower-buds, the conditions favourable to their development respectively. Food of plants, how and whence derived, and in what form received. Manuring substances best adapted for flower culture. Improvement of races in plants, how has it been effected, and by what means can it be carried forward? Hybridisation, objects and guiding principles of. Conditions necessary to ensure fertility in flowers. Construction of houses for Plant Culture. Warming and Ventilation. Influence of ventilation on plants confined in forcing-houses. Limits of temperature endurable by plants, and how to turn this to advantage in practical Floriculture. Bottom heat, value of in plant culture. Watering, the *rationale* of—what to avoid. Liquid Manures. Propagation, the various modes of, and their special adaptations. Germination of seeds, conditions favourable and unfavourable to. Vitality of seeds, duration of, and how best preserved. Treatment of seedling plants. Budding, grafting, and inarching, how performed, and to what subjects best adapted. Increase by cuttings and by layers. Leaf-cuttings, how is it that they can organise buds? Potting. Composts. Acclimatisation: Is it possible to increase the hardiness of any race of plants, and by what means?

Text books: Lindley's "Theory and Practice of Horticulture,"

McIntosh's "Book of the Garden," Thompson's "Gardener's Assistant."

Fruit and Vegetable Culture.—*Fruits:* Kinds of Fruits adapted for various soils and exposures. The propagation, pruning, and training of fruit trees. The forcing of Fruit trees, and their cultivation under glass, both in and out of pots. The theory of ripening, and the principles that ought to regulate the preservation of Fruits after they are ripe, or their subsequent maturation. The packing of Fruit for transmission to great distances. *Vegetables:* The kinds and quantities of Vegetable seeds and roots required for cropping gardens of given dimensions. The culture of the different kinds of Vegetables and Salads. The preparation of fermenting materials for artificial heating. The forcing of Vegetables and Salads. *General Subjects:* Soils, water, atmospheric air, light and heat in their relation to the successful cultivation of Fruit and Vegetables. Manures and their application. The diseases and insects to which Fruit trees and Vegetables are subject, and their remedies. The structure and functions of the organs of plants considered in their relation to growth and reproduction. The erection, heating, and ventilation of garden structures.

Text books: Loudon's "Suburban Horticulturist," "The Cottage Gardener's Dictionary," Hogg's "Fruit Manual."

ROYAL HORTICULTURAL SOCIETY.

Weekly Show, *May 11th.*—On this occasion prizes were offered for six Pelargoniums, twelve Roses in pots, twelve plants (miscellaneous), and for collections of vegetables. Messrs. Lucking Brothers, nurserymen, Bayswater, were awarded a second prize for Pelargoniums. A first prize was obtained by Mr. W. Lynn, gardener to Lord Boston, Hedsor Park, Maidenhead, for a collection of vegetables, and an extra prize was awarded to Mr. H. W. Cordle, gardener to Earl Fitzwilliam, Coollattin Park, Gorey, Ireland, for three sorts of Potatoes. Extra prizes were also given to Mr. James Tegg, gardener to the Duke of Newcastle, Clumber, Worksop, for two dishes of Peaches, and to Mr. C. Osman, gardener to R. Holland, Esq., Stanmore Hall, Middlesex, for two boxes of cut Roses, also for a dish of Strawberries. Mr. W. Bartlett, Shaftesbury Road, Hammersmith, obtained three extra prizes for a collection of Ferns, a basket of cut flowers, and a collection of Spiræa japonica. A very interesting collection of plants, made up of Roses in pots, Azaleas, Gloxinias, Mignonette, &c., from the Society's gardens at Chiswick, formed a very pretty show.

NOTES AND GLEANINGS.

The ceremony of laying the first stone of the Hall of Arts and Sciences by Her Majesty having been fixed to take place on Monday next, May 20th, the Royal Horticultural Society has determined, upon the suggestion of His Royal Highness the Prince of Wales, to hold a Special Floral Fête on that day. The exhibitors of Tricolor Pelargoniums and other plants have been invited to contribute their specimens, and we are informed that special medals and prizes will be awarded, but that this Fête will not cause any alteration in the arrangements already published for the Exhibition of Tricolor Pelargoniums on the day following. The contributions to both, we are assured, will be most liberal and of the greatest horticultural interest. After the ceremony of laying the foundation stone, H.R.H. the Prince of Wales, and the Provisional Committee of the Hall of Arts and Sciences, will conduct the Queen through the south-east exit from the tent to the east door of the conservatory of the Royal Horticultural Society, where her Majesty will be received by the Council of the Society, and be conducted by the north-western terrace of the gardens to her carriage at the Prince's Entrance, Albert-road.

—— At the meeting of the Royal Horticultural Society held April 2nd, Mr. Bateman offered a plant of Dendrobium Wardianum as a prize for the best list of Orchids arranged according to the climate which they require. Five competitors, we are informed, have come forward, and the name of the successful one is to be announced at the general meeting on the 21st instant.

—— We are much gratified to observe that the eminent services which the Rev. Miles J. Berkeley has rendered to Horticulture and Agriculture by his profound researches and writings on Cryptogamic Botany, have been recognised by a grant of £100 per annum on the Civil List.

—— We regret to announce the death, on the 3rd inst., of Mr. John Dobson, sen., of the Woodlands Nursery, Isleworth, and who, before entering into business for himself, was for several years gardener to the late E. Beck, Esq. Both then and subsequently he was a frequent and most successful exhibitor of florists' flowers, and particularly of Pelargoniums and Cinerarias, as well as a raiser of some fine varieties. He had long suffered from, we believe, heart disease.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Manure and dig the ground as it becomes vacant for the winter crops of Brussels Sprouts, Broccoli, Greens, &c.; thin all advancing crops early. *Artichokes* (*Globe*), plant, using the strongest suckers; also *Basil* in rich warm soil, and *Capsicums* on warm borders. A good sprinkling of the Cape *Broccoli* may now be sown, likewise Grange's Impregnated Cauliflower, and Walcheren Broccoli; these will succeed the Cauliflowers sown in February. *Gherkins*, sow a row if not done. Those raised in heat in boxes should be hardened-off forthwith, preparatory to planting out. If a slight amount of fermenting material could be provided for them, after the manner of those on the ridge, by means of cut grass or other refuse fermenting matter, it would tend to insure a crop, and such is not so easily obtained in the northern parts of the kingdom as about the metropolis. *Celery*, plant-out the early plants in the trenches; also *Tomatoes* against walls and warm fences. With regard to *Peas*, *Beans*, *Spinach*, *Radishes*, *Cresses*, *Lettuces*, Horn *Carrots*, &c., we may repeat the advice offered in one of our earliest Calendars—viz., to sow a little more, if possible, when the preceding sowing is fairly above ground. Destroy snails and slugs by all available devices.

FRUIT GARDEN.

The spring disbudding of fruit trees is a matter of considerable importance at this period, for on thinning in due time and in a proper way, success in ripening both of wood and fruit is mainly dependant. The trees should be looked over when the young shoots are about 2 inches long, then in about a week afterwards, and finally in about another fortnight. The first dressing should consist chiefly in rubbing off foreright and ill-placed shoots; at the second thinning a selection of wood as to the necessary quantity and position may be made; and at the last all gross shoots or robbers should be stopped, in order to equalise the sap. Hand-pick the Currant and Gooseberry bushes if caterpillars appear, or dust with white hellebore powder. Thin-out weak shoots from Figs, and stop the others when 6 inches long. Thin the fruit of Peaches and Nectarines, and syringe often. Thin-out the shoots of Pears and Plums, and reduce the crop to the strength of the tree. Hoe and mulch Strawberries, and keep the runners cut off, except when wanted for forcing. Regulate Vines, and stop the laterals one leaf above the best bunch, removing any others. Look over the grafts, and relieve those which are growing by loosening the ties. Hoe among all bushes to keep down weeds, and loosen the soil.

FLOWER GARDEN.

It is now high time to think of bedding-out some of the mass flowers, at least such as are least liable to injury by frost, and have undergone a proper hardening process. Much may be done as to display by a judicious arrangement or combination of both colour and figure. As a general principle, our best authorities seem to agree that the various shades of orange and yellow will class well with the various purples and blues. Whites are suitable with the blues, oranges, and reds. White, however, deranges the effect of the yellows, as also the violet shades; whilst the various red or rose-coloured flowers are, as far as colour is concerned, capable of forming a bed by themselves. Auriculas must not be forgotten because the amateur has now many demands on his time; shade them in very hot sunny weather, though they cannot at this season be easily too much exposed, provided the regular attendance is given to watering, &c. Polyanthuses cannot bear the mid-day sun, except on very cool subsoils. A shady situation under a hedge with a north aspect will be suitable for them during the next three months—that is to say, if grown in pots. As regards Tulips, do not forget to fertilise some of the best breeders in order to obtain some good seed. It would be time and trouble thrown away to cross yellow grounds with white ones, or the contrary. In choosing sorts to produce seed, let them be thick in the petals, round at the top, pure in the cup, and clean in the stamens. Apply the farina with a small camel-hair brush to the stigma of the variety intended to be operated upon, and cover the flower with a hand-glass. Should the present dry weather continue, Carnations and Picotees will want occasional waterings, which, when afforded, should be plentiful. When a large stock of dwarf plants of Chrysanthemums is required for flower-garden purposes in the autumn, the old stools or plants must be planted in rich soil at about 4 feet apart, so as to leave room for their being layered in August. Old plants planted now at the foot of a wall in very rich soil will cover a wall

6 or 8 feet high by the autumn, and if properly trained will flower splendidly. We do not know anything more interesting in the dull months of November and December than a well-covered wall of these fine plants.

GREENHOUSE AND CONSERVATORY.

Camellias making their wood should have constant shading, the house should be kept very moist day and night, and the plants frequently syringed. Pay every attention at this period to plants of climbing habit, whether festooning the roof, trained up pillars, or on trellises in pots. Let stopping, thinning, and training proceed in a methodical way. Many conservatory plants are unproductive of blossom from the gross shoots not being stopped. To stop such frequently is to gain both time and space. Those who grow that delightfully sweet winter flower, the Cyclamen persicum, will find it the best plan to plant it out at this period in a highly-raised bed in the kitchen garden. This bed should be composed chiefly of peat soil and coarse sand, to which a little sandy loam and leaf soil may be added. It is truly astonishing what superior plants they make in this way. Be in no hurry to turn out of doors fine greenhouse plants, but all coarse and common subjects, and many softwooded plants, whose tops may be considered, in a manner, annual, may be turned out any time about the end of spring, and the finer portion of the plants will by this means have all the room, air, and light to themselves. Of all plants those in the greenhouse are most apt to become too dry in the summer, and, therefore, besides the regular watering, they may be well syringed every afternoon, in such fine weather as we have at present.

STOVE.

Centradenias, Eranthemums, Poinsettias, Justicias, Geissomerias, Clerodendrons, Euphorbias, Brugmansias, Gesneras, Vincas, and other ornamental stove plants, more especially those intended to flower in the dark winter months, should at this period have the highest cultivation. They should be allowed plenty of room, and clear manure water, and should, if requisite, have their rambling shoots stopped occasionally. The latter should be done forthwith, as young wood made late in the season will not produce winter flowers. Many stove plants would do better from this time until the end of August in an intermediate-house where they would have less confinement than in a regular stove. For want of such a house gardeners often make use of vineries for this purpose, and distribute their stove plants in summer throughout the different forcing-houses, and if only for the benefit of finishing and ripening their growth, without being crowded, this is a good plan.

PITS AND FRAMES.

Propagation must be continued until a full stock is obtained. Tender annual seeds for late flowering may still be sown. Very many plants that are difficult to strike from cuttings may be increased by grafting on the roots of some allied species. All tender seedlings should be potted as soon as they can be handled.—W. KEANE.

DOINGS OF THE LAST WEEK.

TOOK the opportunity of the bright dry weather before the thunderstorm of Friday to hoe all ground to which access could be obtained, in order to break up the surface, whether showing weeds or not. This was especially necessary where that troublesome weed, the large white Convolvulus, was throwing up its shoots like miniature Asparagus. Weeding is almost an impossibility in most kitchen gardens, and the most economical mode of keeping them clean is the use of the Dutch hoe frequently, and leaving the sun to wither up the weeds. Except for levelling ground and making a fine surface for small seeds, the rake is useless in the kitchen garden. We are still using Sea-kale; but it is now rather long, and cannot be kept short, still it helps to give variety, as our Broccoli is becoming scarce, and we have not many Cauliflowers, though Peas from the orchard-house have been very useful, and the little Tom Thumb, though occupying little room, yields good gatherings.

Onions.—Those planted out are doing well, and the spring-sown are far enough advanced to permit of a good hoeing between the rows, not deep, but just sufficient to destroy the small weeds. A lot sown along with Cauliflowers and Celery under protection has been useful for salads when those sown last autumn were too large.

Celery.—Pricked out a lot over a slight hotbed to bring it on quickly, and pricked out more in the open ground. We need to select a hard piece of ground, put on it 4 inches of rotten dung, cover with an inch or two of fine soil, and then prick out; but now we generally stir the ground, mix some manure with it, add 2 or 3 inches more, some fine soil on the top, and prick out about 4 inches apart. We find the plants thus treated lift with better balls, and never seem to feel the removal. In our young days we recollect of a keen discussion about planting Celery, one party contending that it was best to take it up carefully and plant without touching a leaf; another party, that it was best to trim the plants and lessen or shorten the leaves. Both were right according to the point of view. If the roots were not kept pretty entire, and if the place were much exposed, diminishing the bulk of leaves would so far lessen the surface of perspiration, and therefore give the disabled roots less to do. When the roots can be taken up unmutilated, and the slightest shade given in very bright weather, then the rule ought to be, Touch not a leaf. In practice we dock or mutilate no leaves; but if the plants are large we generally examine the base and remove every appearance of a sucker that would compete with and so far rob the main stem. When this vegetable is wanted early, blanched for soups, it is a good plan to grow some thickly, say 6 inches apart, over a gentle hotbed, and earth up with ashes. Some are content with green Celery for soups, and therefore such care would be unnecessary; but others would look on green Celery in any combination as an abomination.

Asparagus.—How few are able to practise what they know to be the best. As soon as the bulk of the gatherings is over (and never could there have been better weather for this vegetable), we would like to apply a surfacing of rotten manure, a little salt, and even a slight dressing of artificial manure such as phosphates or guano; but we fear we must wait until we have some rotten short grass. Many forget that summer is the time to mnnure Asparagus. The winter dressing, so common because the dung can be more easily obtained then and put on the ground, is of little more use at that time than helping to keep the frost out of the ground. On a small old piece intended to be taken up for forcing next season, we have only cut a very few of the largest heads, and have allowed all to grow on strong and untouched. We know we shall be rewarded by the cuttings next Christmas, or much before that if desirable.

Dwarf Kidney Beans.—The first sowings are coming through the ground all the better owing to the floods of Friday night, and the day before we planted out a piece with strong sturdy plants, which will be protected at first with old sashes, mats, &c., which will keep on the succession and afford us a good supply some weeks before the first sowings out of doors.

Keeping off Depredators.—The worst of all contrivances for the purpose is, that they generally last only a time, until birds or other depredators become used to them; but a relief even for a time is desirable, and then the modes must be varied, and the different contrivances may last long enough to suit our purpose. For instance, now that the fruit-buds are all expanded, we shall not interfere with tomtits, but bid them a hearty welcome, as they will help to keep caterpillars and other insects under. We lately stated how Cauliflowers were stripped to the ribs and backbone, and how partridges cleared off the young Carrots as fast as they came through the ground. Finding a fine pheasant's nest at the base of an Apple tree, we were led to blame the hen as well as the partridges for attacking the Cauliflowers. We put in a number of sticks over the ground so as to stand 4 feet high, placed them slanting, and to each end suspended with a string about half a page of one of our broad-sheet morning papers, which make a rare rustling in the breeze, and since then not a Cauliflower, Carrot, Lettuce, or Cabbage has been touched by such winged visitors. The whiter the paper the better it is for this purpose, but possibly the dark lines of print may have some effect.

FRUIT GARDEN.

We hoed the ground well among *Strawberries*, and would like to dose them with a sprinkling of soot and lime, not only to help the vigour of the plants, but to drive slugs and worms away. The rains of Friday will do them much good and almost insure a crop if the ground be covered with litter to keep in the moisture. The most of the kinds are now showing blossom strongly. We intended taking up a lot which we had pricked out thickly last autumn for planting now under glass; but if the weather continue fine we will not do so, as we should not gain much more than eight days, and successions in pots in the orchard-house will almost carry us on until we have fruit out of doors. Last year we had a splendid supply in four lights over a slight hotbed, and if at all hard pressed we can place

some lights over the border, from which we intended lifting, and which fortunately faces the south. It is very easy to make a glass-covered bed under such circumstances. One of the quickest ways, perhaps, is to place flower-pots back and front for the sashes to rest on, with or without a rail from pot to pot, and then a wisp of litter from pot to pot, giving air in the usual way, and taking it away early in the afternoon. In dull weather this covering with glass will be of little advantage, but in bright weather it will bring in the crop from eight to ten days earlier. In such hot weather much time was occupied in watering Strawberry plants in pots, fruit trees in pots, Figs, Vines, and Peaches, using for the purpose clear manure water, or drainings from the dunghill alternately with clear water. We also used now and then clear lime water and clear soot water for syringing Strawberries not more than half grown, and Peaches, &c., overhead, having for many years given up syringing Vines, as we cannot obtain water clear enough for that purpose. Such washings, if the water is clear, help to keep Peach trees clean, and, in the case of the soot water, assist also in giving them greater luxuriance and a better green hue to the foliage.

Clear Lime and Soot Water.—Though we have often given the modes of making these, we repeat them, to meet the request of several correspondents. For clear lime water—say for a barrel of fifty-six gallons, add a spadeful of quick lime, stir it well, and leave it for twenty or thirty hours. Then remove the thin pellicle of carbonate of lime from the surface, and use it for syringing or otherwise, but let the operator keep it off his clothes as much as possible. If the barrel should be nearly emptied at once, fill again, stir the lime well, and use as before. When filled again add more lime.

To make soot water. For a similar barrel use fully a peck of fine soot, beat it up with a little water, with broom or spatula, into a thickish paste, as then it will mix thoroughly with the water, without any dry knots. Add the water, and then add about a pound of quicklime, or as much as would lie on a trowel, and stir all well. In twenty-four hours remove the scum on the surface, and you will have a liquor as clear as brandy. This would do for watering some plants, but for syringing it should have fully a half of clear water added. When the tub is nearly emptied, it may be filled, stirred, and allowed to settle as before; but this time it will be weaker, and the next time of filling fresh soot should be added, nearly as much as at first. After several such fillings, the barrel should be emptied out, and a fresh commencement made. It is astonishing in such cases, and in that of other manures, how soon a little quicklime clears the liquid.

Cement tanks are very useful for such purposes, built under the surface line of the ground, but an old wooden barrel would be more economical. For several years we had a number of old barrels that stood on a solid platform some 6 inches above the ground level, and these were fitted with rough wooden taps, but they became so decayed that we could do nothing with them, and we could not manage either to obtain new, or rather old, oil and other barrels that would have served our purpose, though unfitted for their original use. We therefore dug a trench in the clay, put down the old barrels so as to be about level with the surface, rough-mended the worst places, daubed them with tar outside, and packed them firmly with the clay all round, running tar down by the outsides of the barrel as we did so, and the old useless barrels thus treated have done good service for some half dozen of years, and, kept full, are likely to last a long time. Any old barrel useless for much else may thus become very useful to the cottager and the amateur, from merely sinking it in the ground. Our clay gave us an advantage, but any soil the most open and sandy would do if firmly rammed when a little damp; and a few pence were spent for tar from the gasworks, which was allowed to mix thoroughly with the soil for several inches outside the barrel. We have our eye on a huge butt that had been used as a horsecart water-barrel, but which is too far gone to be of use for that purpose. The press of other matters alone has prevented its being put out of sight below ground, when we have no doubt that what is useful for nothing but firewood would do good service for ten or twenty years. However, all who can obtain them should have good barrels and tanks, and what we have not yet had, but would have were we gardening solely on our own account, would be the means of heating a tank of clear or manure water as we liked, by either having a boiler on purpose or hot-water pipes along the bottom of the tanks.

ORNAMENTAL DEPARTMENT.

After the rains on Friday a considerable amount of mowing was done, though we were behind with other work, as the ground was too wet for doing much on it. Before that we were proceeding with fresh planting hardy edgings, as Cerastiums, &c. The Cerastium died off much last winter, but even if it had not done so, it is always best when fresh planted every spring. The soil at the outsides of beds is generally in the most unfavourable state as respects air, consistence, &c., so that in making up these edgings afresh we find it a good plan to take out a spit at the sides, place that near the middle to be incorporated with the bed, and refill at the sides with better-aired and pulverised soil from the surface of the bed. This is especially necessary when the same edging is to be repeated in the same place.

Much time has also been occupied in potting Pelargoniums, pricking off the last seedling Lobelias, and putting in the last batch of Verbena cuttings, planting them out at once in light soil over a hotbed. These will make good plants to lift with small balls in little more than a fortnight. We are a little late with some of these plants, though the bulk is early enough; but though not a single foot of glass has not had its several crops all the winter, something must be late when there is a constant contest going on as to which is to be preferred, the useful or the ornamental—that which, in a word, has to appear at table to be eaten, and that which is merely to please the eye by looking at it. For all pricking-out and hardening-off processes, and where some covering at first is necessary, we have found nothing better than calico not over thick. We have covered beds of Pelargoniums and Calceolarias with this, watered when put out, and they required no more trouble than exposing them gradually a few days before planting out finally.

Finished in the meantime fresh arranging verandahs, conservatories, &c. Two correspondents have sent us a line in reference to previous remarks. One has a small lean-to house, the other a small span-roofed house, and they ask how they are to change the appearance of such houses. One having always kept the tallest plants at back, falling regularly to the front at the pathway, and the other having always kept the tallest in the centre, and the lowest at the sides, of course, in either house, whenever you open the door, you see the whole. Well, what we mean is simply this—Let such arrangements remain as they are for a week or two, and then try and arrange the plants not in a regular sloping bank, but as so many pyramids, with low valleys between them, and, perhaps, a taller plant or two in the middle of such valleys, as a point for the eye to rest on. Even in a small lean-to house, you might have two or three higher ranges across the house with lower bays and valleys between, and an infinity of plans could be adopted, which would enhance the attraction by preventing your ever seeing so much as the whole at once. Had we only one such house, and could have our way, we would fresh arrange the plants in pots every week, so as to have variety, instead of sameness, to contemplate. It is well that change and variety are so pleasing to human nature, and even the gardener will act wisely if he avoid as much as possible the stereotyped in manner and design.

Shading.—We noticed last week the spattering the glass with white-coloured water. If not enough be given at once it may be repeated, or put on thicker, or a brush may be used. Let us warn all, however, that for this shading purpose whitening or chalk be used; avoid lime by all means, if you would not injure paint or putty. We have never had shading for our conservatory; in fact, have no regular shading material for anything. Many plants taken to the conservatory had a slight shade from plants above them, as late Vines, &c., before, and therefore such a fierce sun as we have had would have been prejudicial to them. We therefore wanted a shade that would be enough for the purpose, stand until autumn, and not be unsightly, nor yet too dense for a dull day. We have tried many modes, and successfully enough, but we have found none more simple than skim milk, with a little powdered whitening mixed with it—say as much whitening as the size of a walnut—reduced to a fine powder, and thoroughly mixed with two or three quarts of milk. We would advise those trying the scheme to do a piece of glass first, let it dry, and add to the milk or whitening as they require less or more shading. We have not applied the shading mixture quite so well as usual, as it looks a little run; but if it be put on quickly and thinly by one man with a brush, and another follow with a dry duster brush, merely daubing it quickly with the points of the dry brush, the shading will have the appearance of shaded ground glass, and look neat enough for anything. The least

quantity of whitening in the milk will give as much shade as Hartley's rough glass.—R. F.

COVENT GARDEN MARKET.—May 15.

Notwithstanding the cold wind prevailing during the last few days, abundance of produce, both forced and from the open ground, is brought in by the growers. Of Peaches and Nectarines there is a good supply, and foreign imports are well kept up. They comprise Cherries, Strawberries, and Apricots, with the usual description of vegetables.

TRADE CATALOGUES RECEIVED.

William Bull, King's Road, Chelsea, London, S.W.—*Retail List of New, Beautiful, and Rare Plants.*

James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, London, and Coombe Wood, Kingston Hill, Surrey.—*Catalogue of New and Beautiful Plants—Plant Catalogue—List of Select Softwooded and Bedding Plants, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

Back Number Required.—2*s.* 6*d.* will be given for No. 169, of The Journal of Horticulture, date 21st June, 1864, by Mr. Thomas Kelly, 60 and 61, Albany, Liverpool.

Insect on Rose Trees (*E. Collins*).—The insect which has eaten the bark from the shoots of your standard Roses is a Curculio, or Weevil, and we think, from the specimens sent, C. sulcatus. Your best mode of exterminating it is to spread a white cloth beneath each bush after dark, and then shake the bush. The marauders fall on the cloth and may then be easily destroyed. This may be repeated twice or oftener every night, until no more are captured. The Grass you mention is hardy.

Orchard-house and General Garden Management.—"I happen to have a similar quantity of ground, two acres, but cannot, like 'C. P.,' make a sixteen-year-old lad and an occasional labourer, added to my own slender services, suffice to keep such a garden—at present without houses of any kind—in such order as I wish to see it. Would 'C. P.' give us some further insight into his mode of procedure; how he has laid out his ground, whether he luxuriates in much flower culture, or has much of his ground in open shrubbery? as these points materially affect the expenditure of labour. If I could work as 'C. P.' does in the management of his garden, I should not hesitate to put up orchard-houses, but at present the extra tax in skilled labour this would entail deters me. I hope 'C. P.' will be induced to favour the readers of the Journal with another instalment, that we may find his talisman and so extend our gardening operations without increasing our staff.—Subscriber."

Asparagus Blight (*J. C. D.*).—A parasitical fungus has attacked them, closely resembling Uredo fosculosum, but quite new to us. We should cut off all the shoots attacked by it before the fungi shed their spores, and apply two or three strong dressings of common salt to the bed.

Nectarine Tree not Bearing (*A. B.*).—We see no reason why in a house which becomes so hot in summer, and without artificial heat, your Nectarine tree did not ripen its wood, as well as show and set blossom-buds, though we do not think there is any gain in taking much from a tree the second year after planting. There is nothing in the character of the house to account for the tree being unfruitful, as the heat in sunny days ought to have ripened the wood in the autumn if the tree had obtained justice. Excessive heat during the summer could be guarded against by more ventilation and slight shading in the brightest days. A very small proportion of a pennyworth of whitening, if employed to colour some water white, and thrown on the glass outside with a syringe, would break the force of the sun's rays in May, June, and July, whilst the sun could scarcely be too bright to ripen fruit and to mature wood. We think your want of success has been owing to your leaving the tree to take its own mode of growth, which rendered your consulting the admirable directions of Mr. Bréhaut and Mr. Rivers of but little use to you, as whatever system is adopted it must be carried out thoroughly if success is to be obtained. Your tree was planted two years ago in fresh soil against the back wall of your house, "and last year it covered itself with long willow-like shoots—became a bush in fact." Now, if the tree was in the bush form when you obtained it, it might have been best to have continued it in that form, pinching the strongest shoots first, as Mr. Bréhaut advocates, and, after securing the necessary number of equal-sized shoots, stopping them when 15 or 18 inches in length, so as to swell the buds behind and lessen growth, as the most of the growth made afterwards would be cut away at the winter pruning. From your description, however, your tree had been allowed to take its will, and produce as many as it liked of its willow shoots all last summer, unstopped or unchecked, and so thickly, we presume, that the sun could not reach them. The fact of the leaves remaining all the winter is a proof that the wood was not ripened; and though these leaves were at the points of the shoots, and therefore of less consequence, still the wood nearer home would have been better perfected if they had been stopped in summer and thinned out so as to let the sun play upon them freely. For a good fruit-bud to be formed at the base of a leaf, the sun's rays should have access to that leaf. Again, if you had decided on the bush or even the pyramidal form, the tree would have been better planted in your border farther from the wall, so that the sun and air would have had access all round it. You leave us in doubt, however, as to whether you mean this bush form to be continued, as you ask, with this pinching on Mr. Rivers's plan, "how the tree is to get the shape I want it, and cover the wall?" The tree having had its own way last summer, most likely the gardener did quite right in cutting out in February the rankest, most luxuriant shoots, and might have gone farther and shortened the others left; but, presuming, as you say now that these shoots, though unfruitful, are healthy, and studded all over with young shoots, some 2 inches or so apart, then we would advise as follows:—If you determine on the bush or pyramidal style, allow the terminal young shoot to grow 6 inches or more before stopping, slip off with a knife fully one-half of the young side shoots coming, and stop the others according to Mr. Rivers's advice. You will not have such a thicket of third and fourth growths as you imagine, and when they do become thick you may thin them; most of them will be removed at the end of autumn. The lower part of these side shoots—those that are puzzling you now, will all be stored with fruit-buds next season if you give plenty of air and sun, and little water after September—in fact, they will be very much like your Cherry tree, which is so fruitful and needs little stopping because it is old. The stopping above referred to will make a young tree whilst vigorous as fruitful as an old one. If you mean to cover the wall as soon as possible, spread out these shoots in the fan style, leaving the centre shoot well cut down, so as to furnish shoots to fill the centre. Now, you may adopt one of two modes. First, the old mode by which the shoots formed this summer bear the fruit the next, and a fresh shoot taken from the bottom replaces them. In this case you save the young shoot that is coming from near the end of last year's shoot to continue the leaders and fill the wall, stopping, or not stopping, according to its strength, and at once you may remove about half of the other small shoots with a sharp knife, doing it by degrees, so as not to interfere with root-action, but so as to leave the young shoots on the upper sides of last year's shoots about 12 or 15 inches apart, allowing each to grow that length before stopping. On these little shoots that now so bewilder you, thus thinned, you will depend chiefly for your next year's crop. Another plan is to make your present shoots, and the terminal fresh ones now coming, the main leaders and fixtures; thin the small side shoots only half as much—say to 6 inches apart, stop these when 3 or 4 inches long—make them into short spurs in fact—and keep them as such, merely thinning them out a little when too thick. By this plan, when you fasten your main shoots to the wall, you may do all the rest without nailing, tying, or much winter pruning. By the older and generally practised mode against walls you must cut out the shoot that bears this season, and be supplied with another from its base to succeed it next year.

Burning Weeds (*E. P.*).—There is no law prohibiting the burning of weeds in a garden. If any damage is occasioned by such burning the person burning the weeds would, of course, be liable to an action to recover the amount of that damage. Although there is no law prohibiting the burning of weeds, yet if the smoke so caused is offensive to a neighbour, it would be well not to burn them, except when the wind blows in a direction from his premises.

Wireworms (*Inquirer*).—There is no wholesale mode of destroying these pests except by paring and burning 9 inches in depth of the entire surface of your garden. Frequent digging and picking them out thins them very much. Growing a crop of White Mustard is said to drive them away. Powdered oil cake about seeds when sown, or around the roots of a plant, are said to keep the vermin from injuring them.

Cucumbers not Swelling their Fruit (*H. T. M.*).—With the healthy Cucumbers which refuse to swell their fruit, your only chance is to diminish vigour by taking away some of the older and larger leaves, give less water, more air, and thin out the young fruit when young. For those you intend planting we would advise using nothing but fresh sandy loam—no manure of any kind—and if that do not give strength enough afford some clear manure waterings. Avoid in such a case rotten dung, leaf mould, and anything of the kind in the compost. These vagaries, and the different diseases which affect Cucumbers, are little understood. Young plants and fresh poor soil are the chief remedies.

Gas Stove (*H. R. J.*).—Being without a flue, it would be injurious to plants. Let no representations induce you to use it among them.

Flower-border Planting (*An Old Subscriber*).—Arrange your plants thus:—Ageratum, if tall kind, Stella Pelargonium, yellow Calceolaria, Iresine Herbstii, white Verbena, purple Verbena, Gazania splendens, Lobelia speciosa. If a ninth row is wanted have strong plants of Trentham Rose Pelargonium behind the Ageratum; but the eight ought to be ample.

Rose Leaves Blistered (*The Cedars*).—They are blistered by cold and wet. They will improve as the weather becomes warmer, and the roots establish themselves in the fresh soil. We hope you did not place the bone manure in contact with the roots, nor used it excessively.

Strawberry Scapes Eaten (*Fragaria*).—We think ants are your troublers with the Strawberry blossoms, and if so, guano will drive them away. If that do not succeed, use lime water on the ground, and if not effectual enough, mix arsenic with sugar and place it in saucers, covered with other saucers, and with a piece of lath wood across between, so that there will be plenty of room for the ants to enter without admitting any larger living thing.

Archerfield Early Muscat Grape (*Grape-grower*).—At first Mr. D. Thomson thought this Grape a much earlier ripener of its fruit than the Muscat of Alexandria, but immediately that he had proved that his opinion was not correct he announced the fact; and it is now clear that it is only a good variety of the Muscat of Alexandria, setting and stoneing more freely.

Heating a Small Greenhouse (*E. B. B.*).—Were your house not so small, 18 feet by 8, we should say, Try another Hays's stove at 60s., as one is not sufficient. If you can obtain no more than 5° of extra heat from it, of course that would be of no use in a severe night in winter; but we think you could obtain much more heat than that by burning the fuel more rapidly—that is, giving a little more ventilation. We have not had the chance of trying Hays's stove, but the commonest iron stove, with a pipe funnel from it, ought to give three or four times the heat you specify. The great danger of a common small iron stove arises from the sides becoming too hot, and parching and burning the air. You would see what was said lately in "Doings of the Last Week," as to the importance of the fire-box standing 2 or 3 inches free of the sides of the stove. Then the whole outside is pretty equally heated, and is never so warm as to much vitiate the air. Where an outside stoke-hole is no objection, on the score of cleanliness, we know of no better plan for such a small house as yours, than having a small flue below the floor, the floor tiled, and the tiles forming the top of the flue. Such an arrangement, with the flue beneath the pathway, is very comfortable in winter, as the lover of plants need never have cold feet. We hear some complaints as to the difficulty of obtaining good fuel for Hays's stoves. Of course without the prepared fuel the stoves will not answer. Try giving more air to the fuel.

Constructing a Small Greenhouse (*B. B.*).—You will form a very good idea what such a house, about 18 feet long, whether span-roofed or a lean-to, will cost, by looking at our advertising columns; but to finish it partly as a greenhouse, partly as a hothouse and propagating-house, and heat all properly with hot water, we fear there is little chance of doing all for £20. Your cheapest plan will be to use large squares of glass, and have a fixed roof without sashes, but with strong rafter sash-bars, say 18 or 20 inches apart, on Mr. Rivers's plan. If the end of the dwelling-house is long enough, then a lean-to roof, say 12 feet wide, 10 feet high at back, and 6 feet in front, would be the cheapest, as you would only have the ends and front walls to build. With plenty of heat a span roof would be the best, with the wall of the dwelling-house for the north end; and if this were 13 or 14 feet wide you could have a platform in the centre and a broad shelf or stage all round—say pathway, 2½ feet; side platform, 2 feet; centre platform, 5 feet. In the hothouse part the side platforms could be made into hotbeds, with hot water beneath them. As the ground is highest next the house, the farther end would be the best place for the boiler; and the hothouse part might as well be at that end, with means of heating that part separately, and then continuing the heat to the greenhouse part as wanted. You may heat several such houses from one boiler, provided the boiler is so low that the top of the boiler is lower than the lowest pipe in the houses. A small boiler would heat your proposed house. There will be no difficulty in heating your dwelling-house, as well as these proposed houses, from a boiler placed underground in the wash-house. To do this, however, the boiler will require to be of a good size. From a boiler so placed you may take hot water to the top of the mansion, and distribute it in the different storeys as wanted. In such a case, however, it would be as well to have the warmest end of your proposed plant-houses next the mansion, if the boiler were placed out of doors. We spoke of the other arrangement, merely because a person might enjoy a greenhouse temperature when a hothouse temperature would be oppressive.

Couch Grass in Asparagus-beds (*Greenmellow*).—You will best clear the beds of Couch Grass by taking the latter up with a fork, and if this be carefully done much of the Couch may be removed without injuring the Asparagus roots. By persevering for a year or two in forking up the roots whenever a blade of the Couch Grass is perceived the ground will be cleared, and a dressing of salt now, equal to 2 lbs. per square yard, will help to destroy the Couch. Never allow a blade of it to be seen.

Rust on Camellia Leaves (*J. B. N.*).—The leaves are affected with rust, arising from excessive moisture and imperfect root-action. The only remedy is to prevent water dripping on the leaves, and to keep the soil drier, so as to encourage a more healthy root-action. The leaves should be dusted with fresh-slaked lime and flowers of sulphur.

Pans for Bell-glasses (*A. C. C. H.*).—You may procure pans with a double ridge or ledge for the glass shades to rest on of any of the principal seedsmen, and at many earthenware shops.

Cyclamens not Flowering (*Idem*).—As your Cyclamens grow well but do not flower, perhaps you do not afford them a light and airy situation, which is all they require. No place is so suitable for them from September to the end of May as the shelf of a greenhouse, and after that an open sunny situation out of doors, the pots being plunged to the rim in coal ashes. They do well in a compost of equal parts of turfy light loam sandy peat, and leaf mould, good drainage being provided.

Cleaning Flower-pots (*W. H. Y.*).—The best plan that we have tried is to place the pots requiring cleaning in a tub, cover them with water, and after allowing them to become well soaked, say for a couple of days, to wash them well inside and outside with a spoke brush or any old or half-worn hard brush.

Twelve Greenhouse Plants for Flowering in July (*A Subscriber*).—The following will flower about July; but to have plants in flower at a given time it is necessary that they be grown specially for the purpose, and forwarded or retarded as occasion may require:—Acrophyllum venosum, Boronia serrulata, Crowea saligna major, Leschenaultia formosa coccinea, Pimelea Hendersoni, Polygala Dalmaisiana, Phænocoma prolifera Barnesii, Tremandra verticillata, Pleroma elegans, Dracophyllum gracile, Indigofera decora, and Genetyllis tulipifera.

Twelve Gloxinias (*Idem*).—*Erect-flowering:* Rex igneus, Guido Reni, Novello, Comte Didinsky, Lilas franc, and Marquis de St. Innocent. *Drooping-flowering:* Wilsoni, Leviathan, Bird of Paradise, Lady Augusta Yorke, The Gem, and Impériale Blanche.

Six Achimenes (*Idem*).—Parsonsii, Longiflora major, Carminata splendens, Ambroise Verschaffelt, Magnet, and Gem.

Planting Cannas, Daturas, and Artemisia annua (*Tyro*).—Cannas have large foliage, and attain a height of from 3 feet to 6 feet. They should be planted from 2 to 2½ feet apart if the plants are strong, or from 1 foot to 18 inches apart if small. Datura fastuosa Huberiana is a tall-growing plant, having large trumpet-shaped flowers. Being of a strong habit the plants should be placed 18 inches apart; but they will not thrive out of doors except in warm situations, and they must be strong when planted out. They attain a height of 3 feet. Artemisia annua grows 4 feet high, and should be planted from 1 to 1½ foot apart; but we consider it worthless for flower-garden decoration, Wormwood being far more silvery in its foliage and quite as stately in habit.

Lily Bulbs from Japan (*S. C.*).—The bulbs of the Lilies from Japan should be put singly in well-drained pots 7 inches in diameter, some of the roughest parts of the compost being placed over the drainage. The pots should then be filled half full with a compost of turfy loam two-thirds, and one-third leaf mould, adding sharp sand if the loam is not sufficiently sandy. If you have it you may also add one-fourth fibry sandy peat. The compost should be broken rather fine, but not sifted. The bulbs should be placed with their bases resting on the soil in the centre of the pots, and be covered with soil about an inch above their crowns. A gentle watering having been given, the plants should be placed in a light airy situation in the greenhouse. Keep the soil moist, but not very wet, until the roots start; then water more freely, and when the shoots are a few inches higher than the rims of the pots fill up around the stems with soil. Water freely until the growth is complete; then lessen the supply, still keeping the soil moist. Winter in a greenhouse, and keep the soil rather dry.

Poa trivialis argentea elegans (*Idem*).—This very handsome dwarf Grass is hardy in well-drained gravelly soils, but requires the protection of a frame or greenhouse where the soil is wet and heavy.

Tropæolum tricolorum Culture (*R. F. Wheeler*).—The plant, so far as we know, cannot be successfully raised from cuttings. It is raised from seed, and by layering the wiry stems in the pot in the early stages of its growth, by which process small tuberous roots are formed by autumn, but not always. The most certain method is from seed, and plants so raised usually flower in the third year. It is a greenhouse tuberous-rooted plant, commencing to grow in autumn, flowering in April, and dying down in summer. Tropæolum pentaphyllum is a tuberous-rooted plant requiring the temperature of a greenhouse. It is raised from seed, is a climber, and more robust than T. tricolorum.

Sowing Pentstemon Seed (*Idem*).—The seeds should be sown now in pans well drained, and filled to the rim, or nearly so, with light turfy loam. Scatter the seeds over the surface after having made it smooth, and cover with fine soil to the depth of a quarter of an inch. The pan may then have a gentle watering, and be placed in a cold frame, or on the front shelf of a greenhouse, shading it from sun, so as to keep the surface moist until the plants appear, then discontinue shading, and admit air freely. Keep moist, and when the plants are large enough to handle, prick them off in a bed in the open ground, shading for a few days until established, and finally planting out where required.

Tall-growing Lobelias (*Idem*).—Some of these are very handsome when planted out in summer, if kept well watered. We do not think them worth a place in a greenhouse, as they do so well out of doors in summer.

Passifloras for a Greenhouse (*Idem*).—The following do well in a greenhouse—Impératrice Eugénie, Newmanni, Bellotti, Shepherdi, Comte Nesselrode, and P. edulis foliis argenteo-variegatis.

Stephanotis floribunda in a Greenhouse (*Idem*).—It is a stove plant, and is starved in a greenhouse, but does tolerably well in a heated vinery. It will, however, flower in a greenhouse. Your other question will be replied to fully in a week or two.

Sulphur Fumigation of an Orchard-house (*E. S.*).—For your house 21 feet by 14 feet, you will require two pots of lime, as described by Mr. Rivers, and you may sprinkle over each 2 ozs. of flowers of sulphur.

Destroying Slugs (*Amateur*).—We find nothing equal to lime which has been placed under cover and allowed to fall of itself. This sprinkled over the whole surface of the garden once or twice a-week a little after dark, proves effectual, if its application be persevered in, a dressing being given prior to digging, and immediately afterwards. If you have tried this and found it fail, we recommend the surface to be pared off and burned. Hedgehogs do not care to eat slugs, but a few ducklings turned in now would not trample anything much, and would devour a great many. The ducklings, in conjunction with dusting of the soil at dusk after a wet day with lime, would soon clear the ground.

Lilium auratum Seedlings (*Inquirer*).—We would pot off the seedlings, placing two or three in a seven-inch pot; but if you cannot pot them off without disturbing and injuring the roots, we would defer doing so until autumn, and then pot them off singly in October. The soil we recommend for potting is one-half turfy loam, one-fourth sandy fibrous peat, and one-fourth leaf mould, adding sand liberally. The cross between L. auratum and the Scarlet Martagon will most likely produce something desirable in colour. You may exhibit Trichomanes radicans as a British Fern.

Disa grandiflora Culture (*Idem*).—This succeeds excellently in an airy and shady part of an ordinary greenhouse, it being very impatient of bright sun, though it likes light and air. It requires an abundance of water, so much so that when the plant is growing, winter and summer the pot may be set in a saucerful of water. The most suitable soil is sandy fibrous peat, with a few bits of charcoal intermixed. If the peat

is not sandy, silver sand should be added liberally. It is essential that the pot be well drained.

Parsnip Seed Eaten (*I. R.*).—The Parsnip seeds or rather husks have had their vitality destroyed by some weevil or beetle, and not by slugs as you suppose, for the seeds have never germinated. Had you scattered soot in the drills before sowing, we think the seeds would have been preserved, and as the ground is now infested with slugs, we advise you to scatter fresh lime over it at dark after a showery day.

Temperature for Muscat of Alexandria Vine (*A Young Gardener*).—The Muscat of Alexandria will do fairly in a house having a night temperature of 65°, with a slight increase during the flowering period. The temperature is not too low, forcing being commenced from the middle of March to the beginning of April, in fact, it will do well in such a temperature. There is no better variety than the Muscat of Alexandria, though the Bowood Muscat is thought to be a more free setter. The Muscat Hamburgh will succeed in an ordinary vinery, and so will the White Tokay, if afforded a little fire heat when in flower, and when the fruit is ripening. The White Tokay is a fair setter, being about equal to a Muscat in that respect. The Muscat of Alexandria does as well on its own roots as when worked on the Black Hamburgh, if not better.

Pelargonium Leaves Spotted (*O. E. S.*).—The leaves were spotted with a fungus, arising most probably from the soil in which the plants are growing being too rich and wet. The atmosphere is also too moist, and not sufficiently ventilated. Keep the soil drier, and admit more light and air. If the border is badly drained, that will be sufficient to cause the spots.

Prunus sinensis flore pleno Pruning (*Quack*).—The plant not having bloomed will have made new growth, which you cannot now shorten without placing in jeopardy next year's bloom. You may, however, cut out any straggling shoots, leaving enough new ones to form a compact plant. It should be done forthwith. The secret of a good bloom is to secure a good growth, and have it well ripened by exposure in an open, sunny situation.

Cucumber Culture (*Idem*).—Extremes of heat and cold are not good for anything, and success under such circumstances as you mention is the high road to failure. The thermometer at 105° occasionally will do no harm apparently at the time, but you may ere long see your plants die in an hour. Air should be given when the temperature rises to 80°, and even earlier; and what is meant by not exceeding 80° is, that heat must not be exceeded without air being plentifully given, which is sound practice. It is well, too, if the thermometer do not fall below 65° at night; but we have had it as low as 55°. The water used for watering will do well after this if it be warmed in the sun or by hot water.

Market Gardener (*J. W., jun.*).—We do not know any of the market gardeners who attend Covent Garden Market with their produce.

Roses not Flowering (*W. A. O.*).—Roses which have made their growth without flowering should not be cut back unless of greater length than necessary for the purpose required; but they may, if straggling, be cut back to the sixth leaf if weak, or to the eighth if strong. As regards Teas, apply to Mr. Baily, 113, Mount Street, Grosvenor Square, London.

Jasmines Shedding their Flowers (*G. P.*).—From what you say we should think the flowers continue but a short time from the house being too warm, and the roots of the plants not sufficiently moist. Perhaps slight shade would prolong the bloom. Keep them as cool as you can.

Plum Tree Blighted (*A. H. J. L.*).—The leaves are attacked by a very peculiar parasitical fungus on their under surface. Dust under the leaves perseveringly with flowers of sulphur, and have the surface of the border over the tree's roots mulched, and watered during dry weather. The Plum, we think, from your description, is the White Magnum Bonum.

White Lobelia (*W. S.*).—Your seedling Lobelia is the best of the white varieties we have seen. If compact in its habit and growth it will be a great acquisition.

Name of Vine (*Live and Learn*).—The Vine leaf, very large and downy, resembles that of the Malvoisie de Trieste, a new sort, not perfectly known in this country. It produces very luxuriant foliage, but seems unfruitful, and not likely to be worthy of cultivation.

Roses (*J. Gresty*).—We are sorry that we cannot aid you. The varieties of these and of all florists' flowers are so numerous, and many are so nearly alike, that it is impossible to name them with certainty from cut blooms. (*S. E.*).—Your specimen was too much faded to form a correct opinion. We should think it might be Gloire de Dijon.

Azalea (*A. L. X.*).—Your Azalea is very distinct from any we have seen, but the roughness of the petals is decidedly much against it. As a decorative plant it will be very useful, and had it but the smooth outline of Criterion it would be first-rate.

Names of Plants (*J. B. L.*).—Scolopendrium vulgare, Lastrea dilatata, var., Asplenium fontanum, Asplenium adiantum-nigrum. (*A. H., Uckfield*).—1, Adiantum hispidulum; 2, 3, and 4, all varieties of Asplenium flaccidum. (*Philokoidomos*).—1, Saxifraga crassifolia; 2, *a. b.* Iberis semperflorens; 3, Myosotis, sp.; 4, Saxifraga Rottlerii (?); 5, Narcissus incomparabilis (double). *Ferns.*—1, Nephrodium effusum; 2, Pellæa hastata; 3, Pteris serrulata; 4, Selaginella Martensii, var. (*J. T., Newport*).—Orchis mascula. (*W. H. M., Killaloe*).—Arabis stricta. (*E. S. B. G.*).—Sedum Rhodiola (British). (*W. W. E. W.*).—1, Salix aurita, var.; 2, Salix phylicifolia, var. (*Pant*).—Ornithogalum virens. (*E. J., Atherta*).—Nepeta glechoma. (*Bradford*).—Abies cephalonica.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 14th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE ROYAL AGRICULTURAL SOCIETY'S POULTRY SHOW AT BURY ST. EDMUNDS.

I wish before it is too late to draw attention to the excessively early date fixed for closing the entries for the above Show, being more than six weeks before the day of opening. I do so in no unfriendly spirit, as the liberal prize list must make every exhibitor desire a great success.

At the time of year fixed for the Show in question, as every breeder knows, it is peculiarly difficult to tell so long beforehand what birds will be available for exhibition purposes. Your best hens may be broody, in which case they never appear to advantage, or a thousand other circumstances may occur, which may cause the intending exhibitor to prefer the forfeit of his entries to sending his birds. Still, had this been optional, I should not have drawn attention to the matter; but many may not have noticed that every certificate contains an engagement to pay a fine of 10*s.* for every pen not sent, thus entailing a loss of 15*s.* per pen in case of not sending. Under such circumstances the long date is absolutely preposterous and unjust, the only exceptions to the fine allowed being death or disease.

Such long notice cannot be necessary, and I beg to suggest that the date for closing the list be postponed till June 15th. No objection need be made on the score of past announcements, as a simple notification in the public journals would reach, directly or indirectly, at least nine-tenths of all the regular exhibitors; and I feel assured such a concession would be received with satisfaction by all.

For myself, I would be willing to risk the entrance fee according to the usual custom; but I am not willing to enter birds six weeks and a half beforehand in the middle of summer, with an engagement to pay 10*s.* in addition if I do not send them. Unless this be altered I shall keep my fowls at home, and many others will do the same.

The intention of the fine is evidently to secure a good show; but will have just the contrary effect now attention is drawn to it. The Committee have simply, with the very best intentions, made a mistake through want of practical experience in poultry-show matters; but we must all, for many reasons, desire to see such a prize list as they offer well supported by exhibitors, and I hope it is not too late to have the mistake rectified. It may assist in this if others will express their opinions.—Nemo.

[We consider this is worthy of the immediate consideration of the Society's Council. Time is needed for constructing the pens, therefore without altering the date of entry, it might be sufficient to announce that no fine will be imposed.—Eds.

BRAHMA POOTRAS.

Though never a breeder of these birds, yet as a fair judge of poultry in general, I may state the following:—

The pea-combed Brahma Pootras were first produced from

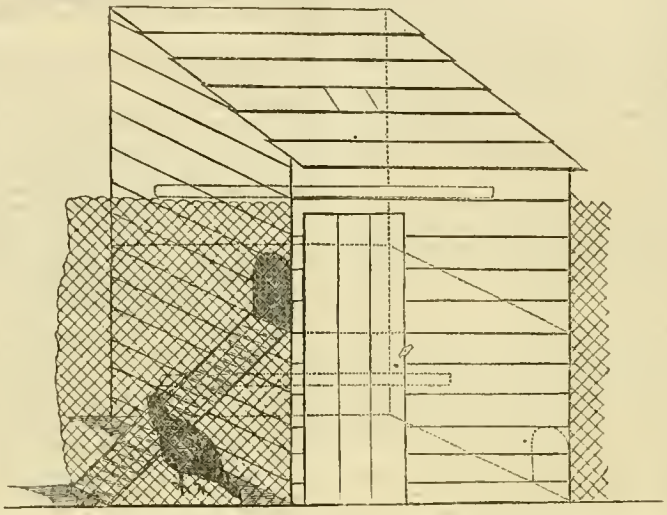
the Birchen-Grey Malay cocks, crossed with the Cochin-China or Shanghae hens. This cross gives the pea-comb and takes away the vulture hocks, and it is in this way they were first bred in the United States, I have heard.

There is no Dorking cross at all in Brahma Pootras. The pure Brahma Pootras are only the Birchen Grey breeds of the Shanghaes and Cochins, and have the straight or single combs, with vulture hocks. They are to be found pure in India and Burmah. The Malay cross gives the Malay expression to the head.

Brahma Pootra hens are rather less prolific than the hens of the Shanghaes or Cochin-Chinas. If a Dorking cross exists it has been made in England, of course.—Trevor, *otherwise* Newmarket.

PORTABLE POULTRY-HOUSE.

I enclose a sketch of a portable poultry-house I built last summer, and which has successfully answered its purpose. It is in five pieces, and can be taken down and put up by any carpenter in a quarter of an hour. The back, front, and sides are fixed together by eight bed-screws, the top also being screwed on. It is 8 feet high behind, 6 feet in front, the interior consisting of two compartments, 6 feet square, and the cost about £6 10*s*.



In the top compartment I kept five Dorking hens and a cock; in the bottom, eight Cochin hens and a cock. They were placed in the house last June, and, notwithstanding the severity of the winter, are all in good health, and have laid an average number of eggs. My garden is 33 feet wide, and the poultry-house is in the centre of a strip at the end 6 feet deep. You will observe I am enabled to keep two varieties distinct, the Dorkings from the top compartment running about 14 feet one way, the Cochins from the bottom a similar distance the other. I had it painted with Carson's anti-corrosive paint, and have never yet found water make its way into the interior.

By using this house I have found that with a limited space I have been enabled to keep some fifteen fowls in a healthy condition, and have been constantly supplied with new-laid eggs through a most trying season at a cost of not more than three farthings each, whilst the price charged in my locality —north of London—has never been less than 2*d*. each, and they were not always to be obtained when wanted.—S. F. A.

POULTRY SHOWS AND THEIR MANAGEMENT.

À propos of the Woodbridge Poultry Show.

Honesty is the best policy in every sense. Give a certain gentleman his due, for he is not so black as he is painted. So much for proverbs. We all remember the proceedings of the Woodbridge or Suffolk Poultry Society last year. To say the least of it, they were suicidal. I had my kick at them because they deserved it. Now I hold out my hand in friendship for the same reason.

They found themselves incapable of paying their debts, and they either had not the moral courage to say so, or they robbed Peter to pay Paul, giving a preference to some prizetakers to the exclusion of others. Moreover, they were not civil; and because letters were difficult to answer, they solved the difficulty by leaving them unanswered; but Peter was true to his name and firm as a rock. He meant to go share and share alike with Paul, and he obtained—at least I did—all he asked for.

"Well," says Common Sense, "then what more can you have to say?" I reply, A great deal. But the weather is hot, and times are hard, and many engagements last year in weightier matters than a poultry show were not punctually met. Pigeon shows, by the way, were rather in fashion in the City; so we will let bygones be bygones. The fruit trees are in blossom, the nightingale and cuckoo in full song, chickens are chirping, Pigeons are chirre-ing, and we are all thinking about flower and poultry shows. We cannot help being good-tempered, and we have no reason to be otherwise with the Woodbridge people; for those who have been paid their prize money, as I have been, have no reason to grumble, and those who have not been paid have, without doubt, received the following notice, which has been sent to me:—

"All persons having any claim or demand upon the above Society in connection with the Poultry Show held at Woodbridge on the 24th of May last, are requested to send the particulars thereof forthwith to Mr. John Dallenger, Public Accountant, Thoroughfare, Woodbridge, in order that arrangements may be made for their full and effectual discharge."

This is an announcement which ought not to be passed without a notice. It is the declaration of an honest man. If a poultry show should be held at Woodbridge this year—and I hope one will be held there—the promoters need not now fear but that they will be well supported. Having done wrong, they must now do right.

As to poultry shows generally, unless prize money is paid punctually and within a short time, regardless of the receipts and expenses—unless the whims, the fancies, and the interests of local exhibitors are swamped in arrangements for the general good—unless all is fair and aboveboard, and for the specific object of encouraging and improving the breed of poultry—such exhibitions, now rapidly increasing in number, will as rapidly diminish. We have really very little to find fault with in the management of poultry shows generally. They are a labour of love, and could never pay the managers if they made a charge for the time expended. The judging is for the most part fair, in spite of the grumbling of the unsuccessful. Exhibitors are by no means immaculate, and in some cases do not set either judges or committee men a good example. Let us all try if we cannot this year be honest, forbearing, good-tempered in defeat, and unselfish, so that a general good be obtained; and let us strive to promote a straightforward rivalry in exhibition, where nothing but dame Nature, judicious breeding, and feeding, shall put our birds in a foremost place, and make our poultry shows no longer exhibitions of the fine arts connected with scissors, files, tweezers, and thread.—Ecomet.

UNPRODUCTIVE PURCHASED EGGS.

Seeing in The Journal of Horticulture some eggs from White-crested Black Polish fowls advertised for sale in Hants, I wrote for a sitting, which in due course I received, and for which I paid 10*s*. 6*d*., exclusive of carriage. The eggs were placed under a hen sitting in a house with six others; at the end of the term there was not a sign of a chick in any one of the Polish eggs, but all the other six hens sitting in the same

house and under exactly the same conditions hatched out. There was not a fault to be found with the hen under which the Poland eggs were placed; I never in my life saw a hen sit better. I may remark that the eggs under the other hens were *not* purchased eggs. I wrote and stated the result of the sitting, but received no answer whatever. It is not to be wondered at that persons are becoming shy of purchasing eggs for sitting when the results are so frequently unsatisfactory. It is strange that poultry breeders cannot see that they are ultimately injuring themselves by not being more careful with the eggs they sell.—POLAND.

BREEDING POULTRY.

READ BY COLONEL HASSARD BEFORE THE CANADA WEST POULTRY ASSOCIATION.

IN regard to the mode of rearing chickens, much may be learned from books on poultry; but there is one subject on which they are silent—viz., impregnation. I had heard and seen that many fanciers and breeders, in this country especially, allow all breeds to run together at certain seasons. They say it is convenient to do so if the cocks agree, and if eggs are then taken they are useless. Granted; but after this promiscuous running together can you be certain that no future harm will arise from it? In the larger animals, such as cows, horses, and others, there is no doubt that the first impression lasts for some three or four births. A nobleman in England put a thorough-bred mare to a zebra: the offspring was striped. The next year he put the mare to a thorough-bred horse, and again the stripes appeared; and I am informed that for three or four foals all were more or less striped on the shoulders. Some years since, when in the Mediterranean, I had a pointer bitch, of which the greatest care was taken to keep the breed pure; she had a splendid litter of puppies, eight in number; I reared six; they were all pointers but one, which, though of the same colour, turned out a long-haired, ugly brute, almost useless. This was accounted for by the fact that the first litter had been by a vagrant in the street, similar in shape, but of different colour to the odd pup. I therefore recommend to all poultry breeders to keep their birds pure; above all, not to let the pullets that they intend to rear stock from have any intercourse with males not of the same breed. Perhaps some of the professional and scientific men in the Society can explain these things, which I do not profess to be able to do. I merely state the facts, and act accordingly. I never let any pullets of mine run promiscuously with other breeds: and I think what holds good in one case, will in another.

With regard to breeding, I think that the system of counteraction must be acted upon. I merely say I think, and do not lay down the law on the subject; but I am convinced that in breeding Pouters, Carriers, Cochins, and other breeds, to do well you must always act on this principle, which I will explain. It is valuable information to many, and breeders generally would have better stock by paying attention to the rule. It is this:—Supposing (take Carriers for instance) you have two first-class birds which you want to match, but on examining the points, you find both deficient in one point—say eye; you cannot match them, or you will perpetuate bad eyes—the very thing you want to avoid. No, you must select a bird with a very good eye, to counteract the deficiency in the other, although it may have some other inferior point. Again, in Pouters, if you have one of great length, you could afford to match it to one smaller, if good in other points. Again, in Cochins, if you want good colour, all other things being perfect, a dark cock should be put with light hens, and *vice versâ*—you will then get light and dark chickens, but never mealy or of doubtful colour. In a show pen it is quite the reverse; the birds must match in colour to a nicety. I have merely given these examples because they have come within my own experience; but in all other breeds the same thing applies: so that it appears there is a great deal to be studied and thought of, and attended to, even in breeding poultry. Here I should state something about breeding in-and-in, or from near relationship, which if continued will eventually ruin the stock. Mr. Ballance, of Taunton, Somersetshire, has, however, proved that by a judicious selection of strong birds from different broods, kept in different runs, the system may be successfully carried out; but there is no doubt that, if continued for many years carelessly, the stock degenerates. In a manufactured breed, like Sebright Bantams, it cannot be carried on at all, or degeneracy in markings, &c., will be at once apparent.

The next question is, What are the best ages to breed from? I have been compelled to breed from young stock generally; but I believe two-year-old cocks and young hens, or the reverse, would be equally good. So much depends upon what one has, that no rule can be always followed; and if the stock is healthy and not too old, and the aforesaid principle of counteraction attended to, the result should be good. For all sorts, get birds as nearly perfect as can be, and never breed from stock with glaring defects on one side or the other. I think that these rules should be followed until the breeder has a good stock on hand. He may then try experiments by crossing; but there is one thing he never should do—that is, sell any of this experimental stock as the genuine article, or at any rate without letting the purchaser know what he is taking. I once in England sold a gentleman a Black-breasted Red Game Bantam cock; he was satisfied in all respects but one; he said he thought he could trace on the wing a light portion that made him imagine he had Duckwing blood in him. I wrote immediately, and told him that one bird in the brood had turned out Duckwing; he asked me to take him back, which I did; but I was not obliged to do so, as there had been no deception on either side. At the time I was not aware that it mattered, nor did it much; for the bird was a splendid specimen.

A word or two about prices of birds of the same stock may not be out of place. Prices must vary according to quality, although birds are of the same stock. If you sell a pair or trio almost faultless, which the buyer may exhibit against you, you must get a remunerative price. You can let them have the same race, blood, purity, &c., for a less sum; but then there may be a difference in age, in points, or other respects, which lessens the price. I once purchased, from one of the first and best breeders of Cochins in England, a cock Cochin-China; the sum paid was, I think, £1 10s., which, for a bird coming from this yard, I considered very little, especially as my new purchase was own brother to the bird that had won the first prize at the Crystal Palace Exhibition. On his arrival, I did not like the comb. I wrote and said so, and I was told that a few weeks before he had a fight through the wires, and it was damaged. This I could see was the case; there was no fault in the bird for stock; but he was useless to exhibit. Had he not been so, I suppose £5 would not have bought him. Some of his descendants are now here. I merely refer to this to explain the reason why prices should vary for birds of the same stock, although they may be equally good to breed from. In closing these remarks, I would request all interested in our Society to endeavour to inculcate as far as possible into the minds of dealers and others that in poultry, as in other things, honesty is the best policy, and that no confidence can be established amongst us, especially when at distances apart, unless the birds advertised or sent are what they are represented to be.—(*Canadian Farmer.*)

HYBRIDISATION.

THE question of hybridisation to which Mr. West has directed our attention, is, as I have remarked, a very interesting, but it is also, I think, a very complex one. I do not think that Mr. West can be fairly charged with expressing any definite views, or adopting any particular hypothesis on the subject. His whole object evidently has been to elicit information and stimulate inquiry. I should be happy if I could assist in this laudable object; and with this view I now desire to add a few words to what I have already said upon it in the Number of the 7th of March last. Judging from the few replies called forth by Mr. West's appeal, the subject has not been apparently much studied.

Although in the article to which I have referred I hinted that the queen's mating with more than one variety of drones might afford a certain solution of the results of hybridisation, yet I must confess that my observations with respect to the queen herself, in certain peculiar circumstances to which I need not here more particularly allude, would rather tend to disprove the theory of double matings altogether. Again, in remarking upon the rapid deterioration of the pure Ligurians in most apiaries, I only expressed, I believe, the general experience in the matter. I also stated that in circumstances where, from the immense number of Ligurian drones in proximity, a true impregnation was probable, the results nevertheless were often unsatisfactory and puzzling. In making

that statement I by no means adopt the theory that this object is more easily attained, as some seem to think, when the drones are distant some miles. Indeed, I am not satisfied that we have yet sufficient evidence that, in this country at least, impregnation takes place at the extreme distances mentioned. A circle having a radius of five miles, is equal to ten miles in diameter, or thirty miles in circumference. How small, apparently, seems the chance of two solitary bees, starting five miles apart, meeting in this large area! Even though the flight were from opposite directions in a straight line, it would embrace, at the least, a distance traversed by each of two miles and a half. Be this as it may, I would reckon the chances of an Italian queen's true impregnation in proportion to the number and proximity of Italian drones. Moreover, I do not see that we have sufficient grounds for supposing that the "chances are always largely in favour of a cross."

Again, when I said that according to the doctrine of parthenogenesis a Ligurianised apiary should not deteriorate even in circumstances where impurities manifest themselves—a restoration to its normal condition in the absence of all foreign influence being only a matter of time—of course I reckoned upon any slight taint virtually disappearing before surrounding purer influences. Strictly speaking, however, absolute purity could never be attained; for once a taint exists, no power in nature can ever eradicate it wholly. Nevertheless optically, if not actually, any slight taint would be purged out by such agency.

I do not well perceive Mr. West's argument as to the selection of a particular larva for the future queen. If he has in view a pure stock, then no larva can be present in it which would develope into a doubtfully-marked, far less a black bee. If an impure stock is referred to, the particular larva selected would only affect the colour of the queen reared from it, but her better colouring would be no guarantee that it should be transmitted to her offspring.

The effects of breeding, according to strict rule, might be stated thus: If we breed from a pure Italian queen, crossed by a common black or English drone, the process of deterioration will be very rapid, by the same drone influence being continued, and, consequently, the first queen will be represented by a half, the second by three-fourths, and the third by seven-eighths impure. In the third generation, therefore, the queen will retain very little—one-eighth only of the Ligurian element, and her progeny again will retain still less. Here the deterioration is a constantly increasing one until, optically, the Ligurian element will entirely vanish. Starting with a half-bred queen, and always with the aid of pure Italian drones, the queen's purity would increase after this fashion—namely, ½, ¾, ⅞, 7½/8, 7¾/8, 15½/16, 15¾/16, &c., so that in seven generations, reckoning three generations being accomplished artificially each season, we would thus attain a purity of the queen as represented by 15¾/16, a pretty fair advance in the ascending process of Ligurianising. Still, as before stated, though we should proceed in the same way *ad infinitum*, we should, perhaps, never reach absolute purity. Like a person journeying from a point A to another point B, and by each successive move accomplishing a portion only of the distance beyond, however near he might attain the desired goal, he could of course never reach it; like the terms of an infinite series, the process is never exhausted.

But after all the question will, perhaps, be put, and it is quite a pertinent one—What is meant by purity in the Italian bee? How is it defined? What are its characteristics? Is it to be estimated by colour alone, or by colour and form? Is the worker to be the only test; or must we have regard to the queen also, and to the drone? For my own part, I can only say in answer to all this, that my experience is full of anomalies. My purest queens—these, for instance, I had from Mr. Woodbury—produced beautiful workers but indifferent drones. The queens themselves, too, were less highly coloured than some reared from them; while, on the other hand, subsequent queens that bred worse workers than the original queens, yet produced more beautiful drones. Nevertheless, my own idea of purity would be good colouring in all the three. At all events analogous dealings with respect to animals would lead us to select the best type of queen and drone to breed from. The Germans seem to hint at this, and, I rather think, try to carry it out in practice. Mr. Woodbury has had much experience in this matter, and from his known ability and great success in preserving the purity of the race for so long a period, any testimony coming from him would, I am sure, be highly appreciated.

Then as to hybrids. How are we to ascertain them? Of course there is no difficulty where the English or black element manifests itself in conspicuous characters; but there are certain close approximations to purity in the first generation not so easily determined. For instance, one queen I reared from the original pure one was more beautifully coloured than her parent, and her drones also were very superior, but her worker progeny, though all pretty well coloured and not a dark bee amongst them, were evidently inferior and inherited a taint, however slight, which increased more manifestly at the next remove. The ordinary observer might have a difficulty in noticing the difference, yet there it was and no mistake.

So far as my observations have gone, I have never found a queen's progeny, pure or hybrid, alter or vary in character. It remained the same during the queen's life. Nevertheless, there are differences in the offspring of different queens, hybridised apparently in a similar way, which appear to me inexplicable; but, perhaps, we should not after all attach too much importance to this want of uniformity, for we find analogies every day as respects other animals, the progeny in one case following more after one parent, and in another case after the other. Close and careful observations are needed in all our investigations after truth in this matter, but even then we may probably find that this is a question in nature lying beyond the ken of human knowledge, involving in its consideration constitutional and other latent causes which we can never explain.—J. Lowe.

OBTAINING ARTIFICIAL SWARMS WITH FRAME HIVES OF DIFFERENT CONSTRUCTION.

If "J. C. A.'s" Woodbury hives contain compound frame-bars, he may, I should think, overcome his difficulty by following the plan adopted by myself in making artificial swarms in frame hives of any construction with the aid of brood comb taken from a Woodbury compound frame-bar hive. I take a Woodbury bar of brood comb out of the frame, pierce the end of it with an awl or gimlet, insert a French nail (the head of which has been previously flattened), just so far into the end of the bar as to make it of the required length. The object of flattening the head of the nail is that it may rest steadily. I apprehend that none of "J. C. A.'s" frame hives are of less dimensions from front to back than the length of a Woodbury bar when taken out of its frame.

I have adopted this plan even with square Stewarton frame hives with slides between the bars, pasting the open parts over with brown paper, and in this state a very weak swarm of last year has stood the winter under an open shed. During even the most severe frosts of the past winter I did not cover up any of my hives, some of which are of the lightest description, one being a Woodbury super not more than half full of comb, and out of eleven stocks not one has suffered from exposure to the intense cold. All were under open sheds with a northern aspect.—M. S.

OUR LETTER BOX.

Weight of Eggs (*W. Thompson*).—Spanish eggs usually weigh 3¼ ozs., and these are as large or larger than these of other pure varieties; but we were shown recently some eggs of a cross-bred fowl that weighed 3¾ ozs. We may notice this cross after we have seen the hen.

Turkeys not Paid for (*H. B. L.*).—You have an easy remedy; ascertain, by writing to some one at Camberwell, whether there is such a man in Park Street, and if there is sue him in the County Court.

Poultry-keeping (*E. L. L., Wolverhampton*).—For full information on the subject of the different breeds of fowls and their management, we recommend you to consult the "Poultry-keeper's Manual," published at our office, price 7*s.* 6*d.*

Snails for Ducks (*E. S.*).—There is no doubt that snails and slugs would be a fattening diet for Ducks, but we never heard of their being employed specially for the purpose. The plant enclosed seems to be a luxuriant specimen of chickweed, but we cannot be certain without seeing its flowers. Do not be misled by the name into the belief that it, chickweed, is particularly liked by poultry.

Canaries Footless.—I have just hatched two Canaries which are deformed, being without feet, the legs being mere stumps. Can you account for this?—Lex.

[It can no more be accounted for than why Miss Biffin was born without arms.]

Preventing Second Swarms (*W H. J.*).—No extension of room can be relied on to stop the issue of a second swarm. Mr. Woodbury has frequently supplied queens at the price named, but may not at all times be in a position to do so.

WEEKLY CALENDAR.

From observations taken near London during the last forty years, the average day temperature of the week is 67.2°; and its night temperature 44.1°. The greatest heat was 91°, on the 28th, 1847; and the lowest cold 25°, on the 29th, 1864. The greatest fall of rain was 0.97 inch.

MERITS AND CULTURE OF HARDY PERENNIALS.

HERBACEOUS plants have for some years been almost discarded from the flower garden, their place being supplied by plants of tender habit exhibited in masses of one kind or colour; and to such an extent has this replacement been carried that the mere mention of the herbaceous border causes a smile. By many gardeners herbaceous plants are looked upon as well enough in a shrubbery border, and in some prominent situation in the flower garden when nothing better can be had; whilst to many they are only known by name, and yet these too often are most extravagant in their denunciation of them. The advocates of the new system are fully justified in banishing herbaceous plants from beds or borders where the disposition of the ground is geometrical or symmetrical; but their objections to such plants having a place at all in an irregular flower garden seem to me to be quite indefensible. It is all very well to have gardens wholly planted for effect; it is, I admit, the most beautiful and attractive mode; but is there no beauty in the flower of the herbaceous plant? Has it no charms of scent, of form, and of colour? It may be asked, Are herbaceous borders in winter uninteresting? I contend that even then they have an interest which bare earth, such as results in the bedding-out system, never gave. Even many of the most ardent admirers of the massing system now seek to maintain its superiority by pressing into their service those hardy perennials capable, from the character of their foliage or profusion of bloom, of superseding plants which are ill suited for enduring the vicissitudes of our climate. The most beautiful and enduring, as regards wind and rain, of the plants used for massing are old favourites, and many of them hardy perennials; and I am persuaded that with a return of the latter to their legitimate place in gardens we shall find their numbers rapidly increase, and the labour and expense of wintering bedding or tender plants considerably lessened.

The culture of hardy perennials would seem to many to be one of the simplest of garden matters, if an opinion may be formed from the position usually assigned to them. Any out-of-the-way place is thought good enough for herbaceous plants, and very often we find them associated with flowering shrubs, or a border is devoted to them with forest trees at the back. As a consequence many plants of the best species die off, and being replaced by others less choice, whilst the exhaustion of the soil is still going on, the appearance of the border rapidly deteriorates. Partly from the unsuitable situations in which herbaceous plants are placed, and in part from the little care bestowed upon them when in a favourable one, the impression has been made on many that these plants are poor at their best; many, too, do not care for them because they are not interested in plants, all they want being abundance of gaudy flowers when everybody has masses of red, white, and blue.

I do not wish to run down bedding plants or the system of planting in masses, but to point out a means of rendering that system more attractive, and affording greater enjoyment than at present, by reducing the space devoted to them, filling the beds better, and having the plants and all about them in higher keeping. On the other hand, it is foreign to my views to set up herbaceous plants as superior to bedding plants. These are most fitting for geometrical gardens, and the borders adjoining should be filled with kindred subjects; but to thrust into borders whose surroundings are of a different style a class of plants well suited for geometrical groups seems to me a want of taste. Hardy perennials are not recommended for a parterre or geometrical group, but I strongly advocate devoting a border to them wherever it will not interfere with the system of grouping; and such a border, I am convinced, may not only be rendered gay, but will be very interesting to many from a variety of flowers unfolding their charms day by day in succession for a large part of the year.

The place for a mixed border or group of perennials is not the beds or borders of a geometrical or architectural flower garden; these are for groups or masses of profuse-blooming spring and summer-flowering plants. As regards such no alteration should be made, except by concentrating the materials and labour wasted in extending the system to unsuitable positions. "Where, then, are we to have our groups and borders of hardy perennials?" The answer is simple. "Have you no other ground besides a geometrical flower garden?" "No." "Then you have no place for hardy perennials; do not attempt to grow them." "Yes, I have a long border by the walk leading to the kitchen garden;" another has a border by the side of a walk round an irregular flower garden, a third has a border, and another all these and beds in addition, which are filled, and often very badly, with bedding plants, but not because they are necessary for the design or surroundings, but simply because it is the fashion. Now these positions may or may not be suitable for hardy perennials; for, 1st, The situation should be open, not shaded by trees, or but partially shaded by those at a distance; 2nd, It should be sheltered from winds by a wall or trees at a distance, and should not be bleak; 3rd, The soil should be good, deep, and well drained, and not occupied by the roots of trees and large shrubs. If the borders have these essentials herbaceous plants will thrive in them; but if they are open and bleak, the choicer kinds will not grow well, and if shaded only plants requiring shade will succeed. If the soil is occupied by the roots of trees or large shrubs, only the commonest and more robust species should be planted.

The situation of a border for herbaceous plants may have any aspect. I write solely from experience, having found a majority of them thrive in a north border as well as and even better than in one with a southern aspect. If not

planted too near the base of a wall or fence, they do as well on its east side, exposed to the morning sun, as on the west side with the afternoon sun; and they are not affected by any ordinary vicissitude of our climate, if they have the shelter of a wall, hedge, or belt of trees, which, whilst it affords them protection from wind and cold, is not so near as to deprive them of the sun's rays, expose them to drip, or rob the soil by roots extending into the border.

The most suitable soil, being that in which a majority of the species thrive best, is a good, moderately light, sandy loam, from 18 inches to 2 feet in depth, and if there is a bed of gravel beneath all the better. Any good ordinary soil will, however, grow them well, but it must be well drained, and trenched to a depth of not less than 2 feet. If it is heavy a quantity of old mortar rubbish, sand, and cinders should be mixed with it; whilst if it is of a very sandy nature a dressing of manure will be advantageous. Many of the species, to succeed well, require a particular description of soil, which is best afforded by filling the holes with it at the time of planting. Some require calcareous soil, which is best secured by mixing with the soil of the border, at the places where they are to be planted, chalk broken rather finely, or old mortar rubbish; and in a similar manner peat, grit, or sand should be added as may be necessary. If the soil of the border is altogether unsuitable to the particular plant, remove the soil and replace it with some of the proper kind. A few species require very well-drained ground, and that should be afforded by placing a one-foot layer of brickbats or stones beneath the soil at the spot which the plant is to occupy. Some additional hints on soil will be given along with the names and descriptions of the different plants.

The planting of herbaceous plants is in a great measure regulated by the height they attain. The tallest should be placed in the back row, and others gradually diminishing in height towards the front or walk, along which should be planted the lowest growers, or those from 6 to 9 inches high, and not exceeding a foot. Hardy perennials vary in height from 6 inches to 6 feet or more: hence a border of them may contain as many as six rows of plants, and the distance between the rows and plants in each row should be equal to the full height of the plant; but as this would be too great a distance for the tall and pyramidal kinds, unless some half-hardy plant, such as Dahlias, were placed between them, they may, when the habit of the plant will permit, be planted more closely together. The plan which I as well as some others pursue, is to plant, at 6 inches from the edging, and 1 foot apart, a line of clumps, consisting of Snowdrops, Winter Aconites, Crocuses, and Siberian Squills, being careful to mix the colours; and as the foliage decays in summer advantage is taken of this circumstance to sow a line of Mignonette in April, which will take the place of the spring plants in summer, and make a fragrant edging to the border. The next row is 1 foot 6 inches from the edging, and consists of early spring and summer flowering plants not exceeding 1 foot in height. The third row is 18 inches from the second, and consists of plants not more than 2 feet in height, herbaceous Pæonies predominating. The fourth row is 2 feet from the third, and consists of plants attaining a height of 3 feet; the fifth row, 3 feet from the fourth, is for those growing 4 feet high; and the sixth and last row, 4 feet from the fifth, serves for the tallest-growing sorts. A border for perennials should therefore be 12 feet from the walk or edging to the last row, and that should not be less than 3 feet from the background, whether it be wall, hedge, or shrubs. For borders of greater width I would not exceed the number of rows, but allow more room between them, and plant a line between each of hardy and half-hardy annuals. The borders, of course, may be of any width, but the number of rows and the distance from plant to plant should be proportionate to the width of the border.

The best times to plant herbaceous plants are from the third week in September to the 1st of November, and from the middle of March to June; but preference should be given to early spring planting. It should be done during showery weather if possible, and yet it is far better performed when the ground is dry than when it is wet and cold. If dry weather set in after planting the plants should have a good watering at the time, as well as occasional waterings afterwards. During dry periods a good watering of the whole of the border will encourage growth and prolong the flowering, one good soaking being of greater service than a dozen sprinklings.

As regards support, which some of the plants require, it should be afforded early, and nothing is so good as iron stakes. These should be of various sizes and heights—viz., 2 feet and 2 feet 6 inches long, of quarter-inch wire; 3 feet and 4 feet long, of three-eighth-inch, and 5 and 6 feet long, of half-inch rod iron. All should be pointed, and 1 foot of the lower part painted with three coats of red-lead paint, the upper part receiving a priming of red lead and two coats of green paint. These are the most durable stakes that I have used. The next best are those made of Pitch Pine, which, being straight, tough, and free from knots, makes good stakes; they should be varnished. The canes of the Bamboo are also good, and so are rods of red deal, the part thrust into the ground and 3 inches higher being slightly charred over a wood fire, and whilst hot dipped to the extent charred in boiling coal tar. The upper part will of course require to be painted green.

The plants should be staked in good time, for it does more harm than good to tie them up after they have fallen down and rested on the ground. Those which have many small stems should not be tied up like a sheaf of corn, but have three or more stakes put in around them, and the tying material passed round these, so that the stems may rest against it. Plants with strong stems should have a stake to each, and in all cases they should be tied loosely, at least until they have attained their full growth. More than two or three stems should never be tied to one stake, and anything like a bundle should be avoided, as it destroys the effect and impairs the blooming qualities of the plant. The plants should be gone over every week or ten days, in order that all those requiring it may be staked or tied before they are damaged by wind.

The border will require attention as regards weeding, and should be frequently hoed and gone over to remove decayed foliage. If any troublesome-rooted weed, such as Dandelion or Couch grass, make its appearance it should be forked out, and if it has found its way amongst the roots of the plants a duplicate of the species or variety should be obtained and the plant taken up and freed of the roots of the weeds. In autumn as the foliage decays the plants should be cut off close to the ground, but not until their tops are quite lifeless. From any of the evergreen species having the foliage injured by frost the dead part should not be removed, as its remaining over the winter will serve as a sort of protection to the crowns from frost.

Early in October, during mild dry weather, the border should have a general trimming. All plants that have grown too large should be reduced in size unless wanted for propagation, in which case it will be best to take them up and divide them. Any that have raised themselves out of the ground so as to expose their roots, as is often the case with Primroses, Auriculas, &c., should be taken up and planted deeper in the soil. The evergreen kinds should not be disturbed in autumn but may be lifted in spring, and if necessary divided then, always provided it is not their season for flowering. The herbaceous and bulbous plants are best divided in autumn, as if it is done in spring when they are recommencing growth they are considerably weakened for the season's bloom. Towards the end of November a mulching of leaf mould from 1 to 3 inches thick should be applied, a peg of heart of oak, 1 inch square and 15 inches long, being placed by each of the bulbous and herbaceous plants to show their positions when the borders are being dressed in spring. Early in March the ground around the plants should be broken fine with a steel fork, and if the soil is heavy it should likewise be forked up in autumn before mulching it with leaf mould. The mulching should not be placed over the evergreen species, but be put closely around them. The bulbous and deciduous plants may be covered.—G. Abbey.

(To be continued.)

HOEING AND STIRRING THE SOIL'S SURFACE.

I observe in the Journal every week, in "Work for the Week" great stress is laid on the importance of constant hoeing in the kitchen garden. Whenever I try to impress this on any of my neighbours, they object to it as "letting in the drought" and say that except to destroy weeds, the less light land is hoed in summer, the better.

Our land is a light very sandy soil. Do you think it correct to keep the surface of such soil constantly open? Would it be better to keep the surface firm as my neighbours advise?—A Suffolk Subscriber.

[Beyond a doubt, the best practice is to keep the surface of the soil loose, whether that soil be light or heavy. The following extract from "Johnson's Science and Practice of Gardening" explains why the practice is beneficial:—"Hoeing is beneficial in consequence of its loosening the soil, as much, or more, as

by its destroying weeds. Moisture abounds in the atmosphere during the hottest months, and it is absorbed and retained most abundantly by a soil which is in the most friable state. Professor Schubler found that one thousand grains of stiff clay absorbed in twenty-four hours only thirty-six grains of moisture from the air; whilst garden mould absorbed in the same time forty-five grains; and fine magnesia seventy-six grains. Then, again, pulverising the soil enables it better to retain moisture absorbed. This we demonstrated some years since; and the reason is, obviously, because a hard soil becomes heated by the sun's rays much more rapidly than one with a loosened texture. The latter is better permeated by the air, which is one of the worst conductors of heat. We are glad to find our opinions confirmed by so practical and so intelligent a man as Mr. Barnes, gardener to Lady Rolle, at Bicton Gardens, Devonshire. He says, 'I do not agree with those who tell us one good weeding is worth two hoeings; I say, Never weed any crop in which a hoe can be got between the plants; not so much for the sake of destroying weeds and vermin, which must necessarily be the case if hoeing be done well, as for increasing the porosity of the soil, to allow the water and air to penetrate freely through it. I am well convinced, by long and close practice, that oftentimes there is more benefit derived by crops from keeping them well hoed, than there is from the manure applied. Weeds, or no weeds, still I keep stirring the soil; well knowing, from practice, the very beneficial effect which it has.'"]

VINES AND VINE BORDERS—NATURAL TEMPERATURES.

In my last I endeavoured to show Mr. Wills that off-hand remarks are not argument, and that they do not help to throw much light upon a subject under discussion, though they may sometimes be taken up and turned round in a manner the writer never contemplated. In this paper I shall try and answer "H. S."

Ever since I read that the orchard-houses at Sawbridgeworth conferred upon their occupants all the advantages of the climate of Toulouse, I have been trying to find out what that climate is, and to this day without success. When, therefore, I read in "H. S.'s" letter (page 274), this remark, "that in saying the 45th degree of north latitude enjoyed a mean temperature of from 70° to 73° during the summer months, he was only giving a fact that every gardener ought to be acquainted with," I was led, I was going to say for the hundredth time, to wish that information upon these subjects was more easily obtained, and that editors of horticultural works would give the matter their attention to the advantage of the public. "H. S." may know where to find the information; if so, he has been more fortunate than I, in which case, when I point out to him the important omission he has made, I hope he will supply my want. As I have said that I have failed to find such information in horticultural works, your readers will, I hope, excuse my going to meteorological publications, and, notwithstanding the uninviting name, let me here say that they will find the "Journal of the Scottish Meteorological Society," under the editorship of Mr. Alexander Buchan, as interesting a work on horticulture as they will meet with. Let me take the liberty of giving an extract from his paper "On the Weather Conditions which Produce Large Crops of Cereals," and they shall judge of the value of one at least.

"The weather of this period was drier in 1863, and the sunshine greater than in 1861; and the temperature of the day was about equal, but of the night about 3° lower in 1863: hence, though the temperature of the air was no warmer in 1863, but during the nights rather colder, yet the weather of that year must be regarded as more conducive to the ripening of the crops, owing to its greater dryness and to the greater sunshine, which brought the crops, as it were, into more immediate contact with the sun, so that they ripened under a higher temperature than was indicated by the thermometers placed in the shade." Again, he says,—"Thus at Sandwich, on the 26th of July, 1861, when the protected thermometers stood no higher than 55.1°, the ears of corn were ripening in a temperature of 80.2°."

Thus, I have found that no less an authority than the Secretary of a Meteorological Society is of my opinion, that for farming and horticultural purposes, mean temperatures which are founded on temperatures in the shade are only calculated to mislead in making comparisons between one year and another, and, therefore, we must follow the same rule in making a comparison between the French climate at the 45th degree of north latitude, and the temperature we should maintain in our Vinehouses during the day. But we have lately read in another journal some papers on the power which moisture in the atmosphere has, even though invisible to us, to prevent the loss of heat through radiation, and also the interesting discussions these papers provoked. This is simply a branch of the same subject; and though some have told me it was too highly scientific for them to understand, or to think of much practical use to gardeners, let us turn to the Journal of this Meteorological Society to find some experiment that will simplify it till it comes within the range of our comprehension.

Two months since there was a sale of new Orchids advertised, part of which, it was said, were found growing at an elevation of from 12,000 to 16,000 feet on the Cordilleras of Ecuador. What this climate is I do not know, but by the theory "H. S." has given us, if it were anywhere in Europe it would be within the limits of perpetual snow, and, therefore, would have a "mean temperature" low enough to warrant any cool treatment; but in practice it will be found entirely to depend on the dryness or humidity of the atmosphere, as altitude considered apart from latitude makes no difference in the power of the sun's rays, as those who have toiled up a Swiss mountain under a burning sun can have no difficulty in testifying. About 10,000 feet has been the most lengthened of my experiences, and on that day I was made aware that what Mr. Alexander Buchan speaks of as the extra power of the sun in dry and sunny weather was not theory; but I will give the figures that it may be seen what sort of a climate such an Orchid would require had it been found upon the Pic-du-Midi, which is a mountain just upon the 43rd degree of north latitude, and having an elevation of 9439 feet. The comparison is made with Bagnères, a town situated at its foot, the elevation of which is 1808 feet. The first result given is an average of twenty-two observations taken simultaneously at the two places between 7 A.M. and 2 P.M., "in a clear sky, full sun, and calm air." At Bagnères, air in the shade, 72.1°; soil on the surface in the full sun, 97°. On the Pic-du-Midi, air in the shade, 50.2°; soil on the surface in full sun, 92.8°. The second result is the absolute maximum in the sun and the corresponding in the shade. At Bagnères, in the shade, 80.8°; in sun, 122.5°, on the 9th of September, at 2 P.M. On the Pic-du-Midi, in shade, 55.8°; in sun, 126.1°, at 11.30 on September the 10th. To show the rapid manner in which the soil is heated, at 7 A.M. it was only 48.7°, and at 11.30, 118°, on one occasion upon the Pic-du-Midi. The lowest minimum was, at Bagnères, air 58.8°, soil 57°; on the Pic-du-Midi, 34.3°, soil 32.2°—both taken upon the night of September 9th. Such are the vicissitudes of the temperatures of the air and soil during twenty-four hours upon a mountain in the 43rd degree of north latitude, 9439 feet high. What they are at an elevation of from 12,000 to 16,000 feet under the line of the equator I do not know. My intention is not to injure the sale of these Orchids, or to discourage their cultivation, but to point out, as these experiments undoubtedly do, that the power of the sun's rays cannot be judged by "mean temperatures in the shade," any more than the mean night temperature will show how much heat the soil has lost by radiation, as they both depend on the moisture the atmosphere holds in suspension. There are few counties in England that cannot show within the distance of twenty miles two distinct climates caused by one being "much drier and, therefore, sunnier than the other."

"H. S.," from what he says, has lived longer in France than I have, my visits having been limited by the time I could spare from business; but as these visits have been at most periods of the year, I have been able to observe that the spring season in France is not as much earlier in proportion as the summer, and that therefore the reason of the period of maturity of their harvests having gained upon ours at a much greater rate than the difference of the mean temperatures would indicate, is that it is "drier and sunnier," but of the value in figures of this advantage I am ignorant, as I have not found any French meteorological table containing, as those of our two societies do, a column for heat in the sun, and I am this important point short before I can know all the advantages of the climate of Toulouse. M. Ch. Martins's paper supplies me with one item—that on the 9th of September, by the way not the hottest month either, at Bagnères 80.8° in the shade gave 122.5° in the sun, and that town is only six-tenths of a degree south of Toulouse. In June, in London, I have before shown 80° in the shade can give 130° in the sun. If "H. S."

really wants to make a comparison between the day temperatures in a vinery he should give us the mean of all the maxima in the shade, which means the mean of the day temperatures. The mean of all the minima, which means the mean of all the night temperatures, is as interesting but for reasons I am not now considering; but the "mean temperature," which is the mean of these two, is of no value whatever.

"H. S." asks Mr. Thomson the question that if he begins with 100° in the sun for Vines, how he will go on if he is asked to advise temperatures for semi-tropical and tropical plants? I find in the Journal of the French Meteorological Society, some readings taken in Algeria, which I will give. I am sorry that they do not go any further than June 21st. I have taken the forty-eight hours included in the 18th and 19th of June.

June.	Locality.	A.M.	P.M.	Temperature Cent.
18th	Gueltestel	4.30	..	21.5
"	....	5.0	..	24.5
"	Ain Oussera.....	10.55	..	34.5
"	....	12.0	..	35.5
"	....	..	2.0	37.0
"	....	..	4.0	36.0
"	....	..	5.0	34.7
"	....	..	7.15	31.4
19th	....	4.0	..	18.0
"	Boughezoul.....	9	..	30.7
"	....	10.30	..	32.9
"	....	11.30	..	35.8
"	....	..	2.20	37.8
"	....	..	3.30	36.3

If my calculation is correct, 18°, the lowest here given, is equal to 64.60° of Fahrenheit; and 37.8°, the highest, is equal to 100.5°. As, therefore, the Date Palm will not grow north of the Mediterranean, it requires a summer temperature of not less than 65° at night, and 100° in the shade during the day, which, without wishing to anticipate Mr. Thomson's answer, is quite enough for the first step.

M. Ch. Martins, who is the author of this paper giving the results of the experiments he made upon the Pic-du-Midi, says, in his concluding remarks, M. Ramond found on the Faulhourn, which is 8803 feet high, and at its top has only a superficies of 3¾ acres, 131 flowering plants, whereas M. Malingren could only find ninety-three in the whole of the Spitzbergen archipelago. The following is his explanation:—"Independently of their original geographical distribution, the temperature explains to us the number and variety of the species which grow on the summits of the Alps and Pyrenees, because there they are warmed by the soil into which they strike their roots, more than by the air with which their leaves and branches are enveloped, and because the clear lively light prevailing in these high situations is favourable to the functions of respiration; whilst at Spitzbergen, on the other hand, in spite of the continual presence of the sun above the horizon during summer, the heat of the sun's rays, being almost totally absorbed by the great thickness of the atmosphere they traverse, is incapable of raising the temperature of the soil above that of the air." From this, which is the strongest argument I ever read in favour of what we gardeners call bottom heat, to grow Alpine plants and Orchids that have been collected from these high elevations, we must depend more upon soil heat than atmospheric heat for their successful cultivation.

Now for my conclusion. Any one who will read with intelligence all the information I have here gathered, bearing upon the necessity of taking advantage of all these great helps the sun will give us if we let him, and who will then consider how we turn them to advantage in building such lean-to vineries as Mr. Wills has described, where the foliage is trained so as to keep out as much of this valuable source of light and heat will, I think, agree with me that he would not build a lean-to for any purpose whatever.

I noted a few weeks since that the author of "Cordon Training" agreed with what I wrote you last year, that the successful orchard-house must be a lean-to—that is, in his meaning, it must have the advantage of the radiation of the back wall, which is right, so far as it goes; but, why not have as much of this advantage at the top of the wall as the bottom? The only answer is, That by so doing the wind would play upon it, and you would lose heat; but a sheet, such as a simple wall is often supplied with, will stop all this, and if let down at night will prevent the frightful loss of heat by radiation. How many gardeners have seen their crop eaten up by red spider, and the leaves burnt by what they say is the fault of their not being able to keep up moisture enough in the day, notwithstanding all their damping down; but they never think that on clear nights as much damping down is required, though the house receives none. Semi-lean-to houses have an undoubted popularity, and in the hands of most gardeners will, I believe, prove the best, the reason is on account of their negative qualities. I shall prefer the positive advantages, and when I build make large square houses, and by growing the Vines or Peach trees on trellises, enable the sun to pervade the whole house and warm the border in addition.—G. H.

ROSES AND FRUITS AT OKEFORD FITZPAINE.

I HAVE read "D.'s" account of things here. It is tolerably correct, but not quite so. "Everything" in the shape of Roses is *not* cut down to the ground. There are some hundreds of fine plants, from 3 to 4 feet high, in fine health, foliage, and buds. I never had them better. There are some hundreds cut down by the frost, and some hundreds I was obliged to cut down; for, though their skins were perfectly green, their pith was the colour of areca nut. Hence, they broke at their base instead of their summits, which was so unnatural that I was led to examine into the cause, and I found that the frost had injured the pith and wood without defacing the skins. As good wood cannot come out of bad wood, I cut them down; and they, as well as the preceding, are breaking grandly. I have Roses showing colour, and expect a bloom of Maurice Bernardin next week, and to commence generally in about three weeks, or a month, with the unmutilated division. I usually obtain from my Manetti plants three series of flowers—namely, in May and June, in July and August, and in September and October. Briar Roses will rarely give more than two series.

As regards hardiness and endurance, much depends on the nature of the Rose, and also on its health and position in the garden, and still more so on the dryness or wetness of the place. My experience does not agree with that of others as to Roses said to be tender, half hardy, and hardy. In such a winter as the last all required protection, and Teas and Tea-scented Noisettes extra protection. I have lost up to this time twenty-five out of 1200 (one hundred being nothing better than pot plants), and, perhaps, a dozen more may yet go wrong; but all the others are in beautiful condition. It is people's own faults losing so many Roses. They are possessors of Roses rather than rosarians. I do not know six men in this kingdom worthy of the name. I mean hard-working, painstaking rosarians, who try to keep their Roses out of mischief, and know how to extricate them when they get into it. What a pity! for what other class of plants will begin on south walls in May and continue in the open ground in never-ceasing blooming till frost stops them? A rosarian has no business with other flowers. From one to two thousand Roses demand exclusive attention. I have no other flowers here except a few Violets, and a dozen of Stella Pelargoniums. I do not wish to see other flowers superseded, but I wish professed rosarians would work harder to deserve the name, instead of abusing the Roses and the nurserymen who supply them.

I am happy to tell "D.," that my splendid array of Tea-scented Roses are breaking grandly. I think they will be themselves again. I am surprised that anything survived. There are a few bud worms here, but very few aphides, and these are mainly on wall fruit trees, which are syringed every day to preserve their beautiful foliage, which in most gardens is blistered or devoured. Without water we cannot successfully "garden," and without a "will" to use it, the water is of no use.

The Strawberries are in superb bloom. The maiden cordons have set some of their fruit. Bellegarde, Noblesse, Prince of Wales Peaches, and Prince of Wales Nectarine, which are growing nicely. Twenty-eight out of 107 maiden cordons bloomed well, but owing to the violent west wind pushing one of my walls (9 inches thick) out of the perpendicular, I had to take up this spring forty-one of the maiden cordons, and put them in the centre of my garden till the wall was rebuilt. This, of course, stopped them from perfecting their blossoms. Mr. Rivers and Mr. Bréhaut gave me no hope from maiden cordons, but I fancy I shall have some fruit from some of them. The cordons were deprived of their branches, and the fruit is on the main stem. I am trying experiments with them, and if I strike out a spark, I will make it public. None but the rash ever do strike out a new spark.

I am sorry to say that my Plum trees are suffering from

mildew (white) on the under side of the leaves. I hope it is not general. I shall syringe them with vitriol and water, which is my remedy for fungoid diseases. Moreover, it is a capital "tickler" for aphides and red spiders.

It is too early to speak of the Apple crop. I do not think it will be so good as last year. Pears on the Quince stock are a nice crop, but deficient on the Pear stock. Gooseberries and Currants are abundant. I allow seven ducks and two drakes to traverse my gardens. They are the best destroyers of slugs and worms, which attract the blackbirds and thrushes.—W. F. Radclyffe, *Okeford Fitzpaine.*

ROYAL HORTICULTURAL SOCIETY.

Weekly Show, *May 18th.*—Prizes on this occasion were offered for collections of Pelargoniums (Amateurs); Azaleas (Amateurs); miscellaneous plants; cut flowers, arranged in a basket (Open); and for the best exhibition of fruit. In Pelargoniums, Mr. W. Bartlett, Shaftesbury Road, Hammersmith, obtained the first prize; and Mr. A. Wilkie, gardener, Oak Lodge, Addison Road, Kensington, the second. Mr. Wilkie was awarded the first prize for Azaleas. For collection of plants, miscellaneous, Mr. A. Wilkie obtained the first, and Mr. W. Bartlett the second prize. Mr. Morgan, Ball's Park, Hertford, gained the first prize for a collection of cut flowers; Mr. A. Wilkie was second, and Mr. W. Bartlett, third. An extra prize was also awarded Mr. Morgan for a dish of very fine Keens' Seedling Strawberries. Mr. A. Wilkie obtained an extra prize for a miscellaneous collection of plants; also Mr. W. Bartlett for the same. Mr. Morgan exhibited a collection of cut Roses, which, added to a fine collection of Roses in pots from Chiswick, made a very pretty exhibition.

Special Floral Fete, *May 20th.*—It having been announced that Her Majesty would pass through the gardens of the Society after the ceremony of laying the first stone of the Royal Albert Hall of Arts and Sciences, it was determined to hold a special fête on the occasion, and to this several of the leading nurserymen contributed liberally. At the east end of the conservatory Messrs. E. G. Henderson, of Wellington Road, had a small but charming group of Ferns, Tricolor Pelargoniums, &c., edged with a double row of the pretty Silver-leaved Meadow Grass and a triple row of Pyrethrum Golden Feather. Messrs. Veitch exhibited the next group, consisting of Palms, Dracænas, Marantas, Bertolonias, Coleus Veitchii, and other fine-foliaged plants, of which the bold yellow-variegated Sanchezia nobilis variegata was conspicuous as one of the newest and finest. Of flowering plants Messrs. Veitch had fine Saccolabiums, Aërides, Lælia purpurata, and other Orchids, a fine specimen of the brilliant-coloured Anthurium Scherzerianum, Lilium auratum, Amaryllids, Pimeleas, several fine Azaleas, &c. Messrs. Lane & Son, Berkhampstead, had groups of small Rhododendrons and Azaleas in excellent bloom and tastefully arranged; and Mr. Turner, Slough, a large group of Pelargoniums, Calceolarias, Hydrangeas, Heaths, and other flowering plants, along with Alocasias, Marantas, Dracænas, and Ferns, the whole ascending from an edging of Isolepis and Ferns to a wreath of Bougainvillæa at the back. Messrs. Low & Co., Clapton, furnished a similar collection of Cattleya citrina to that which they exhibited on the 7th, but more numerous, comprising no less than 105 specimens, and of many varieties. From Messrs. Lee, Hammersmith, came specimens of Azaleas, Aphelexis, Erica Cavendishii, Cordyline indivisa, Ferns, and other plants with ornamental foliage; and from Mr. Bull a group consisting of Palms, Dracænas, and other fine-foliaged plants, including several of those exhibited a fortnight ago, such as the silvery-veined Fittonia argyroneura, Eranthemum igneum, Echites rubro-venosa, Dichorisandras, Bignonia ornata, &c.; whilst of flowering plants Mr. Bull had Lilium auratum, Cypripediums, and Phalænopsis grandiflora intertwined with Bougainvillæa spectabilis, of which there were also several wreath-like shoots.

In the north-western conservatory arcade Messrs. Bull, F. & A. Smith, Watson, Carter & Co., E. G. Henderson, Downie & Laird, Williams, and Perkins, exhibited fine collections of Tricolor Pelargoniums. Messrs. E. G. Henderson, in addition, to their remarkably fine display of Tricolor Pelargoniums, sent a variety of ornamental-foliaged plants; Mr. Williams sent a similar collection along with some flowering specimens; Messrs. F. & A. Smith, Heaths; Messrs. Ivery, British Ferns. Mr. William Paul contributed one of the most beautiful collections of variegated shrubs we have ever seen, along with a magnificent specimen of the variegated Hydrangea in bloom, and to the beauty of which description would fail to do justice; likewise some beautifully variegated Ivies, Aucubas, Beaton's and other Pelargoniums, as well as several boxes of fine cut blooms of Roses. Mr. Turner, of Slough, sent a stand of Tulip blooms, likewise Pelargoniums, Calceolarias, &c.; Mr. Cunningham, The Forge, Burton-on-Trent, his pretty variegated Ivy-leaved Pelargonium L'Elegante; and Messrs. Paul & Son stands of cut Roses.

Her Majesty, on leaving the site of the new Hall, passed into the conservatory of the Royal Horticultural Society, and through the north-western arcade, and after pausing for a short time to examine the floral display, left the gardens, in which were assembled several thousands of the Fellows and their friends. The Orchids in the bouquet presented to Her Majesty on the occasion, were supplied by Sigismund Rucker, Esq.

Floral Committee and Exhibition of Tricolor Pelargoniums, *May 21st.*—The subjects exhibited on this occasion were so numerous, and the Committee were engaged till so late an hour before their decisions were completed, that we must defer a detailed report till next week, when we shall be able to give a complete list of the certificates awarded. Of the many beautiful collections of Tricolor Pelargoniums exhibited, it is scarcely possible to speak too highly. The varieties of which they were composed were almost innumerable, still the number of those showing a well-marked difference from others was not so great as might be supposed. Messrs. E. G. Henderson contributed several beautiful collections. One comprised fine specimens of Lucy Grieve, with a very bright zone; Sophia Casack, Lady Cullum, Sophia Dumaresque, Sunset, and Italia Unita. Sunshine, having a yellow edge and a very showy flamed deep crimson zone, was awarded a first-class certificate; and in the same collection was Stella sulphurea marginata, the leaves broadly edged with yellow, and of course without tricolor markings. From the same firm came also a collection of miniature Tricolors, both golden and silver-edged, most of them not exceeding 4 inches in height, and consisting of Golden Pet, The Bride, Jenny Wren, The Fairy, Queen's Favourite, Little Dear, Little Pet, Minnie, Tom Tit, Little Harry, and one or two others. Several of these were very pleasing from their dwarf growth, and seemed well adapted for edgings. Messrs. Henderson also sent a number of seedlings between the Golden-bronze zone and Tricolor sections; seedlings of 1866, showing the entire green leaves of the first growth breaking into a variegated form; others which for various causes had been found defective, as well as a number of other illustrations showing the progress of varieties. Mr. Bull had also a very fine collection of new sorts raised by Mr. Wills, and having variously-coloured zones. Of these Beauty of Ribblesdale was very conspicuous. It has very large leaves, with a showy, broad, reddish bronze zone on a yellow ground. This fine variety received a first-class certificate, as did Her Majesty, a compact-growing kind of a similar character. We also noticed Beauty of Caulderdale, a bold-leaved variety of the same class; and of Tricolors Florence, Lizzie, and Unique. Mr. Wills laboured under some disadvantage in having cut for propagation some of his best varieties before the Show was determined on, but the exhibition was very creditable to his skill as a raiser. Messrs. Garaway & Co., of Bristol, had a number of good varieties, bronze-leaved and Tricolor; of the latter Mrs. Allen received a first-class certificate. It has nearly circular leaves with a narrow golden edge, and a regular crimson zone, very bright in the young foliage. From Messrs. Carter and Co. came a collection of seedlings, several of which were very remarkable in character, and it was only the circumstance of their being seedlings that prevented some notice being taken of them. One shown as No. 195 on the previous day, and afterwards named Prince of Wales, had leaves 5 inches across, with a broad yellow edge and a very broad red zone. If it maintain its character when propagated it will be a great acquisition.

Mr. Grieve had a very fine collection, the star of which was the variety called Victoria Regina. This beautifully-marked variety deservedly received a first-class certificate. Minnie Warren, with a broad white edge, was also very pretty; and Mrs. Turner, with a dark green edge, a broad bronze zone, and a light green centre, was very distinct. Messrs. F. & A. Smith had a large and fine collection, and received several certificates; and other numerous collections came from Mr. J. J. Chater, Gonville Nurseries, Cambridge; Messrs. Windebank & Kingsbury, Southampton; Maule & Son; and Saltmarsh, of Chelmsford, the latter receiving a first-class certificate for Sunrise, a compact-growing Tricolor. Mr. W. Paul, Messrs. Downie and Co., Hally, Aldred, of Kilburn; Perkins, of Coventry; Laughois, of St. Helier's; Watson, St. Albans, and others, also exhibited Tricolor varieties though less numerously.

Messrs. Veitch exhibited a fine collection of new plants of which Dichorisandra mosaica, Dracæna regina, a new Adiantum, Retinospora filifera, and Maranta illustris, received first-class certificates; and Dichorisandra undata one of the second class. Mr. Bull, who had also a good collection, received first-class certificates for Anthurium regale, Dichorisandra mosaica, and the handsome spreading Zamia villosa, and a second-class certificate for Dichorisandra undata. For a pretty Golden Elm, from Mr. W. Paul and Messrs. E. G. Henderson, a first-class certificate was awarded to both. W. W. Buller, Esq., received a special certificate for fine examples of Lælia purpurata, and several other Orchids were shown, notably a collection of Cattleya citrina, by Messrs. Low, of Clapton. Many other subjects were shown and received certificates, but we must defer noticing these till next week.

Fruit Committee.—Rev. George Kemp in the chair. Prizes were offered for the following subjects:—1, The best three dishes of dessert Apples. In this class there were three exhibitors—Mr. Lynn, gardener to Lord Boston; Mr. Whiting, of the Deepdene; and Mr. Cox, of Redleaf. Mr. Lynn and Mr. Cox each showed two collections. The first prize was awarded to Mr. Whiting for Adams' Pearmain, Mickleham Pearmain, and a variety not named, but which was similar to Federal Pearmain. Mr. Lynn was second with Scarlet Nonpareil, Golden Knob, and Cockle Pippin. Mr. Curd, gardener at Sulhampstead House, Berks, obtained a first prize for three dishes of Straw-

berries. They were fine fruit and in good condition, consisting of Reeves' Eclipse, Marguerite, and Sir Harry. For the best dish of Cherries, Mr. Lynn took a second prize with Frogmore Early; and Mr. Tegg was awarded a first prize for a splendid dish of Bellegarde Peaches, from the Duke of Newcastle's garden at Clumber. Mr. Pearson, of Chilwell, exhibited a dish of Walnuts that had been kept in fine condition by Mrs. Hetley, of Orton, near Peterborough, for two years and five months, to which a special certificate was awarded. The method adopted is to allow the nuts to fall naturally from the tree, then dry them in the sun and wind, and afterwards to hang them in bags in an attic. Mr. Cox, of Redleaf, also received a special certificate for a collection of six kitchen Apples kept in fine condition. Mr. Short, gardener to Lord Eversley, Heckfield, sent fruit of the curious Cerasus pseudo-cerasus. It is a small Cherry of a pale amber colour, with a hooked beak at the apex, and in some instances grows in pairs on one stalk, like the Cluster Cherry and Bigarreau Legrey. The flavour is flat and insipid. Mr. Shortt also specimens of young Pears, showing how much the crop this season is infested with grubs, and from this cause it may be anticipated that the Pear crop will suffer much.

General Meeting.—W. Wilson Saunders, Esq., F.R.S., in the chair. The proceedings of this meeting were of unusual interest, and the Council-room was densely crowded.

After the election of seventeen new Fellows, and the admission of the Wolverhampton Horticultural Society into union, the Rev. M. J. Berkeley remarked that as the meeting was chiefly devoted to Tricolor Pelargoniums, it would be most instructive to call attention to the principle on which their colouring depends. The original species from which they were all derived was the old Cape Pelargonium zonale, of which he produced a specimen, and of which the leaves are only slightly zoned. The first improvement on this was Fothergillii, which was not imported but a seedling, and from that improvement all the fine varieties around him had sprung. Mr. Berkeley then remarked, that variegation really is a disease; in fact, in the vegetable kingdom everything not normal in structure is a disease, giving as examples Kohl Rabi, the useful portion of which results from an obstruction in the stem; Radishes, &c. Celery when blanched was also in a diseased state, so were the fine varieties of Roses and Tulips. Mr. Berkeley then exhibited diagrams showing the structure of the leaf of one of the best brown-zoned Pelargoniums. On the upper surface was a thin layer of cuticle, next to this a layer of cells containing no colouring matter, then cells of chlorophyll, but sometimes instead of being green the cells of the zone were filled with red colouring matter, and in proportion to the number of red and green cells, so was the character of the leaf. The brown colour of the zone depended on the green colour of the subjacent cells shewing through the red and giving an olivaceous tint; and in the Tricolor varieties if the variegation was yellow, the yellow cells shining through the red produced a flame colour. Beautiful, however, as were the plants exhibited, it might safely be concluded that perfection had not yet been attained, and he held up as a model a drawing of a leaf exhibiting distinct zones of yellow, red, and green, without radiation.

The Rev. Joshua Dix congratulated the meeting on the success of the Exhibition, the idea of holding which had first originated with Major Clarke, and it was warmly taken up by the Council. The Floral Committee had had great difficulty in performing their task, owing to the great similarity of the varieties, and had, in fact, not completed their awards when the meeting commenced. He might mention, as the Committee could give no certificate to yearlings, because such could not be depended on, many exhibitors would be disappointed, who had brought most exquisite plants, with which no fault whatever could otherwise be found.

The Chairman then called upon Major Clarke.

Major R. Trevor Clarke said, that when he had put together a few notes on the general phenomena of variegation in plants, he was not aware that the subject would be taken up by Mr. Berkeley; but as his own views previous to the meeting were somewhat different, he would state them. Major Clarke then said:—"Few who have been accustomed to roam about with observant eye through copse and dell, or by lake and river, in the sweet spring time, can have failed to notice the frequent occurrence of variegation in wild trees, shrubs, and plants. Whatever the nature of it may be, it is certainly not a special effect of cultivation. What is it, then?—a morbid state, as proposed by some? I think hardly so. Although in some cases accompanied by constriction of the leaf and tenderness of constitution, these conditions are by no means necessarily concomitant. Not a few plants in the variegated state are healthy and vigorous. The beautiful gold or silver Holly sprig with its coral berries that decks our homes at Christmas tide, was gathered from a strong and healthy tree, as strong and healthy as those plainly clad in homely green. They do say the berries won't grow, but that we may have to discuss by-and-by. Again, the Sycamore, with its leaves striped with silver, or flecked and dusted with gold, is a lofty, vigorous, and healthy tree.

"Gardeners have but little to say against the general good constitution of our beautiful queen of the May, Mrs. Pollock. She is of fair and noble presence, and, like another Monarch in our land, has given birth to a fair, noble, and numerous offspring. Mrs. Pollock still lives in the hearts of our gardeners as our own dear Queen lives in the hearts of her people (applause). Say, then, is this strange and certainly beautiful manifestation a healthy but rarely occurring natural phenomenon? It is not a normal one, for there is in such plants a constant tendency to recur to another form which is more frequent than itself. Gardeners call it a sport, translating unconsciously the *lusus naturæ* of the old Latinists. It certainly appears more frequently as a bud-formation than as a seed-change. Poor Dr. Lindley used to say that a bud and a seed were pretty much the same thing; the main difference is, that in the case of reproduction by seed, like never, strictly speaking, produces like. I once made a very curious observation bearing upon this subject. A half-variegated or magpie seedling Pelargonium grew into a plant, and in this plant I traced the unmingled lines of green and white from stem to branch, from branch to flower-stalk, and thence to the seed-vessel, which enclosed a particoloured seed. That seed again produced a pied offspring, of which one cotyledon was white and the other green. When a pure green line in this case passed up into the seed-vessel the seed was green, and so was the seedling. A white stripe, or line, ruled in like manner the destiny of a pure white offspring. These latter never developed a second or true leaf pair. Seedlings with golden seed-leaves, however, produce perfect plants.

"Perhaps we should not be far wrong in considering variegation, at any rate symmetrical variegation, as an occasional natural state, and to class it with other unusual developments—as laciniations in entire-leaved plants, red or yellow twigs where plain brown should be the rule, the abnormally rampant shoot lately observed on the Devonian Tea Rose, and the pigmy Clanbrazilianised branch occasionally seen mimicking a rook's nest high on the lofty Norway Spruce tree. I will not take up your time in multiplying instances, but hope that I have sufficiently explained myself on this point.

"Closely connected with variegation, or the partial absence of chlorophyll from the leaf, is the occurrence of striped or pure white flowers upon red, blue, or otherwise coloured plants. I find that the colouring matter, if white may be called a colouring matter (and in this case it is), is identical in both cases. It is probably the fact that both in white flowers and variegated leaves there exist yellow cells, which become more apparent when the tissue is treated with an alkali. I believe the colouring matter is what chemists call luteoline. For fear of wandering into another and still more interesting subject—that of the colouring matter of flowers and plants in general, I will not now allow myself to soar into the regions of chemistry; I will merely remark that this subject has been partially investigated by several distinguished French chemists, and that I hope I may live to tell you some day what little glimpses they gained from their peep into Nature's wondrous laboratory.

"I regret extremely that circumstances have prevented me from contributing more practically, I mean in the way of plants and so on, to this most interesting Exhibition, and that for the same reason I have not been able to put together a more detailed scientific note or collection of facts on the subject. I have scarcely attempted this, my mission to-day being principally to place before you a subject upon which I understand several of my brother gardeners are prepared to give some valuable and interesting information. How well they have responded to our invitation to ventilate this subject I need not say. We reckoned upon a respectable few enthusiastic exhibitors with a few choice plants, but they have come upon us like an army, even like the Byronic Assyrian, "their banners are gleaming with purple and gold." On entering the room this morning I found Judges and Committee in a state difficult to describe, in a perfect *embarras de richesse*. It had evidently been raining Golden Pheasants and Golden Fleeces. Poor Mr. Dix stood there looking like—like—Danäe in a golden shower of Mrs. Pollocks."

Major Clarke then introduced to the Meeting Mr. Grieve, as one of the gentleman who had offered to read a paper.

Mr. Grieve, after expressing his gratification that the Tricolored class of Pelargoniums had been considered of sufficient importance to form the subject of a special exhibition, said that as his efforts had, he believed, been admitted to have been in some degree instrumental in the production of that beautiful race of ornamental plants, and as discussion and information on the subject was invited, it would not, he hoped, be considered presumptuous to offer a few remarks on their history.

The cause, or causes, of variegation in the leaves of plants, including, of course, the Pelargonium, were as yet, he believed, unknown, consequently no means could be successfully used to produce it; but when from some unknown cause it spontaneously developed itself in an individual plant, then, in accordance with the law or doctrine of hereditary transmission of qualities, little difficulty was experienced in inducing it to reproduce itself in succeeding generations. The chemical or other changes, however, which must take place in a plant to induce its foliage to become variegated, present, undoubtedly, a very interesting subject for inquiry, and were worthy, it might be supposed, of the attention of the vegetable physiologist. He had at different times consulted various authorities upon this subject without, however, being much enlightened thereby. Dr. Hope says that there is in plants a colourable principle, consisting of two separate parts, one of which forms a red compound with acids, while the other forms a yellow with alkalies; and he attributes the green colour, produced by the latter, to the mixture of the yellow matter with the blue infusion. The two principles, according to him, may exist together or separate in different parts of the same plant. Dr. Balfour also says,

"The whitish or brown spots which occur on the leaves are often produced by thickened cells, containing peculiar colouring matter, underlying the chlorophyll cells. In such cases variegation might be traced to an alteration in the epidermal cells, and the same is true of certain bright colours assumed by the surface of some leaves."

With regard to the leaf of the Tricolored Pelargonium, Mr. Grieve said he had sometimes been inclined to think that the zone undergoes no change whatever when the leaf becomes variegated, or yellow margined; and notwithstanding the fact of red being one of the primary colours, consequently, according to theory, cannot be produced by any combination of colours; but covering, as the zone does, the junction of the yellow margin with the green disc, or centre of the leaf, we find that whatever part of the zone rests upon the yellow appears bright red, while the portion which may rest upon the green part of the leaf retains its normal or brown colour. The question, then, is, How is this red colour produced? For his own part, he too hastily jumped at the conclusion that the brown and yellow had produced the red; but this, according to the theory of colour, could not have been the case. So he had to leave the settlement of this interesting question to those whose scientific knowledge would qualify them for the task.

Before proceeding to furnish what little information he could as to the history of the Tricolored Pelargoniums, he might notice a defect incidental to the Silver-tricolored section, but without being able, he was sorry to say, to suggest a remedy. He alluded to the cupping, or crumpling of the foliage, more particularly when the varieties are cultivated in the open air, and if the weather is at all cold and wet. This crumpling appeared to be caused by the fact of the white or colourless margins being unable to expand in proportion to the growth of the green or central part of the leaf, consequently cupping or crumpling was inevitable; and very possibly this deficiency of expansive power in the white margins of the leaves might be attributed to the nearly entire absence of chlorophyll or green colouring matter; and that this defect does not in any way apply to the yellow-margined varieties might be accounted for by the fact that their yellow margins are not entirely destitute of this principle.

Some twenty years ago there were, he believed, but few varieties of variegated Pelargoniums in existence. Of these, the two best fitted for the purpose of bedding or massing in the flower garden, were a sort known as Variegated Nosegay, and another called Mangles's Variegated Nosegay. Of the origin of the first-named he knew nothing; of the latter he had heard that it was obtained by the late Captain Mangles as a sport from a green-leaved variety. This sport is well adapted for the purpose of bedding, and still, he believed, extensively used in that way. The two varieties named above were both silver-margined sorts, with nosegay or very narrow-petalled flowers. The only golden-margined sort of any merit at that time was the variety known as Golden Chain, and of its origin he was also quite ignorant; but he had been informed by an old gardener that he recollected having grown it along with a collection of stove plants nearly fifty years ago. About seventeen or eighteen years since the horticultural world was somewhat startled by the announcement of a scarlet Pelargonium, having broad-petalled flowers and variegated foliage. This proved to be the celebrated and now well-known variety called Flower of the Day, and he believed that it was to Mr. Kinghorn that we were indebted for the introduction of this forerunner of a highly ornamental race of plants. This variety was soon followed by others of increased merit, the production of more than one successful raiser, among which the names of Lennox, Elphinstone, &c., deserved to be mentioned. Amongst these new introductions the beauty of several varieties was greatly enhanced by having, in addition to their silver margins, a red or pink zone, well defined and exceedingly beautiful when the leaves were in the early stages of their development. These varieties, combining as they certainly did, three distinct colours in their foliage, might with propriety be designated as the forerunners of the Silver-tricolored race, and to Mr. Kinghorn he believed belonged the credit of having originated the first of them, named, he thought Attraction.

About the year 1855 or 1856, he (Mr. Grieve) had succeeded in originating several varieties which were considered as advances on their predecessors, the best of which, however, was the variety named Italia Unita, which in its class is, perhaps, unsurpassed; and about the time stated above it occurred to him that similar improvement might possibly be effected in the golden-margined varieties, which at that time consisted of only Golden Chain and one or two other sorts inferior to the sort named. But at all events he confined his experiments to Golden Chain, and after trying many experiments, many of them resulting in failures, he at last succeeded in originating two varieties which were considered as worthy of being distributed under the names of Golden Tom Thumb and Golden Cerise Unique. These were succeeded by Gold Pheasant, which was also in its turn eclipsed by the variety known by the name of Sunset, and in the following year he succeeded in raising the now well-known variety Mrs. Pollock, which was succeeded by Mrs. Benyon, Lucy Grieve, and lastly, Lady Cullum, now being distributed by the Messrs. Henderson, and about which variety it was quite unnecessary to say that it would be sure to prove a public favourite. The great desideratum in a variegated Pelargonium, said Mr. Grieve, is a vigorous constitution, and, consequently the power of rapid increase by cuttings; and this quality is possessed in an eminent degree by the variety referred to, and in a still greater degree by that which he had named Queen Victoria, and which he considered to be in all respects the best he had ever raised. On that account he took the liberty of giving to it the name of Her Gracious Majesty; but since doing so he had found that he had been forestalled, as the name had been already assigned to another variety, but he would still adhere to the name in the slightly altered form of Victoria Regina.

Soon after the introduction of Mrs. Pollock, the attention of other cross-breeders appeared to have been directed to this subject, and the consequence was, that the name of Tricolored Pelargoniums might now be said to be Legion, and growers had ample opportunities of selecting and adding to their collections varieties of the greatest merit, including, of course, habit of growth, quality of bloom, &c. In the gardening journals he had recently given the pedigree of Mrs. Pollock, so that it would be unnecessary to repeat it, but he might briefly state that the Golden-tricolor Pelargoniums which he had originated had all descended from the well-known Golden Chain.

He had also at various times tried experiments with Mangles's Variegated Nosegay, without having been very successful. It was a sort which did not produce pollen freely, nor did it seed freely when fertilised by the pollen of other varieties, and even when it does appear to ripen seeds they very frequently refuse to grow. He had, however, succeeded in raising a few seedlings from it, and one of them was known as Stella Variegata, and was produced between a seedling Nosegay variety (raised from a very strong growing sort known as Mrs. Vernon), and Mangles's Variegated Nosegay. This variety (Stella Variegata), greatly resembled sports which had at different times, and in various localities, been obtained from Beaton's Stella, although their origin as he had endeavoured to show, was entirely distinct, and their flowers of a different shade of colour. Last year, Mr. Grieve remarked, he had fertilised blooms of a small-leaved seedling Nosegay sort with well-defined zones, and which has been named Blackbird, with pollen taken from Stella Variegata, and one of the results is the Minimum variety with very white leaf margins, named Minnie Warren.

Some years since, on the introduction of some of the better sorts of the white-flowered Zonal varieties—such as Madame Vaucher, White Tom Thumb, &c., all the kinds having well-defined zones, it occurred to him that if sorts with foliage similar to Mrs. Pollock, Lucy Grieve, &c., could be induced to produce pure white flowers, it would be a very desirable acquisition, and he immediately set about experimenting in the matter, but found the process to be much slower than he had at first calculated upon. It would be tedious to describe all his experiments and failures, but in four generations he succeeded in producing plants having golden-tricolored foliage, and also producing pure white flowers, unfortunately, however, accompanied by an exceedingly feeble constitution, and apparently a strong determination to leave this world as soon as they conveniently could, and which most of them succeeded in doing. Still he managed to persuade a few of them to live; and one of them before the meeting was named The Ghost, as it was only the ghost of what he wished it to be. But the first two points had been gained—viz., tricolored foliage and white flowers, and the third point only was wanting—namely, vigour of constitution; the first step towards that point was, he believed, successfully taken, the proof of which was the variety named Eva Fish.

Two principles, it would be observed, had been active in tending to enfeeble or debilitate the constitutions of the white-flowered and Golden-Tricolor race; these were variegation itself, which always tends to diminish the vigour of any variety, and also what is called the "in and-in" system of breeding, which is known to have a similar effect in the vegetable as well as in the animal kingdom; and the method he had adopted to throw fresh blood, as it were, into the race was as follows, and, as far as he could judge, he thought it likely to prove successful:—He selected one or two strong-growing silver-margined seedlings having very light pink or nearly white flowers. These he fertilised with pollen taken from Madame Vaucher, White Tom Thumb, and some other green-leaved, white-flowering sorts. Most of the progeny proved green-leaved, a few, however, showed variegation, but he selected a few of those which showed no symptoms of variegation whatever, and when they bloomed they nearly all proved to have white flowers, and these he fertilised with pollen taken from the variety named The Ghost. The results of this cross were the plant named Eva Fish, and one or two other promising seedlings, which he had little doubt would produce white flowers.

It would appear, continued Mr. Grieve, that because the hand of science has not directed such experiments as he had endeavoured to record above, scientific men hardly feel inclined to assign to the rough-and-ready cross-breeder the amount of credit which he may possibly consider as due to his exertions. Professor Morren, in treating upon this subject, says that the cause that operates in the production of such varieties as Mrs. Pollock, Sunset, &c., is a multiple or complex one, and draws attention to the apparent diversity of the origin of such plants, and to the simultaneous appearance of similar forms in different localities in England, in France, and in Belgium. Now, all this Mr. Grieve said he believed to be incorrect, and an instance of conclusions being arrived at without trouble having previously been taken to ascertain facts. He believed, in common with most growers and raisers of these plants, that no Golden-tricolored Pelargonium deserving of the name existed antecedent to Mrs. Pollock and Sunset, and if any similar varieties originated simultaneously either in this country or on the continent, where were they to be found? or what had become of them? M. Morren further said, "These varieties

are not the result more or less directly of man's agency, nor of this or that operation of the cultivator, but they are the indirect but inevitable natural and spontaneous consequences of the mode of development belonging to the species when grown under artificial circumstances, &c." Possibly we may be told some day that St. Paul's Cathedral was a spontaneous production, independent of man's agency, &c., and some, perhaps, might be found to believe it. For his own part he believed that the Pelargonium is grown at present under much the same artificial circumstances as it was grown a hundred, or possibly two hundred years ago; and our great grandfathers might have enjoyed the luxury of bedding-out Tricolored Pelargoniums in the summer of 1767 in every way the same as their descendants were doing at the present time, had their tastes led them in that direction, and if the idea had occurred to them to use the means at their command. As he had said before, he believed that the cause of variegation was unknown, and consequently could not be produced, and the cross-breeder does not for a moment presume to say that he can control Nature. All that he can do is to watch her closely, and when he perceives her in the least degree inclined to tread the path he wishes her to pursue, he can, as it were, smooth that path, and render it as inviting as possible. He may perhaps even go a little further, and, policeman-like, touch her gently on the shoulder, and respectfully request her to move on. More than this he cannot do, for what the poet has said with regard to Nature's fairest production will also apply to Nature herself:—

"For if she will, she will, you may depend on 't;
And if she won't, she won't, so there 's an end on 't."

Mr. Grieve said in conclusion, that although the pedigree of the Pelargonium Mrs. Pollock had been made public, he would again briefly state it. The seed parent of Mrs. Pollock was Emperor of the French, and the pollen parent Gold Pheasant. The seed parent of Gold Pheasant was also Emperor of the French, and the pollen parent Golden Tom Thumb. The seed parent of Golden Tom Thumb was Cottage Maid, and the pollen parent Golden Chain. As to the parentage of some of his seedlings of the present and last years, He was unable to give any information, as in most instances both parents were themselves seedlings, and many of them had not been preserved.

The Chairman having thanked Mr. Grieve in the name of the Meeting, Mr. Wills gave some illustrations of the manner in which sports of variegated Pelargoniums become fixed, and said that although he intended to have read a paper on the origin of variegated Pelargoniums, as Mr. Grieve had touched on many of the same points he would not occupy time by reading it, but he would communicate it to the Society. Mr. Chater then stated at some length his views as to the causes of coloration in Pelargonium leaves, and differed from Mr. Berkeley in considering that variegation is not a disease.

Mr. Bateman next made some observations on the Orchids. He had heard it often remarked that these occupy too much attention at the Tuesday meetings; but his friends, Mr. Dix and Major Clarke, had on this occasion had a magnificent revenge, for he was quite overwhelmed by a golden shower. Directing attention to Cattleya citrina, of which Messrs. Low exhibited a large collection, he said that the tendency of the plant is always to grow downwards, and pointed out the singularity of the pseudo-bulbs, which are as if wrapped up in silver paper. The plant lasts a long time in flower, and he never saw a more remarkable sight than a regiment of it, nearly a thousand strong, at Messrs. Low's. It was an Orchid succeeding with very cool culture, and would do in a warm greenhouse. Cypripedium candatum, from Mr. Bull, with tail-like appendages nearly 2 feet long, next occupied attention; but all Cypripediums, he thought, must yield in beauty to C. lævigatum, which was also exhibited. Dendrobium MacCarthiæ was also shown for the third time; it was now arriving at its full maturity, and Mr. Wentworth Buller had informed him he had seen specimens of it with as many as twelve spikes of flowers, and very few Dendrobiums, indeed Orchids, would be able to compete with it. Mr. Bateman said he had next to notice a little gem—namely, Oncidium nubigenum, so called from its living almost in the clouds, for it was found in Ecuador, at an altitude of 12-14,000 feet—a greater elevation than ever attained by any cool Orchid. It had gone under the names of O. Dennisonianum and O. Phalænopsis; but Reichenbach had proved that the plants to which these names had been applied were nothing but the O. nubigenum of Lindley, for which O. cucullatum had been mistaken. The beautiful group of Lælia purpurata, and the wreaths of Bougainvillæa spectabilis, shown by Mr. Bull, were then noticed, and with reference to the latter, it was remarked that beautiful as they were, they were nothing in comparison to the plant as grown at Cliveden.

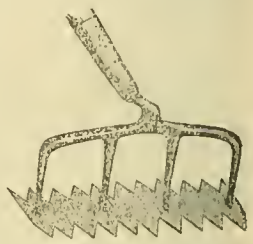
Mr. Bateman then announced that Mr. Anderson, of Meadow Bank, near Glasgow, was the successful competitor for the prize offered for the best list of Orchids arranged according to climate (see page 344), and that Mr. Wentworth Buller was second. After mentioning a Sarcopodium which was said to exist in New Guinea as a plant which it would be desirable to introduce on account of the size of its flowers, which are said to be 8 inches in diameter, attention was next directed to the Japan Flax, sold by Mr. Alison, and which whilst resembling bass matting is much stronger. Mr. Bateman considered it much superior to matting for tying purposes, and it might also be employed as a textile fibre, as exemplified by handkerchiefs made of it. Mr. Bateman concluded by announcing that the subscription to erect a memorial to the late Mr. Skinner had produced a considerable sum, which would be stated at the next meeting, by which time the subscription list would be closed.

Major Clarke said that Mr. Bateman had no right to complain that Orchids had been treated coolly, for he was always advocating that very treatment (laughter).

Mr. Wilson Saunders said that the use of the term Tricolor Pelargoniums was botanically incorrect, and exhibited a plant of Pelargonium tricolor to which alone the name should apply. Versicolor or parti-coloured Pelargoniums would be a better name; indeed the best of the so-called Tricolors exhibited not three but four colours.

SCUFFLE-HOE.

Mr. George P. Allen, of Woodbury, Connecticut, is the inventor and patentee of this little implement. It is a scuffle-hoe, consisting of a thin steel blade, with two cutting edges, which consist of a series of acute teeth, sharpened from the under side. Held naturally, by a man standing erect, the blade lies perfectly flat upon the ground, and raising or lowering the handle gives it a tendency to enter, if shoved or drawn. The common straight-bladed scuffle-hoe, though sharp, often meets with considerable resistance from roots of grass and weeds, and frequently slips over them; even hard lumps of soil obstruct its movement. This hoe readily passes through the clods, and cuts any kind of roots with ease. It is especially adapted to hoeing among garden vegetables, Carrots, Onions, and roots in the field.—(*American Agriculturist.*)



PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Dalechampia Roezliana (Roezl's Dalechampia).—*Nat. ord.*, Euphorbiaceæ. *Linn.*, Monœcia Polyandria. Native of Vera Cruz. Introduced by M. Van Houtte, of Ghent. A superb shrub above 3 feet high, involucral bracts brilliant rose colour. Flowers yellow.—(*Bot. Mag.*, *t.* 5640.)

Agave schidigera (Splintered-leaved American Aloe).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. Introduced from Mexico by M. Van Houtte, of Ghent. Remarkable for the broad white filaments given off from the margins of the leaves. Flower scape about 6 feet high. Flowers yellow.—(*Ibid.*, *t.* 5641.)

Gomphia Theophrasta (Theophrasta-like Gomphia).—*Nat. ord.*, Ochnaceæ. *Linn.*, Decandria Monogynia. Native of South America, probably the low-lying districts of Brazil. Flowers yellow.—(*Ibid.*, *t.* 5642.)

Epidendrum eburneum (Ivory-flowered Epidendrum).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Diandria. Native of swamps near Panama. Its stem having bright green leaves contrasts well with the ivory white flowers.—(*Ibid.*, *t.* 5643.)

Myrtus Cheken (Chequen of Chili).—*Nat. ord.*, Myrtaceæ. *Linn.*, Polyandria Monogynia. Flowers white. "This is one of those pretty evergreen Chilian plants, so suitable for walls in all the milder parts of England, and for greenhouse decoration everywhere, but which is apt to be cut by a winter's cold below the average, and burnt by a long summer's drought, on the eastern side of the kingdom."—(*Ibid.*, *t.* 5644.)

Fittonia argyroneura (Silvery-nerved Fittonia).—*Nat. ord.*, Acanthaceæ. *Linn.*, Diandria Monogynia. A most beautiful plant; leaves dark green; veins white.—(*Flore de Serres*, 1664.)

Hydrangea paniculata *var.* grandiflora (Large-flowered Panicled Hydrangea).—*Nat. ord.*, Saxifragaceæ. *Linn.*, Decandria Digynia. Introduced from Japan. Flowers snow white.—(*Ibid.*, 1665.)

Griffinia hyacinthina maxima (Largest violet-coloured Griffinia).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. Segments of corolla white, blue margins.—(*Ibid.*, 1667.)

Sedum maximum versicolor (Various-coloured Largest Sedum).—*Nat. ord.*, Crassulaceæ. *Linn.*, Decandria Pentagynia. Leaves green, variously marbled with yellow and pink, with an edging of the last-named colour.—(*Ibid.*, 1669.)

Gesnera.—Varieties, *Chromatella*, yellow; *Cymosa*, white and pink; *Lindleyana*, yellow and pink; *Rosea punctatissima*, yellow and spotted with pink.—(*Ibid.*, 1671.)

Zea Japonica foliis albo-vittatis (Japan Maize with white-striped leaves).—The leaves are both striped and spotted with white.—(*Ibid.*, 1673.)

Maranta roseo-picta (Rose-variegated Maranta). — Leaves with a rose-colonred band round each a short space from their edge, and pink-nerved; under surface purplish red.—(*Ibid.*, 1675.)

Pear Princess of Wales. — See Journal of Horticulture, vol. xii., page 88, n.s.—(*Florist and Pomologist.*)

CAMELLIA CULTURE.

Mr. W. Paul is nnder quite a wrong impression if he thinks it was with an eye to bnsiness I criticised his remarks on Camellias. They are no speciality of mine. One house is all I devote to their culture, and this for the sake of blooms more than with any other object. Those who have read my papers will hardly think interested motives have dictated their composition, the greater number of them being on subjects of no pecuniary interest to me. I question if Mr. Paul is older than I am, and must say I hope he does not intend to convey the impression that when he waa a boy he graw Camellias in green turf and found it fail, or that it was the old and general mode of culture. It is all very well to talk of not "depreciating the honest efforts of any fellow-labourer, however humble," but when a man takes the stand of a teacher on any subject, I think he should be prepared not only to find others differ from him in opinion, but to be asked questiona and have to reply to them. Few are in the position to speak *ex cathedrâ* on any subject, and it is better to answer with cogent arguments than ungenerous insinuations. "Dark Laurel-like bushes are not what the public want, particularly if large enough to hide a bullock." Perhaps not; at any rate the public seldom obtain them. I once sent to the gardener at Wollaton for a few blooms of white Camellias for a ladies' party, and he sent me a large clothea-basket full, "the dark Laurel-like bushes" being then almost covered with blooms.

I certainly am disappointed in Mr. Paul. I thought I ran a good risk of having my objections answered in a way which would make me appear quite in the wrong, and that I should have had to solace myself with the fact that at any rate the public were the gainers. I took up my pen

> "With the stern joy which warriors feel
> In foemen worthy of their steel,"

and instead of being set right and having explained to me what "loamy peat" is, I am told, or rather the public is, that Mr. Paul haa some thousands of Camelliaa to sell, grown according to his rulea, and that the first prize for Camellias was awarded to him by the Royal Horticultural Society. He does not say if these thousands of Camellias were propagated and grown by himself or by his foreign pupils, only that they have been grown according to his rules.

Though I have been a member of the Royal Horticultural Society some years, I never heard of the Camellia Show. I did hear of a few middling cut flowers being exhibited, which took a prize for want of competition. Surely these are not the kind of prizes of which a mao like Mr. Paul ought to ha proud. If I had grown such Roses in pota as he has exhibited, I should consider myself an authority in Rose-growing, and should he ashamed to talk of a few cut blooms of Camellias.—J. R. Pearson.

Birmingham Rose Show.—On reference to our advertising columns it will be seen that the sixth annual Show will be held in the Town Hall, Birmingham, on Thursday and Friday, July 4th and 5th. The prize list will be ready for circulation in a few days, having undergone a very careful revision at the hands of the Committee. Several features of interest have been added, of which we may particularise a class for eighteen varieties of Tea-scented, Noisette, and China Roses; another for twelve varieties of Summer Roses, including Provence Roses, (not Moss), Gallica, Hybrid China, Hybrid Bourbon, Alba, and Damask Roses; a class for amateurs who have not previously won a prize for Roses; and some useful modificationa with regard to Moss Roses. Hitherto there has been but one class for baskets of Roses, and for designs. These are now separated. Seedling Roses, new plants, seedling plants, and novel and effective methods of exhibiting cut Roses are invited, and certificates of merit will be given where deserved.

NOTES AND GLEANINGS.

It is true, though not generally known, that many of our most grateful perfumes are now produced artificially, and, what will strike most of our readers as approaching the incredible, these artificial perfumes are obtained by the chemist's art from some of the most offensive of organic remains. We believe that even the most valuable of vegetable perfumes, attar of Roses, will be eventually prepared artificially, for it is really only olefiant gas rendered solid at common temperatures. This is apparent if we place the tables of their chemical composition side by side.

	Attar of Roses.	Olefiant Gas.
Carbon	86.743	85.71
Hydrogen	14.889	14.29

Olefiant gas is the most valuable constitnent of the coal gas which illnmines our streets and houses. When pnre it is nearly scentless, but if mixed with a little chlorine gas it becomes a heavy oil, and acquires a sweet ethereal odour. Some other addition one of these days will impart to it the odour of the Rose. We were led to these thoughts by the following note on the extraction in Turkey of the attar from the cultivated Roses:—

"Mr. Blunt, the British Vice-Consul at Adrianople, in his report to the Foreign Office this year, gives an account of the Rose fields of the vilayet of Adrianople, extending over 12,000 or 14,000 acres, and supplying by far the most important source of wealth in the district. This is the season for picking the Roses—from the latter part of April to the early part of June; and at sunrise the plains look like a vast garden full of life and fragrance, with hundreds of Bulgarian boys and girls gathering the flowers into baskets and sacks, the air impregnated with the delicious scent, and the scene enlivened by songs, dancing, and music. It is estimated that the Rose districts of Adrianople produced in the season of 1866 about 700,000 miscals of attar of Roses (the miscal being 1½ drachm), the price averaging rather more than 3*s.* per miscal. If the weather is cool in spring, and there are copious falls of dew and occasional showers, the crops prosper, and an abundant yield of oil is secnred. The season in 1866 was so favourable that eight okes of petals (less than 23 lbs.), and in some cases seven okes, yielded a miscal of oil. If the weather is very hot and dry it takes double that quantity of petals. The culture of the Rose does not entail much trouble or expense. Land is cheap and moderately taxed. In a favourable season a donum (40 paces square), well cultivated, will produce 1000 okes of petals, or 100 miscals of oil, valued at 1500 piastres; the expenses would be about 540 piastres—management of the land, 55; tithe, 150; picking, 75; extraction, 260—leaving a nett profit of 960 piastres, or about £8 11*s.* An average crop generally gives abont £5 per donum clear of all expenses. The oil is extracted from the petals by the ordinary process of distillation. The attar is bought up for foreign markets, to which it passes through Constantinople and Smyrna, where it is generally despatched to undergo the process of adulteration with sandal-wood and other oils. It is said that in London the Adrianople attar finds a readier sale when it is adulterated than when it is genuine."

WORK FOR THE WEEK.

KITCHEN GARDEN.

Asparagus.—The beds in full cutting—that is to say, in their prime, may have every shoot cut away until the middle of June. Sprue, or very small Asparagus, may, however, be permitted to grow. This will hardly prevent the development of the dormant buds. *Broccoli*, see to the sowing of Cape and other autumn Broccolis. *Celery*, let the plants in all their stages have dne atteution as to pricking-out, watering, stirring the soil, &c. Tha watering, above all, is a most important point; it should ever he borne in mind that Celery will grow in a ditch. *Kidney Beans*, make fresh sowings, for those above ground are not much to be depended on. *Capsicums* may he planted under the front of vineries or in other warm situations. *Tomatoes*, if hardened off, may now be planted out; the blanks on the walls are most eligible. Plant them on raised mounds, which will have the effect of reducing their grossness. Attend to the thinning of plants in seed-beds.

FRUIT GARDEN.

If wall trees, of the stone-fruit kinds, have been hitherto well managed, they will exhibit a regular development of foliage throughout. No time should be lost in removing superabundant shoots from any place where there are indications of an

excessive flow of sap. It is in vain to suppose that a branch already too strong will exhaust itself by throwing out a number of vigorous young shoots; on the contrary, the latter, if suffered to remain, will establish fresh channels for a flow of sap adequate to maintain their excess of vigour, and this appropriation must of course take place at the expense of the weaker portions of the tree. The fruit of Peach and Nectarine trees may now be partially thinned; that of Apricots should be finally regulated. Raspberries usually send up many more shoots than are ultimately required; the weakest should be removed. Let mulchings be applied where borders are shallow, or in any degree exhausted.

FLOWER GARDEN.

Newly-planted shrubs will require thorough watering in periods of drought. Masses of American shrubs under or near large trees should have a top-dressing of some kind to keep them cool, and to compensate for the exhaustion occasioned by the roots of the trees. A coating of bog earth, sphagnum, half-rotten leaves, or old tan, will be perfectly suitable. Conservative walls, trellises, or ornamental arcades, should have close attention at this period. The more tender kinds of plants newly planted out should be protected from sun and wind, and if cold nights occur, and mats cannot be had, Laurel boughs will answer the purpose admirably. When the various beds are filled the surplus plants will be invaluable for planting on rockwork, and for mixing with herbaceous plants in borders, arranging each plant according to the height it will ultimately attain, and keeping the very dwarf kinds in front. Examine choice Roses in order to ascertain that their buds are not injured or destroyed by maggots, and water with manure water during dull weather. Divide Neapolitan Violets, transplant into rich borders, and shade with a few boughs until the plants are rooted. Sow Brompton Stocks, Sweet Williams, single Wallflowers, &c. Tie up Pinks and herbaceous plants as they require it. Rake and clean shrubbery borders. Continue to tie up Carnations as they spindle, occasionally examining the knots and easing these when required; keep the pots free from weeds, and water with soft or pond water. It is injudicious to give what is termed "a little and often;" when water is applied give sufficient to moisten the whole mass. Pinks are rapidly advancing; tie to neat, thin sticks; reduce the spindles, or flowering shoots, to one or at most two; supply the plants liberally with water as the buds appear. Continue to propagate Pansies, transplanting seedlings as they become large enough. Attend to the directions given last week as to shading, watering, fertilising, &c. Some persons are in favour of watering in the morning out of doors, and others prefer the evening; we like the morning, as a general rule, more especially for plants which have been recently planted out, such as bedding plants in the flower garden, and young vegetables transplanted from the seed-beds in the kitchen garden. To saturate the soil in such cases is in our opinion highly improper, as leading to a considerable waste of the accumulated ground heat, also as tending to exclude the genial influence of the atmosphere. With regard to young stock of the above kind, frequent sprinklings are all that are required; in fact, a kind of cutting treatment, chiefly in order to prevent undue perspiration of the leaf. If this waste is prevented through the day by early morning watering, the plants may safely be left to the dews during the night. Fine-rosed pots should at all times be used, and light sprinklings repeated will prevent the soil from becoming puddled.

GREENHOUSE AND CONSERVATORY.

Towards the end of the month some of the hardier stock in these structures, such as the hybrid Rhododendrons, Camellias forming buds, and Orange trees in tubs or pots, may be set out of doors. This will give liberty to such of the stock as must be suffered to remain, both on account of their tenderness and of the display they make. A sheltered spot should be selected, but by no means under the drip of trees. A temporary awning should be suspended over them for a week or two at first, but it must be very thin. When they are reconciled to the change, such as the Orange trees may be removed to other situations in the open air. Heaths in full growth will at this period require abundance of water, at least in bright weather. Many good specimens are lost through imperfect watering. The Erythrina crista-galli is a fine old plant: cuttings may be made of the young shoots of subjects which have been headed down. The old plants started in heat in January, and now exhausted with flowering, if removed to a cool and light greenhouse and suffered to go to rest, will bloom well a second time in September by the excitement of heat and moisture after resting a few weeks.

STOVE.

The increase of temperature previously recommended, and absolutely indispensable in order to have many plants in perfection, will encourage the attacks of red spider, unless a keen eye is kept on every plant, in fact, on every leaf, and if allowed to go on unchecked it will soon destroy the foliage. Use the syringe daily, especially in fine afternoons, and this will do much to prevent the enemy appearing; but after it has done so recourse must be had to effective applications without delay. A rule in gardening, which ought always to be acted upon, is never to allow an hour, still less a day, to pass without making an attack upon some kind of insect on the very first discovery. The rapidity with which their multiplication proceeds, and of which all gardeners are well aware, should prompt to immediate action. Such of the stove plants, or those belonging to an intermediate-house, as have made a good and early growth, may now be removed to a cooler house, which will arrest their rapid vegetation in some degree, causing robustness of habit, and in many a tendency to produce autumn and winter flowers. Every attention should also now be paid to keeping down vermin amongst Orchids. There is nothing better than fresh, sweet bran for snails and slugs. This may be placed about the pots either in oyster shells or crocks in the afternoon, and should be examined by candlelight, at eight or nine o'clock.

PITS AND FRAMES.

After the stock for the flower-garden masses has been removed, all the surplus Verbenas, Fuchsias, Pelargoniums, Calceolarias, Petunias, &c., remaining in store pots should be potted forthwith in three-inch pots, and their cultivation should receive every attention. As soon as they grow freely they ought to be stopped, and be made to form bushy plants. These will form a reserve to succeed plants in full bloom at this period, and also to fill up gaps as they occur in the beds or borders.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The work has been for the most part a continuation of that of the previous week. As soon as the thunder-showers ceased every exertion was made to bring up arrears, and far enough behind we are, when we must confess that up to the time of writing this, even our flower-beds have not been levelled, though several times turned roughly; and without the loss of a single minute, the character of the winter and spring has rendered much out-door work rather behindhand, where there was not additional assistance. Our chief work in the kitchen garden has been sowing succession crops of Peas, Beans, Lettuces, Cauliflowers, Turnips, Radishes, &c., and more especially Dutch-hoeing all advancing crops, whether weeds appeared or not.

Temporary Hotbeds.—We are not at all sorry—quite the reverse—that some correspondents tell us we shall do much mischief by speaking of such beds as we sometimes do—made of litter and droppings as they come from the stables week after week, with less or more of short grass; and they end by advising us to recommend the good old plan of turning, and watering, and sweetening such dung before making it into a hotbed, "for then even young gardeners would not kill their plants with steam, gases, &c." Now, be it understood that we have no objection to all this labour, care, sweetening, and decomposing the materials so used; and no one has more clearly stated that the vapours from rank dung and grass will kill all vegetable life to which they can have free access, except some hard-stemmed plants, such as the Pine Apple; and therefore we have been careful that when beds are made in this way there shall be a sufficient covering of old dung, half-decayed leaves, or soil, that, whilst receiving the heat produced, will keep down all noxious steam. Whilst so used the bed made from fresh material is just as safe as one made from dung which has been frequently turned and sweetened for several weeks, and thus has dissipated in the general atmosphere a good portion of its heat instead of this being turned to use at once. On carrying out our directions there can be no danger, and we economise the heat from decomposing material which in sweetening are sent into the air. We also know that this sweetening process reduces the manure to something like a third of its bulk—a matter of importance where scarcely ever enough in its rough state can be found, and where bulk and a temporary heat must be made the most of.

Our greatest gardeners will be the first to admit that there is less head work, less constant anxiety and consideration required in large princely establishments, where there is the right place for everything, than in those where for a great many subjects which must be had there is no proper place—where, for instance, thousands of bedding and other flowering plants must be produced as extras, so much so, that an uninitiated stranger would suppose that these flowering plants stood all the year where they were found in summer and autumn. Now, for all such forwarding purposes a little heat from fermenting materials is of great advantage, and it is of importance to obtain that heat at once instead of waiting two or three weeks for it. Secure the heat, and, however rank, you can always insure safety by covering with older material, soil, &c. Mowings from the lawn are very rank, but mixed with long littery dung from the stable, much of the watering that otherwise would be required is saved. For instance, desiring to help on Celery, Perilla, Lobelias, &c., with the least trouble, and having a few sashes that had covered Violets and Calceolarias, at liberty, we had two or three loads of long littery dung, the produce of ten days, brought from the stable, made into a bed for six lights, the few droppings regularly incorporated with it, well trodden, and then well watered, about 4 inches of rotten dung from linings put over it, and then about 3 or 4 inches of soil. Some old trunks of Spruce trees too far gone to be worth saving, say from 6 to 8 inches in diameter, were placed back and front for the sashes to rest on; and a better place for pricking out such plants, to be raised again for final transplanting, could not be obtained in the finest pit in any garden, and the appearance of the plants shows how much they enjoy the by-no-means-violent, but genial, regular bottom heat.

For such work, lights of frames have to answer many purposes. For instance, in the case of early Potatoes in frames, the frame can be moved to something else before the Potatoes are taken up, and oftener long before the frame is moved the sashes may be turned to such purposes as above, and straw covers, &c., put over the Potatoes, Carrots, or Turnips at night, instead of glass sashes. We lately made some beds such as above described, but as we could obtain short grass we mixed that with the litter, and in such a case little watering was necessary, as the grass would yield the moisture. In a bed of this description, but with a frame for two lights over it, and prepared as above, we inserted Verbena cuttings, the upper covering being rough sandy loam, with drift sand on the surface, and we have no doubt that in three weeks from inserting the cuttings, there will be strong vigorous plants to take up with good roots for planting. All such temporary beds will be anything but idle in summer. We have made beds of dung so sweetened as to be short indeed at making time, and though fully 6 feet in depth, have been disappointed in the heat not being continuous, with the help of linings, for Melons and Cucumbers, and we have made beds 2 or 3 feet less in height, of less worked, less sweetened materials, except at the surface, and these beds, without having to make linings, especially if water could be made to pass down into the beds, and air with it, would maintain a regular, and for a longer time genial, heat than the thoroughly worked and sweetened manure-bed. In short, let every one work his dung as he thinks best, but let the amateur rest convinced, that he may sweeten it less with perfect safety and, therefore, obtain more heat from his limited supply, provided he keep the noxious gases down instead of letting them into the atmosphere among his plants and cuttings. For instance, there are numerous hardy plants, such as Pinks, Wallflowers, &c., which he may strike from cuttings now in the open air, in sandy soil, and especially if covered with a sash or a hand-light; but all these will strike sooner, and the plants be stronger if there be a little bottom heat below them, even such as may be obtained by a mixture of short grass and stable-dung placed in a hole. When we used to grow Castor Oil plants, Cannas, Daturas, &c., out of doors in the flower garden, we found success was greatly owing to giving them two or three barrowloads of such rank hot stuff beneath them, which afforded heat to the roots at starting, and became rotten enough for them to feed in before the end of the season.

FRUIT AND ORNAMENTAL DEPARTMENTS.

In these the work was chiefly a continuation of that of the previous week, but besides edging and preparing flower-beds for planting about eight days hence, as experience has told us there is little gained by hurry, when now most of the plants are in the ground in temporary beds, we have been anxious to finish with two matters, and trust to have done so before this is printed. First, we shall not be able to mow all the lawns and pleasure grounds, but we have mown a good swathe by the sides of all the *walks*, and this done early, and repeatedly is one of the great secrets for keeping walks clean, firm, and free of weeds; and the second matter is to cut with an edging iron the sides of all walks, using a line, and taking off as little as possible, but enough to show a clear edge. If the walks are, as they should be, not more than 1 or 1½ inch below the grass verge, the sharp-cut edging, though repulsive to fine taste, will not show more than a few days, and that eyesore is twenty-fold compensated by the ease with which such grass edgings are clipped throughout the summer.

There is another proceeding which we would recommend to amateurs if they wish such walks to remain neat after cutting the edges. This cutting will leave the sides a little coloured, and more earthy than the walk as a whole. Scatter a little salt for 6 or 9 inches in width, and on this a little sandy gravel. The sides of the walk will thus be neat and clean, will be easy to sweep during the season, will after a sweeping or two become of the same colour as the main part of the walk, and, as a rule, these sides will be free of small weeds, where otherwise they would be almost sure to vegetate. If in pleasure grounds the grass close to walks is allowed to become long, and produce seeds, it is next to impossible to keep the walks free of weeds. —R. F.

CRYSTAL PALACE.—The Great Flower Show, one of the events of the London fashionable season—is appointed for Saturday, May 25th. As this is the first great show of the year, and as the recent warm, sunny weather has had a most beneficial effect upon the flowers, the show, it is anticipated, will be unusually fine. It also enjoys the advantage of being fixed for the day appointed for the celebration of Her Majesty's birthday.

COVENT GARDEN MARKET.—MAY 22.

HOWEVER much the weather may vary, we have no diminution in the supply, the growers' stands being filled to a late hour each morning, or it may be the limited amount of business that is doing which makes the quantity seem so much greater. We have now from the Continent, Peaches, Apricots, Cherries, Melons, and a few Pears, Kidney Beans, Carrots, Turnips, Cauliflowers, Artichokes, and Tomatoes; new Potatoes from Lisbon, Malta, and the Channel Islands. Good Regents of last year's growth command a ready sale.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Golden-veined Violets (*Oakley*).—The leaves you have sent to us are very beautiful, and, as they have been similarly golden-veined in two following years, the sport is probably permanent. If so, instead of "preventing it," we think some one of the London florists would readily purchase the whole of your plants.

Cover for Vol. X. (*W. C.*).—If you enclose fifteen postage stamps with your address to this office, you can have the cover sent free by post. As the Vine mildew has appeared in your vinery, dust all the leaves with flowers of sulphur without delay. Syringe at the end of a week, and repeat the treatment until the mildew ceases to appear.

Advertisement (*R. G. Oakley*).—It is in our last number, but from "Roberts & Sons"

Aspects (*J. H. H.*).—For the purpose you mention, we would decidedly use the south-east wall in preference to the north-west. We cannot state the amount of piping in Mr. Meredith's houses which do so well, both on the east and west aspects. Piping must be regulated according to the time the fruit is wanted.

Coleus Verschaffelti for Bedding (*J. J. G.*).—Coleus Verschaffelti will do as a "bedder" in a tolerably sheltered place. It does well about London, and was very fine last season at Woburn Abbey. Mr. Fish has done little good with it in his windy position, but means to try it further. It would be well to keep some Perillas in reserve. The specimen you sent was of Bougainvillæa spectabilis.

Covering Hot-Water Pipes for Bottom Heat (*C. W.*).—Your proposal to place first a layer of stones round and a few inches over the pipes, then rough tan, all the finer part being sifted out, and at the top for plunging the pots either the fine tan or sawdust, will answer admirably, provided you take care that the rough tan over the stones that surround the pipes does not become dry; then it will permit the heat to rise freely. The moist state you may secure by having a pipe by means of which you can pour water among the stones. Do not cover the pipes with stones deeper than you can avoid—say 3 inches. We would put washed fine gravel over the stones, and then the tan would not find its way among the larger ones.

Tiffany (*Tiffany*).—It was advertised in our Journal last week.

Peach Trees almost Destroyed (*G. E. T.*).—Probably the Peach trees are suffering from the severe frosts. We do not think that the early pruning would affect them. We have lost shoots which were not pruned at all. In your case, with water standing so near the surface, at the other side of the wall, we should imagine that the border would be too wet, and the wood, in the late dull autumn, imperfectly ripened. A drain in front, from 3½ to 4 feet deep, would be the best remedy. There are very singular facts in connection with water in certain positions. Water stands as near the surface at the highest end of Mr. Lane's celebrated orchard-house vinery.

Insect Eating Rose Leaves (*P. P.*).—It is a Curculio, or Weevil, which eats the leaves of your Roses. We think it is C. maculatus, but the specimen was too much crushed to be certain. Spread a white cloth at night beneath the trees and shake them. The insect feeds at night.

Blistered Peach Leaves (*A. M. W.*).—Pick them all off. They are caused by cold checking the growth of the leaves whilst the supply of sap from the roots remains unchecked. Shelter by glass or other covering is a preventive of blistered leaves.

Heating a Melon Pit (*Learner*).—The brick pit 9 feet wide and 3 feet below the ground level, which you have used for Melons, and as you cannot heat with dung and tan you propose to heat with a flue, we would treat in this way. We would run a flue round on the floor, 2 feet from the front and 2 feet from the back. Above the flue, flow and return, we would make a floor 3 feet from the glass. Slate or stone would be best, but stout slabs of wood would do very well. We would lay these slabs so that there should be from 2 to 4 inches between them. These spaces we would fill with clinkers, brickbats, &c, and rough plaster them. On this platform we would place in the centre of each light, back and front, an open drain tile, or a wooden box, communicating with the chamber in which the flues run, and furnished with a lid to let out heat for the atmosphere as wanted. By pouring water into these openings you can have moist bottom heat at all times, and moist top heat as you want it; and there will be no danger of scalding, as the water will not touch the flues. For this system, if the flue is built, raised a few inches above the floor, the water poured on will go over the whole of the floor. If the floor was concreted all the better. The 3 feet will give ample room for foliage and earth. There would be more trouble in heating the two divisions of your 18-feet pit separately, but you can commence with that next the furnace, and give plenty of air to the farther part until you wish to start it. The air makes all the difference. We observe no red spider or other insects on the Vine leaf, and the blotches are the result of scalding. The best remedy is early air-giving.

Variegated Loeelia (*J. B. P.*).—We cannot form an opinion upon such a specimen. Send a good plant in a pot to the Floral Committee of the Royal Horticultural Society.

Grapes Dark Coloured (*J. S. H.*).—Though no bigger than Peas, they are severely "spotted"—that is, they have a peculiar ulceration which gardeners call "the spot." We believe it to be caused by defective root-action. If the roots are kept warmer and better nourished we think the evil will not reappear.

Dahlia Culture (*Dahlia*).—We shall readily give information to any grower of this flower; but we do not know of any difficulties in its culture.

Covent Garden Market (*J. Woods, jun.*).—We know of no such person as you need. The regular attendants will not incur the trouble of commissions.

Pampas Grass Drying (*W. R. J.*).—The stems required for ornamental purposes should be cut directly the flower-heads attain their full size, and should be dried in the sun. We can only account for the glumes or valves falling from their being cut when mature; washing them with water will not tend to their preservation.

Tree Mignonette after Flowering (*M. S.*).—Mignonette is a perennial in a greenhouse, and after flowering may have the surface soil removed and have a top-dressing of rich compost, the plant being kept closely pinched; but it will not flower nearly so finely as plants sown and grown on for the purpose. The flowers are smaller, and the plant less vigorous.

Eucharis amazonica Culture (*C. M. Major*).—The plant should have a rest, which you may give at any season after the plant ceases growth by withdrawing it by degrees from the hotbed, and keeping the soil dry, but not so as to cause the foliage to flag, and it cannot have too much light and air. The pot, we presume, is full of roots and the drainage good. If the plant is growing do not check it, but allow the growth to be made; then when the foliage attains its full size lessen the supply of water gradually, and expose the plant fully to light and air. This will check the growth, but you must not lessen the amount of water so as to cause the leaves to flag. It should have a rest of this kind for three months in every year; but probably your plant will soon bloom.

Pancratium and Ismene amancæs (*Idem*).—The Pancratium requires precisely the same treatment as the Eucharis. The Ismene amancæs also requires the same treatment as the Pancratium, to which it is a closely allied species. You cannot give them too much encouragement when growing, nor ripen off too well by full exposure to light. The potting should not be too liberal, for they flower more freely and certainly when the roots are confined.

Rhododendron Falconeri Injured by Frost (*A Subscriber*).—You may take up the plant from the open ground now, and you may cut it in, this being a good time, and it will start better from the part protected by the snow than from the leafless portion of plant, that being the part injured by frost we presume.

Soil for the Orange, Lime, Shaddock, and Camellia (*Idem*).—You cannot have a better soil for all those than the surface of a good and rather light loamy pasture, the turf being cut off from 1½ to 2 inches thick, and being chopped and made pretty fine with a spade. It should be used fresh, and the border should be well drained, and in planting the ball of each should be loosened and the fresh soil worked in amongst the roots. The soil should be made firm about the roots. They should be planted rather high, as the soil will settle. Camellia Valtevaredo is a plant of fine habit and foliage, having finely-formed rose-coloured flowers.

List of Rock Plants (*Buz*).—Achilleæ Clavennæ, silvery foliage and yellow flowers; Alchemilla pentaphylla, greenish yellow; Alyssum saxatile compactum, yellow; Antennaria, silvery foliage; Aquilegia alpina, purplish blue, with white centres; Arabis alpina, A. albida, A. lucida variegata, A. caucasica variegata, all with white flowers; Aubrietia deltoidea grandiflora, lavender blue; Campanula garganica, purple; Cerastium tomentosum, white; Cheiranthus alpinus, yellow, C. Marshalli, orange; Cistus formosus, yellow, C. Ledon, yellow, C. roseus, rose; Convolvulus mauritanicus, blue; Cyclamen coum, red; C. repandum, rose-colour, C. europæum, rosy pink, C. neapolitanum, red; Daphne cneorum, pink; Dianthus floribundus, pink; Draba aizoides, D. hœmtica, both yellow; Dryas Drummondi, yellow; Erinus alpinus, rosy purple; Genista procumbens, G. triquetra, both yellow; Glechoma hederacea foliis variegatis, reddish pink; Gnaphalium hyperboreum, white foliage; Iberis saxatilis, I. sempervirens, I. Tenoreana, all white; Linaria alpina, bluish violet, L. cymbalaria variegata; Lotus corniculatus flore pleno, yellow; Meconopsis cambrica, yellow; Mimulus cupreus, orange; Orobus vernus, purple; Oxalis tropeoloides, yellow; Phlox Nelsoni, white, P. verna, rose; Polygala depressa, blue, P. vulgaris, bluish purple; Rhododendron hirsutum, pink; Rubus chamæmorus, white, ornamental edible fruit; Saxifraga æmois, brownish crimson, S. aizoides, yellow spotted orange, S. biflora, rosy purple, S. caryophylla, white, S. cotyledon, white, S cymbalaria, sulphur spotted orange, S. hirculus, yellow, S. juniperiana, yellow, S. oppositifolia, rose, S. umbrosa crenata, white; Sedum acre, anglicum, cruentum, Ewersii, and virescens, all yellowish; S. purpureum, purplish rose, S. pallidum roseum, light pink, S. albicans, white; Trifolium alpinum, rose; Vinca herbacea, V. major, V. major elegantissima, V. minor, V. minor plena, all blue. Of all of the above you may procure plants, but some of them may be raised from seed. It is best, however, to obtain plants. They all will succeed well in a rather shady situation, but not under trees.

Japanese Maize (*Idem*).—We presume it is the variegated variety about which you inquire. It attains to a height of 6 feet and more, and is not, therefore, suitable for edgings. It is very finely variegated, and well worth growing. It requires a warm, sheltered situation, and may be used as a centre to a large bed, or at the back of a ribbon border, and it requires to be sown each year, and in heat, so as to get it strong before planting out.

Australian Spinach (*Idem*) —It requires to be sown in heat, and when strong planted out in good rich soil.

Sorghum tartaricum (*Idem*).—It is a tall-growing Grass, of no use in our climate but as fodder for cattle.

Cape Aster (*Idem*).—Cape Aster, or Agathæa (Cineraria) amelloides cœlestis, is an evergreen, low-growing shrub, attaining to a height of 18 inches. It flowers very freely; the flowers of a bright blue. It requires to be wintered in a greenhouse; is raised from cuttings of the half-ripened wood placed in a mild hotbed. It cannot be raised in the open border.

Delphinium formosum (*Idem*).—The seed of this lovely bright blue-flowering plant may be sown now in an open border, and when the plants are large enough to handle they should be pricked off in a bed of good rich soil about 3 inches apart, and in autumn planted where they are to bloom. The seed may be sown in March in a hotbed; the plants being pricked off when large enough to handle, and grown on, will flower the same year.

Six Select Perennial Phloxes (*Idem*).—Purity, white, carmine centre; Madame Thibaut, crimson, dark centre; Picturata, rose, centre marked crimson; Madame Corbay, white, violet centre; Beatrice, carmine crimson, and Madame Lemort, violet mauve, flaked with purple; another good one is Triomphe de Twickle, carmine, edged white.

Sea-kale Bitter (*S. J. T. E.*).—We should attribute the bitterness to something deleterious in the ashes, which are not a desirable material for blanching it. Sand is far better, and nothing is equal to pots covered with litter. Perhaps the Sea-kale was imperfectly blanched; it would then have a strong bitterish taste.

Names of Plants (*Llanvedyn*).—Tellima tenella. (*Bournemouth*).—Halesia tetraptera. (*B. P. J.*).—Trillium grandiflorum. The "Manna" is Oplismenus crus-galli. (*G. A. F.*).—Ledum latifolium. (*J. P.*).—Daphne cneorum. (*P. E. F.*).—1, Ledum latifolium; 2, not determinable; 3, Staphylea pinnata.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending May 21st.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE STORY OF THE BLACK BANTAMS.

Cousin Janet took a fancy she would have some chickens of her own. She had an idea that I had derived great pleasure and profit from my White Dorkings, and being of rather a speculative turn, she would make the venture; so one morning early in April she sent a maid across to South Field, to borrow one of our White Dorking hens to sit upon some Black Bantams' eggs she had that morning received from Brighton.

"A White Dorking weighing 7 lbs. to hatch Black Bantams weighing a few ounces—absurd!" said papa; "I hope you told her so."

"No, I did not."

"Then you would have done the greatest kindness to have said so. They have no convenience for poultry-keeping at Uncle Tetley's, and cannot succeed."

"I can tell her so yet, it is not too late; only I am afraid Cousin Janet will think me mean and ill-natured."

"And if you do," said Aunt Margaret, who was with us at the time, "she will miss the knowledge she might have gained by experience. Ah, Maud! if you live to be an old maid you will find out it is much better to let people have their own way—read their school-books after their own fashion, upside down if they chese."

"If I were you, Maud," suggested mamma, "I would send in the hen and your 'Poultry Book,' and ask her to read it, so that she might know what she was doing."

"Janet will bring up her chickens and then read the book," said papa with a great laugh; "and snub you into the bargain for seeming to know more than she does."

But Cousin Janet did not do that: she accepted the hen with a long string of compliments, but returned the book with many thanks, saying she "did not need it—had more than she could read, and that she knew all about poultry-keeping, having once visited at a farmhouse for three months, where they kept a first-rate housewife."

So the Dorking was taken to her new quarters. She had long cherished the desire to have a family of her own; yet when shown the nest containing more than a score small, very small eggs, she manifested great discontent—seemed by instinct to know that they were not her eggs, and would not produce her sort of chickens. So she grumbled and cackled, and flew up and down; and though over and over again she was taken to the nest, still it would not do—they were not her own eggs, and it was not her nest. She was not like the little Game hen that stole a nest in a manger, and, when the eggs were found and removed, took the halter ball under her wing, and kept it warm for days and nights; so determined to sit was she, that anything was better than nothing. There was no way for it but taking the hen back to her old nest and seeing if that would bring about the desired result. Even then she did not seem exactly suited, but scratched about among the eggs, turning them right and left. Some rolled out—they were given back to her; again she rolled them out more roughly than before, for this time they were broken. At last she was left in quiet possession of sixteen eggs, over which she brooded, and evidently intended to take great care. Whether the Dorking was gifted with numerical qualifications, or was a believer in the old saying, "There is luck in odd numbers," I cannot tell; but when she left her nest the next day there were seventeen eggs—a large round white one in the midst of the small ones: this was taken away. Next time the eggs were counted there was still an odd number, another large white egg being added; but this time it was left to take its chance—no doubt it would come on well. It was a great favourite: it was always found in the warmest, softest part of the nest—no daily turning over of the eggs ever turned it to the outside.

As the twenty days passed the wonder was, how many chickens the Dorking would hatch out of her seventeen eggs. She had not broken any, but the critical time was yet to come, and, which appeared far more likely to have happened, Cousin Janet had not broken any. Never "sitting hen" had such a life of it as the poor Dorking had. Many a time did I wish she had been a Game hen, better to have defended the rights and quiet of her nest. Of course the hen and eggs had been removed to Ridge House as soon as the former had settled. Every egg was marked on one side "up," on the other "down," and daily did Janet take off the hen to see if the eggs were all as they should be, all "up" or all "down;" if not, they were turned over to the proper side, for the days when they should be "up" or "down" were marked in her almanack, so she "could not forget if the hen did." Then every four days the nest was watered with warm water, and, when the last week arrived, daily. Then every night a candle was taken into the outhouse and the eggs looked through. All the eggs had the same appearance—they were either all good or all bad; Kate said the former, Janet the latter. So a basin and warm water were brought to test them; for George said, "If they sank they had chickens in, the weight carried them down." Cook said, "If they had chickens in they would float, for as soon as the bird felt the influence of the warm water it kicked about, and the motion kept it up." George said he could not tell how anything so tightly packed as chickens were in the shell could possibly kick. "Why, then," replied cook, "they breathe faster, and that moves them about."

Kate thought "nothing could breathe without air," and she did not see "how the chicken could get any through the shell and the thick underlying skin." Aunt Margaret thought "every egg contained a certain portion of air kept in reserve for the growing bird."

So, with so many different opinions, Janet was puzzled and refused to try the warm-water test.

"And when they snip," said Janet, "what would you do? The hen has so many I am sure she cannot take care of them all. I have heard say you may help them out by wrapping them in a warm, moist, flannel; and there were four with little holes in this morning. I will try."

"But, why would you take all that bother when the hen can do it for you so much better?" said Aunt Margaret. "I would leave her quietly alone to do her own work; and if you must help, just take away the little chickens and put them by the fire, and then the others will come on faster."

During the day four of the chickens were put into an old hat and placed before the kitchen fire, covered over with flannel. The brimful kettle was hanging up over the fire, its low-set and yet far-projecting spout already filling with the swelling water; a few minutes and it boiled over, pouring out its scalding contents right into the hat, which seemed to have been placed there on purpose. The poor little Bantams' short lives were soon over.

Next morning there were five more chickens out of the shells.

These were pnt into a basket and taken into the parlour, where there was no kettle to boil over. During the day four more came ont, and the one White Dorking; and in the evening Janet was in a great dilemma. What should she do with her Bantams—roll them up in fiannel and put them in the oven all night, or give them back to the hen? Everybody thought they would be trampled to death before morning, and yet she must have them sometime, so why not at first? Next morning Janet found two of her chickens dead, and one egg squeezed so flat that the bird was killed; aud the two remaining eggs though chipped did not appear to be making any progress, and certainly had not much chance, for their mother did not care about them in the least; she stood upon her legs, shook her wings, and walked about and called her little ones after her, aud finally settled down in a corner, as far away from her nest as could be, appearing only to have one desire—to thrust her tail right through the stone wall out into the garden.

What could be done with the forsaken eggs? Janet was sure she could bring them out alive, saying it only required time, patience, nicety, warm water, and a pair of very fine scissors; and Janet had one and all of these. So she made the trial, and sat for hours in the hot sunshine of a May day by the table on which was placed a china basin containing a little warm water in which were the eggs. When the water cooled she added more warm, then took out one egg and wrapped it in cotton wool and put it on the stove. Every few minutes she opened it out to crack the shell a little more, or to break off pieces that were already cracked, until the bird had its feet free, and then could help itself. Then the other egg took its turn under the operator's hand.

Time and patience indeed worked wonders beneath Janet's delicate fingers; and when the evening came the chickens were out of their shells and alive. Poor little weak things, they looked unable to hold up their heads or stand upon their legs, and very proud was Janet when she took them to their mother; but the Dorking was unwilling to regard the new comers as her own; she would not shelter them, and they were afterwards given to her in the dark, so that when the daylight came she could not know them from her own.

Janet's hen-house, a temporary place made of wood, which George had put up, was one of those clean places, all too clean for chickens. The poor hen could not find a fly or spider on the fresh lime-washed walls, and the floor was constantly scoured out with stones as they do in Yorkshire, so that the Dorking might scrape and scrape, and yet find nothing, not even a bit of hay, or grass, or straw to make a nest of, or to toss about for pleasure as mother hens love to do. There was not a grain of sand or speck of dust—nothing in the world for the hen to do. She could not even turn over the fountain, it stood so firmly; and the dish containing their food was too shallow to be upset, so there was nothing left for the chicks but to paddle in and out among the bread and milk, and waste much more than they ate.

A fortnight passed, there were no deaths to register in Janet's poultry book; if the Bantams did not thrive and grow, they at least lived. Cook said, "They never would be worth anything in the world. They wanted more air and sunshine; they ought to have fresh green sods daily from the field to peck at and play with, and thus give them something to do besides eating and sleeping." So on the first fine day Janet gathered up all her chickens into her little black silk apron, and took them out into the garden to sun. They could not have sunshine in their little house, so she would give them an airing; but the chickens did nothing but fret and make a great noise, which their owner bore with admirable patience, thinking it was for their good. At the end of half an hour she took them home to their half-wild mother, who in her anger at their absence knocked them about right and left, rapping them hard with her bill, covering them with her wings one minute, and the next sending them adrift, scolding all the time, until the poor little Bantams began to wonder, like Trotty Veck, if they had any business in the world.

But a darker day was drawing near for the chickens, a day ever to be remembered; it was when they were nearly a month old just the age when mortality runs riot among them, carrying off the weakly ones, and testing the strength even of the strong. It was a rule at Ridge House to take in a good feed every night for the little things to find early in the morning, so that Janet had no need to go to them until after breakfast. One Saturday night the rain came down in torrents, so the maid put aside the food, thinking she would take it by-and-by. She never remembered to do so. Next morning the bells were ringing before Uncle Tetley or any one, save Aunt Margaret, made an appearance to breakfast. There was a great hurry and fuss to be at church in time. Then after service it was pleasant loitering slowly home through the country lanes. Janet seemed to find it so, for she was slower than any one. Then came the dinner earlier than usual, for Cousin Walter had undertaken to teach a class in the Sunday school for a friend who was away in London. Then there were cake and wine and fruit, the good things which could not be hurried from, so that it was three in the afternoon when Janet sought her Bantams, not to see if they wanted anything, but for her own pleasure, unlocking the door and going in, without any foreboding feeling of coming sorrow. She called out "chick, chick," and the hen flew up and bit her wrist, and no wonder, for the floor was strewn with her dead chickens, three, four, five of them, another gasping out its last, its head resting on the empty fountain. There was not a crumb of bread, or groat, or bit of rice to eat, nor even a sod to peck at in desperation, and the few Bantams that were alive crawled feebly after their mother.

I am afraid we did not sympathise much with Janet, for Aunt Margaret called her a cruel girl to pine her chickens to death; and cook said, "There was little sense in crying after spilled milk, and that all the wailing in the world couldn't bring 'em back;" and "Janet declared it would not have happened if she had not trusted Mary to do it;" and Kate said, "Janet never would succeed with poultry because she regarded them altogether from a wrong point of view. She thought of her own pleasure, not their good."

After this Janet took great care of her three Bantams, she gave them sand and sods, and fresh water, never forgot to feed them, and never again separated them from their mother, but took them out into the sunshine for hours; but the evil done was in a measure past remedy, a pined chicken seldom recovers. One of the three sickened and died before it was two months old; another, a little hen, grew up deformed, its back was crooked, and its tail on one side. Only one grew up of fair proportions, a fine little fellow he was, loud in voice, quick of motion, and with a coat glossy as an old starling's. A general pet was Master Charley; he would spring on your hand, eat out of your fingers, and betray no fear nor desire for liberty.

When the mother Dorking left her Bantams, which she did not do until her new nest was half full of eggs, then the Bantam hen drooped and pined away, and was at last found dead under some rhubarb leaves. Master Charley did not miss her much, she was no companion to him in his long strolls through the fields, or his high flights upon the walls, where he used to beat his wings and crow out lustily, with a voice like a giant's. But Charley lost favour, he was a great thief, and the thing he liked best to steal was butter. Many a time in a week was he found upon the kitchen table digging his bill deep into the soft new butter. So Aunt Margaret said it would be best to send him away. He was taken to a farm-house a few miles in the country; but he did not settle there, he missed the old faces, and moped about in corners, hanging his wings and tail, and was never heard to crow. He had not been there many weeks when he was drowned in a tub of wort. He was then put into a basket, and sent home. We dug a hole in the Vine-border, unreached by Vine roots, and as near as we could remember to the fifteen Bantams, and we buried him there. Janet said "she was sure the eggs must have ailed something, or all the chickens would not have died."—Maud.

CAVE CANEM.

(FOR CANEM READ CAMBERWELL.)

In the beginning of the year I advertised some Game Bantams for sale. I was kindly answered by a gentleman who had evidently his "little place in Surrey," not far from "The Green," and that pellucid stream known as "The Canal." I was requested to send some birds immediately, and to write word by what train they would arrive in London. "An acceptance at three days" was promised by the next post. There was something so "truly rural" in the whole affair that I could not do otherwise than exclaim with Charley Bates, "So jolly green!" Thereupon I sent two letters, the one saying that the birds would arrive in London by such and such a train, the other to a "denizen of 'The Grove,'" a little bird who whispered by return of post unsatisfactory things.

I did not send the birds. In a day or two after the time when they should have been delivered, I had a letter to the

effect, that if I had not sent them I was not to do so at present, as my correspondent had failed in disposing of some birds, and had not room for them.

After a while, when I had almost forgotten the matter, I received a note requesting me to send some pens immediately. I wrote asking for a cheque or a reference. I heard no more. There used to be a phrase, "It's all up at Peckham." I suppose this was the case at Camberwell.

The inquiry in last week's Journal concerning Camberwell brought the matter to my recollection.—EGOMET.

WOODBRIDGE POULTRY SHOW.

I WAS much gratified to see by the letter of your correspondent "EGOMET," which appeared in last week's Journal, that the Committee of the Woodbridge Poultry Show now purpose to discharge in full all outstanding claims. This is a step that will, no doubt, insure a perfect reconciliation with all claimants, and also public support, should it be deemed advisable to resuscitate the Woodbridge Poultry Show. That the Committee were placed in a most unenviable position during their last Show, from the fact of a sudden gale of wind overturning the tent, is probably known to most of your readers, and, doubtless, a very heavy reduction in the receipts from this unforeseen cause ensued, independently altogether of the great personal annoyance to the managers themselves.

The Committee having adopted their present course, I cannot forbear (as having arbitrated at so many of their meetings), giving my unqualified approval of the great care and attention bestowed on the poultry during the time of exhibition, which, in fact, could not be exceeded; nor can it be doubted the institution of the Woodbridge Show did much to improve the poultry in the surrounding district.—EDWARD HEWITT.

ARTIFICIAL HATCHING.

I SHOULD feel greatly obliged if some of your readers who have had personal experience and success in artificial hatching would kindly tell me what they consider the proper temperature for eggs. I presume there would be a difference in cases where the whole of the egg is constantly exposed evenly to the same heat, from those where only one side receives the greatest degree.

What should be the temperature when the egg receives on all sides the same heat? and when one side receives a greater degree, of what temperature should the hottest side be?

An old book which I have on the subject states, that to have strong birds there ought to be a difference in the heat applied to the top and bottom of the egg of from 8° to 10°, but I cannot believe there should be so great a difference.—K.

[There need be no attempt made to secure a difference of temperature between the upper and under side of an egg whilst incubating. When a hen sits upon eggs the temperature around them is uniform. The temperature should be 104°; but 2° or 3° higher or lower occasionally are not detrimental, and if once in each twenty-four hours the temperature for half an hour is allowed to sink to 90°, in imitation of the hen's leaving the nest for feeding, all the better. This lowering of temperature must not be permitted during the day or two during which the chicks are coming out of their shells.]

RIVAL INCUBATORS.

I THINK most of your readers will agree with me that one of the greatest drawbacks to poultry exhibitors is the difficulty of obtaining early chickens. Cochins are the only fowls which can be safely relied upon as sitters in the early part of the year, and they frequently crush one-half of the chickens in hatching, and clumsily tread some of the others to death afterwards. Moreover, to fanciers of a non-sitting variety, the necessity of keeping sitting hens which are useless for the greater part of the year, is a great inconvenience. This obstacle seems likely to be overcome in a great measure by artificial incubation, the great difficulty being to select from among so many incubators, new and old in principle, that best adapted to the purpose. I would beg to suggest that, alive as you always are to the interest of exhibitors, and holding the position of the recognised authority in poultry matters, you should kindly intimate to manufacturers of incubators that you would be willing to experiment with the different incubators, and report on the merits of the same after the manner of *The Field* trials of breech-loaders and sporting rifles. I feel persuaded that your kind compliance with this suggestion would be a great boon to very many subscribers.—BROWN RED.

[It was an easy task for our sporting contemporary to decide on the merits of rival rifles; but to watch incubators for three weeks would require an expenditure of time which we cannot afford. Moreover, we think that if three disinterested breeders of poultry would undertake the task their decision would be more satisfactory.—EDS.]

NON-RESISTING BEES.

A FEW weeks ago the attention of bee-keepers was directed to the subject of non-resisting bees. That the bees of a hive well stored with honey and a numerous population should allow themselves to be tamely plundered by marauders, without offering any opposition, is certainly an anomalous proceeding; but that such is the fact I am able to attest from personal observation.

In the early part of February last, my attention was directed to bees deliberately entering a hive and carrying off the stores without challenge. They came from a colony a few yards distant, as was proved by sprinkling them with flour, and the circumstance of their meeting with no repulse from the inmates led me to suppose that they had found out a queenless hive. An inspection of the interior, however, proved not only that I was mistaken in my conjecture, but disclosed the gratifying truth that an active queen reigned, and that there was no lack in the number of her attendants. Although, however, the population was such as to be capable of defending itself, it yet in the most unaccountable and helpless manner allowed its treasures to be pillaged. For two weeks a regular system of pilfering was established, and not till the unfortunate inmates were reduced to the verge of famine did they awake from their apathy and become alive to the evil that had befallen them. Then, when almost too late, a change of sentiment took place, for on the return of the thieves to complete their work of ruin, they were met at the entrance, collared, and stung to death, or hurled over the landing-board.

So discouraging was the reception from their enraged victims, that a timely retreat was deemed advisable and a truce was entered into for the future; but as the stores had in a great measure disappeared, I found it necessary to replace the emptied combs by some well-furnished ones which I had laid aside as a reserve for any weak stocks that might require a little help in spring. The new supplies kept up the spirits of the bees, and they were not again molested by their former assailants.

All went on well till the 22nd of April, when the hive in question for a second time became the victim of misfortune. Thieves again found a peaceable entrance to it, but this time they came from a different colony—one that occupied the site farthest from it in the apiary. The weather was favourable for making incursions, and the new thieves continued them daily till the 28th, when a grand and final siege was laid to the sweets, and the whole carried off without remorse.

What struck me as rather remarkable was the fact that not only was no defence by the assailed set up, but that they never seemed to intermit their labours for a single minute during the commission of the depredations. Pollen was as diligently carried in as honey was carried out, and the queen, without showing any signs of perturbation, pursued her maternal duty of oviposition. Not one intruder attempted to injure her, and the unfortunate bees seemed to have no concern but care for their brood, of which there was a considerable quantity in the hive.

As the food was now exhausted I knew a hunger swarm might soon be expected, and therefore to prevent so undesirable a result, I provided the hive with my last spare comb, and removed it to another apiary a mile distant, where the persecutors of the inmates would have little chance of finding it.

Since its removal they have manifested great activity, and now that their foes have found that no spoil can be extracted from the vacated stance, these are wisely betaking themselves to legitimate labour.

Had it been earlier in the season I might have resorted to a remedy which in another instance of the kind was found successful—viz., to shut up the plundering hive one day and the plundered hive the next, continuing the practice for a week or longer; but in May every day is precious, and I was unwilling to retard the progress of either hive by causing a suspension of out-door work on alternate days for even a short period.—R. S.

"WHY DID YE DIE?"

On visiting the apiary of a friend in the county of Dublin this week, I was much disappointed to find that four very fine stocks were completely uninhabited, every bee in them having died. When I say fine stocks, I mean they were so at the commencement of last winter when the autumnal feeding ceased. At that period nothing could have been more prosperous than their condition, both as regards population and winter stores of feeding. All seemed to go on well during the winter, and at the opening of spring they each showed the usual symptoms of health and prosperity. Food in moderate supplies was then given to them, consisting of liquid honey and sugar and barleysugar made exactly as directed by Payne in his book on bees. My friend thinks the latter was the cause of the disaster, and that the bees were poisoned by the vinegar contained in it. Such, however, is not my opinion, though I confess I am puzzled to account for the sudden and rapid mortality which took place.

On opening and examining one of the hives, the appearance at first did not strike me as extraordinary, a fair quantity of honey in a perfectly pure state was still in store; there was no sealed brood-comb, but a number of brood-cells were open, and occupied by young bees, which had apparently come to perfection. From the latter, and also from a number of old dead bees clogged between the combs, a most offensive smell was perceptible, very much like stale salt fish. I also observed a white mouldy spot here and there, from which the odour I have described emanated strongly.

What do you consider the probable cause of the disaster? A stock of Ligurians adjoining the others are in a most flourishing condition; they had no barleysugar.—Squib, *Co. Kildare.*

[We do not believe the bees were injured by the barley-sugar, and should refer the offensive smell and spots of mould to the effects of decomposition after death. All the appearances you detail point to the conclusion that the stocks perished from cold and starvation, although how this could take place when the hives contained a fair quantity of pure honey appears almost inexplicable. We believe the fact to be, that the vitality of bees frequently recedes to a low ebb towards the end of winter, and in this way they often at that time succumb to a degree of cold which would have done no harm whatever at an earlier period, whilst the remaining stores of honey were probably in remote parts of the hives, which in their enfeebled condition they were unable to reach. We do not recognise in your description any symptoms of foul brood, and should not, therefore, be afraid to make use of the empty combs after picking out all the defunct bees and larvæ.]

THE GERMAN CENTRIFUGAL MACHINE.

FOR EXTRACTING HONEY FROM THE COMBS WITHOUT INJURING THEM.

Concerning this invention of Major von Krushka we find the following in "The American Bee Gazette." "M. Rouvel says, 'The whole secret is in making use of centrifugal force. The honeycomb is laid upon a wire sieve hanging in a funnel whose outlet is closed by a cork. The funnel has a handle or bail (like that of a pail or kettle), to which is attached a rope, by which it is swung round and round in horizontal circles; and after a short time the honey, if it is not too thick or crystallised, can be drawn off out of the funnel perfectly clear and free from particles of wax or pollen. For operations on a larger scale a stationary apparatus with wheels for motive power is needed; but for single combs any one can construct his own rotary hand apparatus.'"

Major Von Krushka explained his "Honeycomb-emptying Machine" at the meeting of apiarians at Brünn as follows:—"The whole matter is very simple; reminds one of the 'egg of Columbus,' and is founded upon the use of centrifugal force. You can convince yourselves very easily of this by trying the experiment on a small scale. Take a wire pipe-cover, place in it a little piece of unsealed honeycomb, tie a string to it, swing it round and round in horizontal circles, and you will see that the honey is very easily expelled from the comb. Founded upon this idea, I have constructed an apparatus which affords the most satisfactory results, and offers many advantages to those who obtain honey in large quantities. Among these advantages are—purity of the honey, facility in obtaining it, and complete preservation of the combs, which are often of such exceeding value to the apiarian.

"To give a general idea of this machine, imagine to yourselves a horizontal disc put in rotary motion by a wheel. Upon the edge of this disc are eight small uprights surrounded or connected by a wire sieve, and thus forming an octagon upon the disc. If you now hang the unsealed combs with their frames between these uprights on the inside of this wire octagon, and put the disc in motion, so as to make about six revolutions per second, the combs will be emptied in one or two minutes. The honey is caught in a circular tub surrounding the disc, and is drawn off at the bottom. With such a machine a labourer can easily empty in a day from 8 to 10 cwt. of unsealed combs, which by continuing the rotary motion long enough are emptied so thoroughly that they appear *perfectly dry*. The honey is much purer than that obtained by the usual cold process; has no pollen or other extraneous particles mixed up with it, and, therefore, keeps much better. An essential condition for the successful operation is a temperature of not less than 20° Réaumur (77° Fahrenheit); at a less degree the honey would be too thick, and the wax, especially new white wax, too brittle."

Herr Knoze in describing the advantages of this apparatus, declares that he *hopes* that the honey-harvest will be considerably increased, as the bees will have less to build and more cells to fill; he *knows* that dealers prefer honey thus obtained on account of its greater purity and clearness; and *believes* that it will take the bees less time to fill three empty combs than to build one new comb.

OUR LETTER BOX.

Making a Hen Broody (*F. H. M.*).—No kind of food renders a hen broody. A hen of any sitting variety will not be broody until she has laid her clutch of eggs. If you kept two or three Cochin-China hens you would rarely be without one wishing to sit at this time of the year.

Hens Eating their Eggs (*Trotters*).—When hens have taken to eating their eggs it is very difficult to cure them. They begin because they want the shell; they keep on because they like the flavour, especially the yolk. The only thing that seems to check them is to put some of the composition eggs that are hard as marble in their nests. We have done so, and have many times, when we had a pen inclined to eat their own produce, rolled one of these in their way, or put one in their nests. They peck and peck with redoubled force; they turn them over and over, and try all in their power, till they are weary and give it up. This is not always a cure, but it seldom fails.

Pairing Canaries—Chickens Dead in the Shelle (*Idem*).—It is not too late to pair Canaries. Your chickens die from lack of moisture. The eggs should be well sprinkled with water for a week before they hatch. If you neglect this you will always lose chickens.

Game Cock's Tail Pulled Out (*G. R. Smith*).—It will take at least nine or ten weeks for the cock to get his tail. Few birds begin moulting till July.

Hen with a Brood Laying (*H. W.*).—It is not an uncommon occurrence for a hen to lay whilst her brood, a month old, are with her. We once had a hen which laid and sat before her previous brood had left her. At night they rested in a circle round her nest. "Cocks' eggs," whether round or oval, are merely abortive products of some hen or pullet.

Blisters on Chickens (*E. F. W.*).—Your dietary scale is not good enough. We cannot say that the bread and water diet causes the bladders or swellings, but it is poor food, and poverty may have to do with the disorder. We feed our chickens on curd, bruised corn, chopped egg, bread and beer, and meat scraps chopped fine. "All is fish that comes to net" in the way of food for chickens; and with them, as with human beings, a change is desirable. We had a few cases like those you mention last year, and most of them recovered. Those, however, that we tried to treat all died, especially those we punctured.

Colour of Game Hens' Combs (*Idem*).—Game hens should have well-serrated, straight, and red combs. There are, however, some breeds that have lead-coloured combs, and they are correct.

Pheasants Roupy (*P. P.*).—Remove them to a fresh spot where they can have plenty of grass. Give immediately a pill of camphor the size of a pea. Repeat it in eight or ten hours. If the eyes are swollen and closed, wash them with cold water and vinegar. Feed sparingly on stale bread steeped in strong old ale.

Churn.—*An Old Subscriber* wishes to know which is the best churn to make from 2 to 12 lbs. of butter. We shall be obliged by some of our readers stating their experience on the subject.

Error.—Page 302, col. 2, line 29 from bottom, for "Bark" read "Dark."

Bees in Neighbour's Hive not Working in a Super (*G. J.*).—We do not see what more you can do to induce your bees to ascend unless you pour a little liquid honey into the guide-comb. Little time, however, is yet lost, since honey-gathering is at present quite at a stand. When warm weather returns your bees may possibly take heart and set to work in right earnest. The queen is certainly not dead. In driving bees, the queen (as well as the bees themselves), is so frightened by the continued rapping that she forsakes her own well-furnished but inverted dwelling, and runs for refuge into the empty one which is temporarily placed over it. If you peruse the very lucid and full description of the whole process which appeared in No. 139, we think you can scarcely fail clearly to understand it; and you may, if you please, transfer your bees to a frame hive in the manner described in page 319 of our present volume.

Bees Destroying Drone Brood (*An Isle of Wight Subscriber*).—This wholesale destruction of drone brood is owing to the recent unfavourable change in the weather, which probably became perceptible to the bees a day or two before you noticed it. The inhabitants of your Nutt's hive, which is doubtless made of wood, may also be on this account more susceptible to changes of temperature than those of the other hives. This reply is applicable to the case of "G. H.," but who, in addition, says that the bees are killing the adult drones.

From observations taken near London during the last forty years, the average day temperature of the week is 68.9°; and its night temperature 49.7°. The greatest heat was 85°, on the 3rd, 1846; and the lowest cold 32°, on the 31st, 1857. The greatest fall of rain was 0.90 inch.

ISOLATED PLANTS IN FLOWER GARDENS.

I CANNOT tell whether or no any great changes have been developing since last autumn in the pits and propagating-houses of the "upper ten" of the gardening world, but I am inclined to believe that there has already set in a decided reaction favourable to the introduction of softer and more graceful features into our system of flower-garden decoration.

For several years rumours of dissatisfaction have been afloat with regard to our present style, some of them faint and half-regretful, like the first indications of the breaking up of an old love, others degenerating into sarcasm as to the greater cheapness and adaptability of red lead, yellow ochre, and various pigments, for the purpose of colouring our beds; then come the epithets "Dutch formality," "Chineseism," "patchwork," &c., with which we are now so familiar, all indicating that the taste for the geometrical arrangement of great expanses of mere colour is on the wane. This, though not to be wondered at, is yet cause for regret; for although masses of hard unbending colour are not pleasant to look at, be they produced by what they may, yet when relieved, as they always are in gardens, by more or less of green foliage, and when in the arrangement of the colours due respect is paid to the few but important laws of harmony and contrast, then a well-designed geometrical flower garden, even though wanting in individual forms of gracefulness, will still be "a thing of beauty and a joy," if not "for ever," at least for four months or more in the year.

The adoption of fine-foliaged plants in what is called the sub-tropical style is a great move in the right direction, but having had no experience in the matter, I am, in consequence, totally unfit to say anything about it; only this much must be obvious to every one—that in half the places throughout Scotland and the north of England it would be something very near akin to madness to plant out such subjects as Dracænas, Caladiums, Ferdinandas (how it would rejoice our cold northern hearts to be able to grow a Calabash!), most of the Cannas, and many of the larger-leaved varieties of the Castor-oil plant, not to mention many other plants even more fragile which were last season used with such effect in Battersea Park and elsewhere.

Much, however, may be done in taking away the somewhat wearisome tameness of our present system by the more extensive use of isolated specimens of hardier and commoner plants, care being exercised that these do not, either by their size or proximity, overpower the beds, and thus more than neutralise the effects they are intended to produce. For this purpose some of the larger ornamental Grasses are pre-eminently adapted, and not the least so is the old unfashionable Arundo donax versicolor, which in rich soils attains a considerable height. Arundo conspicua is also a very remarkable object on an open lawn; it is a recent introduction, and well worth growing. Erianthus Ravennæ, a most ornamental Grass with large plumes of pure white inflorescence, grows to the height of 4 or 5 feet. Then there is that prince of all the Grasses, Gynerium argenteum (the Pampas Grass), than which, when well grown in single plants, nothing can be more elegant; but if grown in a small flower garden where there is no very heavy background of trees or shrubs it should not be allowed to flower, as its mammoth spikes seem to dwarf everything in its neighbourhood.

The time-tried Humea is also of much value in this way, as it can endure a great amount of wind, if well secured to a neat tapering stake up to within a few inches of the top.

Coronilla glauca variegata, grown pyramid fashion in pots and plunged in any part that requires to be lighted up, has a very fine effect. It is one of the easiest of all plants to grow, and makes also a very neat edging for beds; I have several times used it as such in a small way.

Other two plants, very different from those last mentioned, yet having a grace of habit peculiarly their own, are the Agave americana and Yucca gloriosa, both so well known and much used that little need be said about them. The first may be grown to a considerable size in small pots, which are easily plunged to the rim in lawns, being careful to make the hole deep enough to admit of another smaller pot being inverted in the bottom as a safeguard against stagnant water and worms. The Yucca may also be made portable by being kept in large pots where annual re-arrangements are desirable, but succeeds best when planted out in any soil that is dry and deep. In winter the heart of the plant should be protected by tying up the outer leaves, a few Spruce branches being placed round them in very severe weather. Although Yucca gloriosa is the species most frequently met with, there are many other Yuccas worthy of a place in the flower garden, as Y. obliqua, acuminata, aloifolia, serrulata, draconis, superba, and several variegated varieties.

All who have grown greenhouse Fuchsias in a slovenly manner, and there are very few who have not done so at some time, must have noticed how easy it is to bring them into the form of standards, a little neglect at first and a little timely pinching afterwards are nearly all that is required to make handsome plants for our present purpose. The stronger-growing old dark sorts do best, but some of the light are quite robust enough; for instance, Pearl of England and Venus de Medici. Unfortunately all of them are easily damaged by wind, so that for places entirely exposed to the west and south they are not very well adapted. I once tried a pair of them on wire umbrella trellises, but could not compliment myself on their appearance.

The plants I have named, it will be seen, are all of secondary importance in themselves, but fitted by elegance of form to remove to some extent that rather stiff appearance so much complained of. Some people say that at the

present day a want need only be felt and expressed to be in a very short time supplied; so I would hope that some day soon our nurserymen will put their catalogues through a process of expurgation, and clear a few pages for the reception of a list of plants as ornamental in form and foliage as those used in the London Parks last year, but requiring something a little less expensive than a stove for their winter quarters.—Ayrshire Gardener.

THE GARDEN OF THE PARIS UNIVERSAL EXHIBITION.

That portion of the park surrounding the Exhibition building which has been assigned as a garden for the display of objects connected with horticulture, lies adjacent to and parallel with the École Militaire. The visitor, therefore, who arrives by the bridge of Jena and enters thus by the Grand Avenue into the building, has to traverse its entire length in the same straight line until he finds himself in the park beyond. Passing through some sections on his left, devoted to Flanders and Brabant, he speedily reaches the garden itself, which is enclosed by iron railings of various patterns. Here he will have to pay an extra half franc, which covers all other expenses in this part.

To obtain a general view of the whole garden many ascend the artificial mound in the central portion, on which a handsome iron and glass structure, of great height and with curved outlines, has been raised. This is styled the "Serre Monumentale," and its exterior is efficiently covered with blinds composed of thin round strips of wood of the thickness of a quill, painted in alternate stripes of dull green and white, and which effectually exclude the sun's rays. The interior is as yet unfinished; a fantastic portico will serve for many purposes in the future. It is difficult, however, to imagine the practical purposes which this really handsome house could serve. It may, however, be an advertisement for the constructor. There have been few plants within it, and, with the exception of some fine pyramidal Azaleas, shown by Messrs. Veitch, nothing which the other houses could not have held is exhibited there. A good general idea of the plan and of the effect of the whole scene is obtained from this point of view. With a true conception of the nature of their object our neighbours laboured to raise here a central semicircular mound which dominates the ground. As this is the old review ground of the Paris garrison, it may again serve for some military purpose. An artificial valley is thus formed, and the ground, rising gradually towards the arc of the semicircle, forms an agreeable slope all round. This has been planted with large trees; and these, now in leaf, mask the buildings in the streets, and concentrate the effect within its sphere. Considering that the ground (the Champ de Mars), was a dead level, what has been effected merits the warmest praise, and is a decided addition to the Exhibition.

In front of the Serre Monumentale spreads the "lac," of course of no great size, and other pools diverging on each hand continue the effect of the water. They are small—too small in fact, and the imitation rustic bridges, which were needed for communication, might have been more pretending. Gay flower-beds are formed in the thriving turf, but the French do not excel in the art of bedding-out. Indeed, these beds, labelled and placed under painted canvas pavilions, are but so many advertisements of French seedsmen, and are meagre and ineffective in themselves. In this portion one misses the English taste, which has done so much in geometrical flower-beds. The depreciators of bedding-out, as now practised, could not, however, like these mixed beds.

The great attractions in the garden are the two aquaria. That for salt water is unfinished; but the fresh-water aquarium is perfect, and much frequented. A waterfall passes over the summit of the grotto under which the aquarium is constructed. The next attraction is the pavilion, in which some magnificent band plays each afternoon. Behind the pavilion is the section reserved for the fruit trees, and near it is the stove wherein were the plants with which Messrs. Linden and Veitch contended for floral honours. On the other side of the pavilion is a restaurant, evidently an important "*concession*." It displays the Imperial banner, whose field, thickly strewn with the Imperial emblem, carries a golden eagle in the centre. Below, the incessant stream of people proves how fashionable the garden is likely to be. As with us, music, no doubt, contributes largely to its attractions, and the strains of the band of the Guides now invite a descent from the Serre Monumentale towards the pavilion. The slopes of the ground are well clothed with healthy young trees and shrubs, all carefully labelled, and worthy of examination. Many old favourites and some new plants are here luxuriating in the rich black soil. Lower down, and at the base of the mound, are the French horticultural implements. Some of these are by no means unworthy of examination, and are commendable for cheapness.

Following the crowd (no bad course after all), we arrive at the fresh-water aquarium, constructed with immense labour and on a large scale. It is divided into compartments in the artificial grotto, and the fishes, among which are descendants of the famed carp from Fontainebleau, which were originally placed there by Francis I., are seen floating at the level of the spectator's head. Other varieties are visible in the remaining compartments. This aquarium is a very great source of pleasure to the Parisians. Little can be learnt, of course, even by repeated visits, of the habits of the fishes. This requires long observation, and what the salt-water aquarium can teach is to us, dwellers on the seashore and fishermen, a marvel! The aquaria, however, serve their purpose well, and possibly they will create a taste for such instructive pursuits, and thus the object in view will be realised. In this sense the whole Exhibition is wonderfully interesting, and is certainly well calculated to succeed. The grotto itself is a beautiful artificial cave, and it would be a pity not to preserve it. One can imagine that rare effects could be produced here by moonlight, or by coloured illuminations. On the summit is a large burnished globe, wherein, by shifting one's ground, a view of the whole garden is gradually obtained, including a portrait of the spectator himself, with his head curiously and somewhat alarmingly foreshortened, as we see in caricatures.

All this time the echoes of the band of the Guides have been luring our not-unwilling steps toward the orchestral pavilion, and from here, too, an artist would select a stand-point to photograph or sketch (were it allowed), the scene. Under the shade are many of those very convenient iron chairs, so common in Paris, filled with listeners. Crowds appear and are lost in the windings of the slopes blooming with Rhododendrons. They wind past the miniature lakes, cross the tiny bridges, and ascend laughing to the seats near us. Strangely enough, not a shadow of any national costume is to be seen. You may hear close to you Russian, Swedish, Roumanian, or any other language (far more readily recognised than many think), but the utterers themselves, men or women, are unrecognisable as to dress—not that they are aristocrats; far from this, the mass appears to be of the middle class, or even of a lower grade. After a time the eye distinguishes national peculiarities, of feature especially; but, at first sight, what difference is there between one foreigner and another as to dress? Are they not all equally strange to, and all unlike us in this respect? There is one great delusion which this international meeting dissipates, and that is, that educated people differ essentially wherever they may be. National costumes are fast disappearing. The figures representing such in the building, though of high finish, serve only to excite the hilarity of the crowd. You pay two sous for your chair, and repeat this at every move, and it is wonderful how often this is done. From here, close to the Empress's Pavilion—another "*concession*," and covered with the names of the tradesmen selected—the view is charming and characteristic. One regrets that the garden was not of larger extent, so artistically has it been laid out, and so fashionable has it become. There are here few of the hybrid kiosques, or sham mosques, which abound in the park, and the eye finds repose in the fresh green of the turf and the bloom of the flowers around, while the distant hum of Paris reminds the visitor that he can, by a few yards of movement, regain the crowded streets, or return to the bewildering riches of the Great Show.

The police of the garden is paternally administered by members of the old Garde Municipale. Very polite are they, and strangers should always consult them or the sergents de ville when in any doubt—not, however, if they really wish to approach any of the crowned heads who visit the Exhibition, unless it be to do exactly the reverse of what they advise you to do.

Those who expect to see a good display of fruit and vegetables will be disappointed, unless autumn greatly change the character of the Show. As usual, our neighbours trust wholly to their fine climate, and neglect artificial aids for maturing fruits. The results are visible in nine mean and small Peaches and six Nectarines, shown about the middle of this month. Some Calville Apples and Uvedale's St. Germain Pears made up the rest.

What the autumn may produce will, no doubt, be much superior, though here, as in London, there is much the same indifference on the part of cultivators. Intending English exhibitors might, therefore, reflect with advantage before they be at the pains of forwarding any fruits. Few natives exhibit, and very few spectators visit the sheds devoted to these classes, which are readily discovered by those who wish it.

Taken as a whole, what is exhibited in the garden represents in no adequate measure the state of horticultural progress in France. With the exception of the tools and implements there are no evidences of other horticultural materials worthy of note. Ground vineries we find, together with Saynor's splendid pruning instruments, in the English Agricultural Annexe; but these seem not to attract the natives. In fact, it must be said our neighbours think their own ideas equal to most emergencies, and in the case of gardening not the least of all.

Visitors having time should go to the City of Paris establishment at La Muette, Passy, which I went over with much satisfaction. From here the flower-beds in the park of Monceaux and other parts are supplied, and the glass houses of the Exhibition garden are finally to be re-erected at La Muette. The flower market, near the Madeleine, is also really worth a passing visit, and furnishes some hints in the arrangement of bouquets.—T. C. Bréhaut.

SPRING FLOWERS.

One receives so much interesting information in the pages of this Journal from the writings of amateurs, that, imperfect in exact knowledge as such contributions generally are, I feel bound to add what I can to the general stock.

I have been trying a spring garden this year, according to the fashion, and some memoranda, made for my own use, may be of service to others.

In the first place, is it worth the trouble? The effect is slight compared with the gorgeous colours of summer, and the beauty fleeting. On the other hand, there is a delicacy of their own in the hues of spring; and the little care and labour involved in comparison with what is needed for a summer garden, have made me determine never again to look for six months of the year upon rough brown beds of earth, which serve in their desolation to remind you more forcibly than anything else that summer is gone. If these naked beds are clothed with colour of any kind, so long as it be not that of coloured earths, a great deal is gained. Then the trouble is slight. To protect winter plants in the summer months does not require literally one-tenth of the labour, nor one-twentieth of the expense, necessary to keep summer plants through the winter. Some corner of the kitchen garden, rather shaded from the sun, will hold all the stock you require, and one touch or two at the right season (in these four words lies all the difficulty), will keep your laid-by winter dress in perfect order. The little attendance required must, however, be given to each plant at its proper season. The seed-sowing is not to be done all at once. It is provoking to find in November, instead of a sturdy little plant compact enough to bid defiance to the frost, a loose expanding creature, just beginning with a too-confiding tenderness to open its blossoms to the first blasts of winter. Then bulbs with withering leaves are uninteresting, and are apt to miss the one watering they require, or to be left in the ground a prey to mice and slugs. The patch of reserve garden, therefore, should not be altogether out of sight.

The best plants are those that bloom the earliest. Many annuals, such as Collinsia, &c., are very beautiful; but they trench upon the summer season, and make the gardener impatient to be rid of them even at their prime. In this respect Daisies and Pansies, both hardy, and both easily divided and easily moved, carry off the palm. One of the prettiest beds was a blue Pansy, obtained from Messrs. E. G. Henderson and Son, with a ring of Golden-leaved Daisy round it, and an outer ring of Crocus La Majesteuse; the Daisies 10 inches from the edge, that they may not be smothered by the Crocus leaves, and the whole bed raised much higher than in summer time to show-off the low-growing plants. The Pansies were in blossom before Christmas, and came into bloom again with the rapidity of an Alpine Gentian as soon as the snow melted, and their bright blue, now, it must be confessed, fading into a duller colour under hotter sunbeams, was a most pleasing contrast to the yellow leaves and crimson flowers of the Daisy.

Another striking Pansy is the Magpie, free blooming, but later than the other, and somewhat melancholy in effect; a French nurseryman would have named it Deuil d'un Prince. It requires a crimson Daisy round it. The yellow Pansy blooms nearly as early as the blue, and makes another good bed, with a ring of Aubrietia.

The Aubrietia likewise flowers early, and its mauve colours are well contrasted with a ring of white Daisies. When removed it shrivels up in the heat of summer, but revives with the autumn rains. A still greater favourite is Phlox verna, which forms a close carpet of delicate lilac, with the same white edging round it. Let me confess that I made the mistake of setting a crimson Daisy near it. How quickly one detects the mistake when the first flower opens. Its only fault is that in winter its foliage is brown and sere, and it is not so well fitted for a bed close under the eye. These beds six weeks ago were gay with Tulips, which went out of blossom before the Phlox opened. I have tried the same plan with Hyacinths, blooming them in beds of Silene, Forget-me-not, and Limnanthes, the leaves of which afforded an excellent foil to their flowers, and which are now hiding with their own bloom the leaves of the Hyacinths. Bulbs flourish in a dry soil so well that single Hyacinths bloom with us and increase year after year. The Silene, however, grows so tall as almost to smother the leaves, and I will not answer for their bloom next year. Not so the Forget-me-not. With this last, seedling yellow Alyssum makes an excellent contrast of exactly the same height, and exactly contemporaneous in bloom, only do not plant it where you look to a brighter field of Buttercups beyond it.

The three annuals above mentioned give little trouble, and will seed themselves if a few plants be put in a shrubbery. The green Fern-like leaves of the Limnanthes compensate for the lateness of its flowers. No manure should be dug in with annuals at the time of planting. Arabis variegata looks well in mid-winter; but all white flowers, even Hyacinths, are cold in spring.

The Anemone has failed more or less for two years; first, I believe because the tubers were kept for some months out of the ground; afterwards, because they were put in too soon, and the too vigorous plants were injured by the snow. Yellow Wallflower, sown early, makes a good ribbon-border with Magpie Pansy, which is rather tall, in front of it.

Every bed should have Crocus round it, which need not be removed in summer, as it will not be in the way of bedding plants. There should be some system in the colours, the yellow being kept in due subordination to the purples and the lighter colours. La Majesteuse, Sir John Franklin, Queen Victoria, and Sir Walter Scott are all good, and distinct.

By the means which I have described three successive periods of colour are insured—1st, the Crocus season; 2nd, that of Hyacinths and Tulips, with which Pansies and Daisies mingle; 3rd, the annuals.

I need scarcely add that I have been indebted to Mr. Fleming's little book on spring gardening, in which full directions for the management and propagation of spring plants may be found, for the pleasure I have received.—Wyesime.

VIOLA CORNUTA.

Some time ago there was an interesting controversy in the pages of the Journal, as to the respective merits of what were said to be two varieties of Viola cornuta. All parties, however, seemed to agree that the plant was one that would rank high in public estimation when it became sufficiently known and cultivated. It is not my purpose to reopen that controversy, which I imagine, after all, arose simply from the plants having been grown in different soils or circumstances, the effect of which, as we know, is often to give another tint to the colour of the flowers, or to cause some alteration in the character of plants. Be this as it may, I can bear testimony to the very gay appearance which the plant has at the present time, and if the continuance of its blooming be satisfactory, its merits as a bedding plant will be fully established.

Mr. Wills, through whose exertions this old-fashioned Viola has been restored to favour, was kind enough to send me some plants in the autumn of 1865. I kept them in a cold frame all the winter, and planted them out last spring, but unfortunately I happened to place them in a spot to which rabbits had access, and the result was, that the flowers were nipped off as produced, the plants escaping untouched. They have now acquired a breadth and compactness which could not well be excelled. Having recently planted many young Pinuses and other trees on the lawn in cultivated circular beds about 6 feet

in diameter, I put in a ring of Viola cornuta as an edging to some of these, as well as several other hardy plants remarkable for their compact growth, their foliage, or flowers. Arabis purpurea, and the dwarf variety of Alyssum saxatile, have been very ornamental, but are rather past their best, while Viola cornuta certainly promises to be more lasting, and at present (May 20th) is the gayest plant of its class. If it continue as it now is, too much cannot be said in its favour. Judging from its appearance, I should be inclined to think it will suit the north of England, or cool, moist situations better than dry, sunny ones, and I fear mildew will attack it in dry seasons, and on dry sandy or gravelly soils. This, however, I only put forth as an opinion, and shall be glad if my anticipation prove erroneous. I have no doubt that the merits of the plant will be fully tried this season, in widely different situations.—J. Robson.

LILAC-TIDE.

By such a name I designate one little period of the year, a short period, for the Lilac soon sheds its beautiful flowers; soon are they faded by the sun, then embrowned by it, and at length they hang withered bunches on the trees.

But, although Lilac-tide is a very brief season—a mere parenthesis in the year—still, it is a most beautiful period, beautiful in rich possession, and beautiful in richer promise.

Take a few other periods. There is hay-time to wit; but after the hay is gathered the landscape is injured; not the bright green of Nature meets the eye, but the yellow green of art, for where the scythe has cut the luxuriant vegetation, there the tint has faded down to paleness, besides a considerable portion of the summer is gone with the hay.

Or, take harvest-time—man's rejoicing time, fields of corn ripe and ready, and rustling for the reaper's hand. As says Bloomfield—

> "A glorious harvest fills our eager sight,
> Half shocked, half waving in a flood of light."

But soon the fields will be cleared, and then they will lie naked and void, and we shall feel that another season is far on the wane, another milestone of time in sight, and soon to be reached and passed.

But, in Lilac-tide all is different; it is the beginning of the season's beauty, its youth, its hopeful youth; chilliness is gone, genial warmth is come, but no thought of decline mars our enjoyment by overshadowing the present; the birds are pealing forth their notes, warmed, but not hushed as presently they will be, by the heat, while the rooks are filling the air at intervals with their musical clangour.

As I sit writing with breeze and sound coming to me through the opened window, there lies before me a bunch of Lilacs of both colours, placed there by a child's hand. (Whose pleasure was the greater—the giver's or receiver's?) The white Lilac—so white—those unopened flower-buds, not pearly white, for no pearl ever equalled their whiteness; what a contrast to the broad green leaves! The Lilac leaf has a colour all its own, a dark yet clear and even greenness throughout. Then, there is the other Lilac—the Lilac proper—the commoner and stronger-growing variety, it has a colour in nature to itself, giving a name to a certain hue. But although cut Lilac is pleasing to the eye, yet commend me to the flowers on the tree. Horace Walpole was wont to hurry down from London to Strawberry Hill to enjoy Lilac-tide, and verily if I must pass the whole year

> In populous city pent,"

still let there be a reservation as to Lilac-tide, for I must be in the country then.

Surely, when Londoners, if not Londoners born, see the draught horses come into town with branches of blooming Lilac nodding and bowing on their heads, they must long and pine, and "weary," as the Scotch say, for the pure, pure country air, where the Lilac trees are standing in unsmoked beauty. And yet, happy London, with its pretty suburbs improved by the gardening art of centuries, beauty, country beauty, is close to you. Go out westward, weary citizen, and the country will soon meet you—pretty villas, with bright green lawns, trim flower-beds, and Lilac trees all in bloom. Go further, and pause at the gates of many a country house overlooking the broad Thames, and see how art and nature together have produced a glorious English garden.

But, it is not near London, no nor in Wilts, nor even near the fair city of the west, beautiful Bath, that you can fully enjoy Lilac-tide. You must go further west, to warm, green Devon, for a perfect spring. There the air is soft, and "winter lingers not in the lap of spring." There you may wander out on early summer evenings, yea, even sit out as you dare not in any other part of England. There the grass is greener, and the leaves more fully out in April than in any other county, and there the Lilacs bloom in fuller, richer beauty than in any other part of our island home.

Miss Eden in her interesting book on India, "Up the Country," tells us we enjoy nature most, but remember art the longest; that of a day spent in the country, even in its fullest beauty, the mind retains nothing distinct, that the beauty of a landscape leaves but a haze on the memory, while on the contrary a fine painting remains for ever engraven in all clearness on the mind. We remember, too, the day, the hour, the attendant circumstances, and the picture itself stands out before us bright and clear, and as we saw it once we see it always. I doubt this. There are days and scenes which never fade from our memories, but are photographed on the brain, and precious memories they are to us, and sure brighteners of after-life. I can close my eyes and see the flower, or the landscape, as clearly as I can that Carlo Dolci which I saw years ago in its green-silk-hung little room at Burleigh, and of both nature and art I can say—

> "Those beauteous forms,
> Through a long absence, have not been to me
> As is a landscape to a blind man's eye.
> But oft, in lonely rooms, and 'mid the din
> Of towns and cities, I have owed to them,
> In hours of weariness, sensations sweet,
> Felt in the blood, and felt along the heart."

But, to return to Devonshire, as the very land of spring floral beauty. Not only in South Devon, where the Myrtle blooms in the open air, but in North Devon (nearly as lovely, and with a fresher air, where many can enjoy life who are almost stifled by the soft air of the south), is springtide to be seen in full perfection. Perhaps some of my readers know Bideford, a famous port in the old Armada days, and although it is a humble place now as to shipping, yet it is a bright, dry, pleasant-looking town, as the old song says—

> "Bideford is a pretty place, it smiles where it stands."

Well, after watching, some years ago, from its many-arched bridge the catching of a fine salmon, I, house-hunting for a friend, ascended a hill near, where a residence was to be let, and found an old—scarce mansion, scarce cottage—but something between the two. A heavy shower had just fallen as I entered the gate, a shower which had pelted the ground and pattered on the new green leaves, and the grateful earth was sending up an incense-like smell, and as to the flowers—

> "Their breath was mixed with fresh odours, sent
> From the turf, like the voice and the instrument."

Proceeding, I beheld a wavy line of Lilac trees in full bloom; a wavy line of Lilac trees hanging over the approach. Each tree was shaking off in the sunshine the recently-fallen shower-drops. Such a show of Devon-blossoming Lilac, the like of which I had never seen before.

> "Lilacs various in array, now white, now sanguine."

A group of laughing girls had taken refuge from the storm, in the porch of this old house, and were now essaying to escape on tiptoe along the gravel path.

And when Lilac-tide comes round each year, I think of that scene, the clean west country town, the bright clear bay, the Bristol Channel glittering in the sun, and Lundy Island standing up above the sea as an oval-shaped jewel stands from a ring; it looked in the pure atmosphere like some fairy land, some home for beings, perhaps little children, too pure and innocent for mixing with the throng in this tainted world; and, then, last of all—and longest of all—I think of the blooming Lilacs, bending their beautiful heads, wet and perfumed, in the sunshine.—Wiltshire Rector.

THE APPLE CROP OF 1867.

From information which has reached me from various parts of Kent and Sussex, there appears to be an apprehension of a great falling off in the Apple crop of the ensuing autumn, owing to the late severe winter, which has caused so many abortive blooms, and this idea will be strengthened by the occurrence of the severe frosts and biting winds of the past fortnight, which have made havoc of and sadly disfigured the young growth of nearly everything exposed to them, as well as of the Apple bloom. On examination, however, of the orchard under my

own charge and of those in the immediate neighbourhood, I do not apprehend such serious consequences as the first appearance might indicate. In the first place, there has been a profusion of healthy expanded bloom on both old and young trees of early and late varieties, which are set very freely, and if one-sixth of the fruit swell-off there will be a good crop of kitchen sorts, and an average one of dessert kinds.

How fare others in different localities? I registered 5° of frost on the morning of the 15th, and 3° on the 16th inst. Pears, Cherries, and Plums promise abundantly.—Thomas Record, *Hawkhurst, Kent.*

ROYAL HORTICULTURAL SOCIETY.

Floral Committee.—*May 21st.*—Although the Meeting this day was specially dedicated to the examination of variegated Zonal Pelargoniums, several plants of great beauty and interest were exhibited. The following awards were made:—Messrs. Veitch exhibited a large collection of new plants, of which Dichorisandra mosaica, a beautiful-foliaged plant, had a first-class certificate, Dichorisandra undata one of the second-class, Adiantum variety of concinnum a first-class certificate, Dracæna regina a first-class certificate. Dendrobium MacCarthiæ and D. Parishii had both been awarded first-class certificates two years ago. A special certificate was awarded for a beautifully-grown specimen of Anthurium Scherzerianum with the largest scarlet spathee yet seen. Messrs. Veitch also exhibited Echites rubro-venosa, Taxus hibernica fastigiata, an Aralia, and a new bedding plant, Irva sanguinolenta, with dark reddish purple foliage. Mr. Bull exhibited several new plants, of which Anthurium regale had a first-class certificate, Zamia villosa a first-class certificate, Dichorisandra mosaica a first-class certificate, and D. undata a second-class certificate. Seedling Zonal Pelargonium Valiant, and a basket of well-arranged Zonal Pelargoniums in small pots were also shown by the same exhibitor. Messrs. Backhouse sent an Orchid rarely seen in flower, Oncidium nubigenum. Mr. Williams, Holloway, sent small plants of Athyrium Filix-fœmina plumosum grandiflorum, an Adiantum, a seedling from Farleyense, and Gymnogramma Steltzneriana, with very little colour on the back of the frond; probably these plants were too young to develope their beauty.

Mr. Standish, Ascot, received a first-class certificate for Retinospora filifera; and Mr. Kinghorn a first-class for a very lovely Azalea called Lizzy, with pure white flowers with rosy purple flakes. The outline and substance of the flower and petals were perfect. This will be found one of the best in the section of the white Azaleas. He also sent Azalea Conspicua, bright rose, but no advance on others. Messrs. Osborn, Fulham, sent a collection of cut flowers, which in the hurry of the meeting were overlooked, and would have had a special certificate; also a singular form of Lomaria gibba var. Belli, raised from the spores of L. gibba: this variety received a first-class certificate in 1865. From the same firm came likewise a dwarf-growing plant of Osmunda regalis, to be named by Mr. Moore, and which received a first-class certificate; and Viola pedata, a very pretty plant with divided foliage. Mr. Green, gardener to W. Wilson Saunders, Esq., received a special certificate for a collection of plants; and W. W. Buller, Esq., a similar award for a collection of Orchids, consisting of beautiful Cattleyas and Dendrobiums. Messrs. Low, Clapton, had a special certificate for a collection of Cattleya citrina with exquisitely perfumed flowers, much resembling in size and colour the Daffodil. Mr. William Paul had a first-class certificate for Ulmus aurea, a very promising yellow-foliaged Elm. Messrs. E. G. Henderson sent Epigynium acuminatum, a very singular plant, the deep scarlet flowers being produced on the stem; it received a second-class certificate; also Ulmus aurea, which had a first-class certificate. Mr. Turner, Slough, contributed several fine seedling Pelargoniums of the large-flowering kinds. Example, a very beautiful flower, had a first-class certificate. Victor also received a first-class certificate; and Heirloom one of the second class. The others were Patrician and Leotard, and Fanny Geir and Excelsior, two Fancies.

We must now as well as we can give some account of the Tricolor Zonal Pelargoniums, or, as it has been suggested, Versicolor or Variegated Zonals. In this large collection from all parts of the kingdom, we need not be surprised that there was a great similarity, and hence the difficulty of making a selection of the best and most distinct. It would not be correct to say that they were all good, but a very great many were so. Mr. Turner received a first-class certificate for seedling Zonal Mrs. Turner; Messrs. E. G. Henderson had a first-class certificate for Sunshine; Messrs. Downie, Laird, & Laing a similar award for Nosegay Pelargoniums Countess of Rosslyn and Emmeline. Mr. W. Paul received first-class certificates for Nosegay Lilacinum and Versicolor Zonal Red Admiral. Mr. Wells had for Her Majesty, with a dark broad zone on a yellow ground, a first-class certificate, and a like award for Beauty of Ribblesdale. Mr. John Mann, Brentwood, exhibited a seedling Zonal, Lord Derby, the finest and largest scarlet yet produced, and having green foliage and a dark zone; it was awarded a first-class certificate; and Christabel, with bright rosy flowers received one of the second class. Mr. Wheatley, gardener to the Rev. R. Clive, sent a seedling Ivy-leaved Pelargonium Mrs. Clive, the leaves with pink margins, a very distinct variety, for which a first-class certificate was awarded. From Mr. Grieve came Victoria Regina, the brightest and most highly coloured Variegated Zonal yet seen; a first-class certificate was awarded. Messrs. F. & A. Smith, Dulwich, sent Magnificent—first-class certificate; Resplendent—first-class certificate; and Jetty Lacey—first-class certificate; Mr. Groom, Ipswich, Lord Stanley—first-class; Messrs. Saltmarsh, Sunrise—first-class, and Crown Jewel—first-class.

Medals were awarded to the exhibitors of collections as follows:—

Silver Flora to Messrs. E. G. Henderson, who exhibited their finest specimens of the best varieties in cultivation; the bright and vivid colouring of some of the varieties, such as Lady Cullum, Lucy Grieve, Sophia Cusack, Sophia Dumaresque, Italia Unita, &c., cannot be surpassed. The examples illustrating the first break into colour, the gradual process before the colour and character become fixed, the prognostics of a diseased or healthy growth, were very interesting and well defined by Messrs. Henderson.

Silver Flora to Mr. Wills. This collection, so well represented by the peculiar strain of which Beauty of Oulton is a type, was very extensive and superb.

Silver Flora to Mr. Grieve. This father of Tricolor Zonals, as he may very properly be styled, exhibited some extremely fine varieties, too many, indeed, for their names to be taken down as we could have desired to have done. The crowning work of skilful cross-breeding was well and nobly exemplified in his magnificent seedling Victoria Regina, which certainly stands the premier among Variegated Zonals.

Silver Flora to Messrs. Carter & Co. In this collection were some of the finest Tricolor Zonals yet seen; but as the rules of the Floral Committee forbid awards to be made to seedlings, several of these in this as well as in others were passed. There were some first-class varieties among them; when their character as to colour and habit shall have been fixed they will most assuredly stand high in the estimation of the admirers of these plants.

Silver Knightian Medal to Messrs. Smith, Dulwich. The collection sent by this firm was very excellent, and although the plants had suffered severely from the knife, and had not their usual fine and healthy foliage, their peculiar style and colouring were greatly admired, as the certificates awarded will testify.

Silver Knightian to Messrs. Garaway. Many beautiful varieties were to be found in this collection. Mrs. Allen was specially noticed for its great beauty, both in the colour and form of the leaf.

Silver Knightian to Messrs. Saltmarsh. A curious sport of a Fancy Pelargonium was exhibited in this collection, the white margin of the leaf being well and distinctly defined. Sunrise and Crown Jewel were certainly gems.

Bronze Flora to Mr. Groom. Lord Stanley is a most beautiful variety, rich in colour and marking. There were several other excellent kinds.

Bronze Flora to Messrs. Windebank & Kingsbury. This collection contained small plants, many of them yearlings, and of great promise.

Bronze Flora to Mons. Langlois, St. Heliers, Jersey, who exhibited some beautiful seedlings, but not sufficiently distinct from others in cultivation.

Several other collections were sent by Messrs. Chater, Watson, J. Aldred, Perkins, Wood & Ingram, and Maule & Sons, in each of which plants of great merit were to be seen.

The care taken to give the pedigree of seedlings reflects great credit upon the exhibitors, and will, without doubt, prove very useful to those who are commencing the interesting occupation of cross-breeding. The only regret that can be expressed on this occasion is that there was not more time for examining the plants. However, the Meeting was a great success, the forerunner, we trust, of another display of the Versicolors. Public thanks are due and will be voted *nem. con.* to those exhibitors who so kindly and liberally supported the Meeting. Such a sight had never been seen before.

Weekly Show, *May 25th.*—Prizes were offered for collections of Fancy Pelargoniums (Nurserymen); for miscellaneous plants (open); for Cape Heaths (open); for cut flowers arranged in a basket (open); and for the best exhibition of Vegetables (open). The cold weather of Saturday last prevented all but two exhibitors sending plants. A first prize was awarded to Messrs. Lucking Brothers, Bayswater, for a collection of twelve miscellaneous plants; and Mr. Morgan, Ball's Park, Hertford, gained a first prize for cut flowers in a basket. From the Society's Garden, Chiswick, an interesting collection of plants was exhibited, consisting of pot Roses, Calceolarias, Petunias, variegated Sedum, Gloxinias, Schizanthus, &c.

TRICOLOR PELARGONIUMS.

I am concerned that my remarks appear to have been misunderstood. If Mr. Grieve will give those remarks a second perusal, he will find that I carefully avoided any comparison of Mr. Basket's Rainbow with Mrs. Pollock as a Tricolor Pelargonium. It is in many points essentially different and inferior; also all the zone, brilliant as it is, is not permanent as summer advances; and, as I stated, I grow it for its noble truss of bloom only. As the parent of Burning Bush and other well-known handsome plants, I thought the fact of its early existence deserved notice. Again, Burning Bush as an earlier

production was the forerunner of Italia Unita, but I by no means asserted it to be the progenitor of that beautiful plant. —M., *Deptford.*

CRYSTAL PALACE SHOW.—May 25th.

It is certainly a fortunate circumstance that the dates fixed for the great horticultural London Shows are unusually late this season, for even the earliest, the Crystal Palace Show, held on Saturday last, not a month from midsummer, took place on a day as chilly and ungenial as any in this exceptionally cold season. There was, notwithstanding, a remarkably large attendance of visitors, of ladies especially, so much so that locomotion about the middle of the afternoon was a work of no small difficulty. The display, however, was well worthy of the inspection of the numerous company which it attracted, and though there was a slight falling off in some respects, this was amply compensated for in others, and as a whole it may be pronounced quite qual to its predecessors.

Stove and Greenhouse plants, as in former years, constituted the most important feature, and the collections shewn were numerous, and several of them of great excellence. Mr. T. Baines, gardener to H. Micholls, Esq., Summerfield, Bowden, Manchester, took the lead in the class for sixteen with an admirable collection, in which there were Ixora aurantiaca and coccinea, the latter with some remarkably fine heads of bloom; one of the finest specimens of Acrophyllum venosum ever seen, a very large and finely-bloomed plant of Genetyllis tulipifera, the showy crimsen and white Clerodendron Thomsonæ, Dipladenia crassinoda, Boronia serrulata, Eriostemon densiflorum, Franciscea confertiflora, Aphelexis, Azaleas, Heaths, and a fine plant of Epaeris Eclipse. Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood, came second with, among others, a fine specimen of Erica Cavendishii, E. ventricosa magnifica, Erioste mons, Pimelea decussata, Genetyllis fuchsioides, Dracophyllum gracile, a fine specimen of Tetratheca ericæfolia, and Allamandas, the last quite equal to any exhibited, but far from so fine as in former years. Mr. D. Donald, gardener to J. G. Barclay, Esq., Leyton, who was third, had a very good Stephanotis floribunda, the blue-flowered Sollya linearis, a fine Clerodendron Thomsonæ, Rhynchospermum jasminoides, and the deep yellow-flowered Cassia corymbosa. Other collections in the same class were furnished by Mr. Kemp, gardener to Earl Percy, Albury Park; Mr. Wheeler, gardener to J. Philpott, Esq., Stamford Hill; and Mr. Coles, gardener to R. H. Page Henderson, Esq., Beckenham, and comprised besides plants already named, examples of Hoya Paxtoni, Posoqueria longiflora, with long-tubed white flowers, Coleonema rubra, Polygalas, Chorozemas, Plerema elegans, the blue-flowered Leschenaultia biloba major, and Statice profusa.

In the class for ten, Mr. Peed was first, and Mr. Wilkie, Oak Lodge, Kensington, second; the latter having a fine specimen of Medinilla magnifica, and Clerodendron Balfourii, which, however, as shown was not more effective than the species Thomsonæ, of which it is a variety. The third prize went to Mr. Kemp, who had a large specimen of Coleonema rubra, and Erica Westphalingia in fine bloom. From Mr. Wheeler, gardener to Sir F Goldsmid, Bart., M.P., came the small yellow-flowered Dillwynia floribunda, a very old plant but not often exhibited, though useful in a New Holland-house.

In the corresponding class for Nurserymen, Messrs. Lee, of Hammersmith, took the first prize with a very fine specimen of Genetyllis tulipifera and Ixora coccinea, Aphelexis macrantha purpurea splendid in colour, and an excellent specimen as well, Stephanotis floribunda, Franciscea confertiflora, Azaleas in fine bloom, and Heaths. Mr. Rhodes was second with specimens of Heaths, Aphelexis, and Genetyllis tulipifera and fuchsioides, the latter very bright in colour. In the collection of Mrs. Glendinning & Sons, which was third, was Stephanotis floribunda in fine bloom; and in that of Mr. Williams, which took the next place, Bougainvillæa glabra.

For six plants, Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, was first; Mr. C. Smith, gardener to A. Anderson, Esq., Norwood, second; and Mr. Wheeler, Stamford Hill, third. The first two had good examples of Dracophyllum gracile; and Mr. Ward had also Phœnocoma prolifera Barnesii, a good specimen, but not sufficiently advanced in bloom to prove effective.

Mixed collections of fine-foliaged and flowering plants were on the whole excellent, especially those from Messrs. Lee, Williams, and Baines, who took the three principal prizes. The fine-foliaged plants consisted of fine specimens of Theophrasta imperialis, Rhopalas, Cordyline in divisa, Alocasia metallica, Sphærogyne latifolia, Pandanuses, tree Ferns, Palms, Crotons, variegated Aloe-leaved Yucca, and Marantas. Mr. Baines had a noble specimen of Dicksonia antarctica, with a thick trunk, Gleichenia speluncæ and flabellata, large and in beautiful condition, and Sarracenia purpurea with its green and purple-veined pitchers, remarkably fine. Among the flowering plants were Ixoras, Clerodendron fallax, Aphelexids, Genetyllis tulipifera, Stephanotis floribunda, Medinilla magnifica, Rhyncospermum jasminoides, Azaleas, Heaths, Eriostemons, and the white-bracted Mussænda frondosa, &c.

Of Heaths there was a good display of well-grown plants in good bloom, but not essentially differing from exhibitions of previous years. The principal prizes were taken by Messrs. Rhodes, Baxendine, Peed, J. Wheeler, Wilkie, Ward, and J. & C. Lee.

Azaleas were not equal to those exhibited earlier in the season, and many of them were past their best. There were, however, well-bloomed specimens of Extrani, Coronata, Holfordi, Perryana, Iveryana, Chelsoni, Optima, Trotteriana, Criterion, Triumphans, Gledstanesi formosa, Barclayana, and the effective yellow-flowered Sinensis. The awards were:—For eight (Nurserymen): first, Mrs. Glendinning & Sons; second, Mr. C. Turner. (Amateurs): first, Mr. Penny; second, Mr. G. Wheeler, gardener to Sir F. Goldsmid, Bart., M.P.; third, Mr. W. Gell, gardener to Mrs. Beaufoy, South Lambeth. For six (Nurserymen): prize, Messrs. J. & C. Lee. (Amateurs): first, Mr. S. M. Carson, gardener to W. R. G. Farmer, Esq., Cheam; second, Mr. Wilkie; third, Mr. C. Smith, Norwood.

Orchids, most probably owing to the coldnesa of the weather, were not shown so numerously as usual. The best collection of twenty came from Mr. Penny, gardener to H. Gibbs, Esq., Regent's Park, and contained Odontoglossum Phalænopsis with five beautiful blooms, Phalænopsis grandiflora with three good spikes, a good Cattleya Skinneri, Dendrobium nobile, the yellow and brown Oncidium sarcodes, Saccolabium carvifolium, Aërides, Lælia purpurata in fine bloom, L. cinnabarina, Vanda suavis, Cypripedium lævigatum with four blooms, and a fine specimen of C. barbatum superbum. Mr. Gedney, gardener to the Rev. W. Ellis, Hoddesdon, was second with Cattleya citrina having six fine blooms, Lælia cinnabarina, with four spikes of bright orange flowers, Oncidium ampliatum majus, Dendrobium tortile, Vanda cristata, Epipbora pubescens, with yellow and brown flowers, a South African species which has been known for thirty years, but is seldom exhibited; Chysis Limminghi, Oncidiums, Cattleya Mossiæ, Aërides, and Saccolabiums. In the class for ten, Mr. Williams, of Holloway, was first with Cypripedium Stonei with remarkably fine flowers unusually delicate in colour, Anguloa Clowesii, Cattleya Skinneri, Lælia elegans, Dendrobium nobile Wallichianum, &c. Messrs. Lee, who were second, had among others Dendrobium densiflorum and nobile, Odontoglossum citrosmum, with more colour than usual, and the yellow and brown Oncidium altissimum. In the collection of Mr. Young, gardener to W. H. Stone, Esq., Leigh Park, Havant, who was first for twelve, we noticed a fine spike of Phalænopsis Schilleriana, Cypripedium hirsutissimum, and Odontoglossum citrosmum.

New and rare plants (with the exception of florists' flowers, which are noticed in a separate report), were shown in considerable numbers by Messrs. Veitch and Mr. Bull, and less numerously by other exhibitors. Nearly all of them, however, have been noticed in recent reports. First-class certificates were awarded to Messrs. Veitch for the yellow-veined Sanchezia nobilis variegata, Dichorisanda mosaica, Maranta Veitchii, Dracæna regina, with creamy yellow variegation, and Areca crinita, a graceful Palm; second-class certificates for Lomaria ciliata, from New Caledonia, Retinospora plumosa, and Bignonia ornata. Mr. Bull had first-class certificates for Sanchezia nobilis variegata, Dichorisandra mosaica, Anæctochilus petola marmorea, Tillandsia argentea, and Zamia villosa; and certificates of the second class for Asplenium myriophyllum, Agave macracantha, Athyrium Goringianum pictum, and Maranta roseo-picta. The last two being likewise shown by Mr. Williams, a similar award was made to him for these, as also first-class certificates for Sanchezia nobilis variegata, and the golden-variegated New Zealand Flax. Mr. Carr, gardener to P L. Hinds, Esq., Byfleet, had a first-class certificate for a beautiful specimen of Adiantum Farleyense, a distinct and bold-looking Fern of recent introduction. A similar award was made to Messrs. Lee, who, as well as Messrs. Veitch, exhibited Areca crinita.

Among miscellaneous subjects, Mr. Baines had some remarkably fine Ferns, including Davallia bullata, of a beautiful glossy green, D. tenuifolia, Pteris cretica albo-lineata, P. scaberula, and a very large-trunked Dicksonia antarctica, with a pendulous head. The same exhibitor likewise contributed fine Sarracenias, and Mr. Gedney Nepenthes Rafflesiana. From Mrs. Glendinning & Sons came some pretty Anæctochils, and from Mr. Drewett, gardener to H. Turnbull, Esq., Rookery Down, some beautiful wreaths of Bougainvillæa spectabilis.

Nothing could, I think, display more strikingly the wonderful skill and successful culture of English horticulturists than the marvellous display at the Crystal Palace on Saturday, after a winter unexampled of late years for the duration of its severity, and a spring which almost seemed to be a renewal of winter, with changes of temperature during the present month which were enough to baffle all precautions. Yet never have I seen, and rarely has any one else seen, such a display at the Crystal Palace May Show. Orchids were weak; but the wonder was, not that they were so few, but that there were any, considering the danger of having them frosted, a calamity which befell a vanload of Azaleas only the other day on their way to a show. Azaleas were not quite so good as I have seen them, but the stove and greenhouse plants were magnificent; and the Pelargoniums and Roses everything that could be wished. It is of these that I wish to give a few notes: and first as to the queen of flowers. The two collections of ten exhibited by Mr. W. Paul and Mr. Charles Turner were truly magnificent, the fault of the latter being that they wanted a few more days, as many of the plants were not sufficiently in bloom. The first prize was taken by Mr. W. Paul with Juno, a magnificent plant; Charles Lawson, as it always is, very beautiful; Général Jacqueminot; Madame de St. Joseph (Tea); Souvenir d'un Ami (Tea), a beautiful plant; Madame Villermoz (Tea), very good; Senateur Vaisse; Lælia, or Louise Peyronny, a beautiful plant; President, and Paul Ricant. Mr. Turner's consisted of Anna Alexieff, Victor Verdier, fine; Souvenir d'un

Ami, Charles Lawson, Général Jacqueminot, a fine plant; Souvenir de la Malmaison, Maréchal Vaillant, lovely; Paul Perras, Madame Damaizin, and President. Messrs. Paul & Son were third; this collection contained a lovely plant of Maréchal Niel. In the class for twelve Roses in eight-inch pots Messrs. Paul & Son were first with nice young specimens of Princess Mary of Cambridge, Maurice Bernardin, Souvenir d'un Ami, &c. Mr. Charles Turner was second, and Mr. W. Paul third. Messrs. Paul & Son also exhibited some boxes of beautiful cut blooms, to which an extra prize was awarded; and around these as usual was gathered a regular bevy of delighted visitors, who conned with more acumen than they did most things the very beautiful blooms exhibited.

For the last two years Mr. Turner has not been quite up to the mark with Show Pelargoniums. He tried some experiments, I believe, and they certainly had not been very successful. He has now quite recovered his ground, and I have never seen more magnificent plants than those he exhibited on Saturday, and with which he easily gained the first prize. They were Desdemona, Rose Celestial, a plant which was perfection itself; Lilacinum, Royal Albert, a fine flower and very effective; Spotted Gem, very pretty; Mdlle. Patti, a lovely flower with a clear white throat; Pericles, Belle of the Ball, Fair Rosamond, Exhibitor, and Fairest of the Fair. Mr. Fraser was a good second with Celeste, a rich warm rose, a little crumpled in the petal; Sanspariel, Desdemona, Candidate, Empress Eugénie, Beacon, Regina Formosa, Pericles, Roseum, a beautifully bright flower, and James Lodge. Amongst Amateurs Mr. Nye, gardener to E. Foster, Esq., Clewer Manor, was first with Favourite, Mdlle. Patti, Royalty, Sir C. Campbell, Belle of the Ball, Rose Celestial, Patroness, Fair Rosamond, and Garibaldi. Fancy Pelargoniums were also very beautiful; more difficult to show well than the show varieties, their successful culture displays greater skill, and the plants exhibited really seemed the very acme of perfection. Mr. Turner was again first with Lady Craven, Ellen Beck, very pretty; Lucy, Delicatum, very fine; Roi des Fantaisies, and Undine, very fine. Mr. Fraser, who was second, had Clara Novelle, Undine, Delicatum, Ellen Beck, and Marionette. Amongst Amateurs Mr. Donald was first, and Mr. Weir, gardener to Mrs. Hodgson, second.

I can well understand the perplexity into which the Judges must have been cast at the Tricolor Pelargonium Exhibition on the 21st, by the sample from only three exhibitors on Saturday; but some limit must be made, and especially now, as so much is said and thought about them. The three exhibitors were Messrs. F. & A. Smith, of Dulwich, who had a large collection; Mr. Watson, of St. Albans; and Messrs. Carter, who had some boxes of three varieties and a plant of a new seedling, which, if it retain its character when propagated, will be, indeed, a gem—Prince of Wales. It is very large, and a noble-looking plant. Messrs. Smith obtained first-class certificates for Exquisite, Mr. Grieve, Resplendent, deep yellow edge, broad zone, carmine red with black, very fine; Jetty Lacy, really magnificent, bright golden yellow, chestnut red and black zone; Louise Smith, yellow margin, zone of red and black. Mr. Watson, of St. Albans, had first-class certificates for his two fine plants—Mrs. Dix and Miss Watson, and Messrs. Carter had one for Titania.

Among the Show Pelargoniums Mr. Wiggins obtained a first-class certificate for Hermit, a fine, large white flower, with deeply-marked upper petals, and L'Empereur, a fine warm rosy crimson flower, and a second-class certificate for Queen of Roses, beautiful in colour, though somewhat rough. Mr. Bull obtained a first-class certificate for Lobelia Rosy Gem, a very curious and distinct colour; Mr. Cunningham a first-class for L'Elegante, silver-edged Ivy leaf; and Mr. Bull had Silver Gem, in the same style, but better. Messrs. Downie and Co. received a first-class certificate for Emmeline, a rosy pink Nosegay.—D., *Deal.*

ROYAL BOTANIC SOCIETY'S SHOW.

The first of the great summer Shows of this Society was held yesterday, and was in every respect a charming display, for although many of the subjects had appeared at the Crystal Palace on the previous Saturday, the fresh green turf banks employed at the Regent's Park instead of stages, made the plants look fresher and more beautiful than ever. Stove and greenhouse plants were as usual numerously shown, and in excellent condition, and of Ferns and fine-foliaged plants Mr. Williams had very fine collections. Heaths, too, were well represented; and Pelargoniums, both Show and Fancy varieties, as exhibited by Messrs. Turner, Fraser, Nye, and Ward, were not only large but in profuse bloom. Roses from Messrs. W. Paul, Turner, Paul and Son, and others, were admirable, and contributed largely to the effect of the Exhibition. Among Orchids Cypripedium candatum, in a fine collection from Mr. Wilson, gardener to W. Marshall, Esq., Enfield, was the finest specimen of that singular and highly ornamental species which we remember having seen. Odontoglossum Bluntii had no less than eleven of its beautiful blossoms, the largest number with which it has as yet been shown, except by Mr. Anderson, of Meadow Bank, who exhibited it with twelve. Of new plants, Messrs. Veitch and Bull had each interesting collections. Fruit was not invited at this Show, but Mr. Turner, of Slough, had some fine Muscat and Black Hamburgh Grapes, Grosse Mignonne Peaches, and Nectarines. Mr. John Waterer's American plants, though not yet at perfection, were still sufficiently advanced to add materially to the attractions of the Show. We shall give a full report next week.

THE APPROACHING MANCHESTER HORTICULTURAL EXHIBITION.

One evening last week I took one of my occasional walks through the Manchester Botanic Gardens, and was particularly impressed with the extensive preparations which are being made for holding the great National Horticultural Show in June next. It occurred to me that a brief account of the arrangements for the occasion would be interesting to your numerous readers.

It is, I suppose, generally known that there is in the garden a large glass building, called the Exhibition-house. This structure is 200 feet in length, and 60 feet in width, and in it all the ordinary flower shows are held. Along one side of this structure, and connected with it, there will be erected a tent of the same dimensions, and the large sliding doors in the side of the building will be drawn back, so that persons may easily pass from it to the tent, or the contrary, thus making the two structures for all practical purposes the same as one. By this means the amount of space available for exhibition purposes will be doubled. There will be a broad walk down the middle of the tent, and a stage on each side for the various collections which it will contain.

In addition to the Exhibition-house and tent, another structure is now being erected at right angles to these, extending along and beyond one of their ends. This consists of a wooden framework, covered with canvas, and is 60 feet wide and 300 feet in length. The internal arrangements of this wing are somewhat similar in style to those adopted at the great International Show of last year, consisting of a series of grass banks and gravel walks. The space of 300 feet is divided into six equal portions, and in the centre of each is thrown up a circular mound, 6 or 7 feet high, and having three tiers or stages all covered with green turf. These are surrounded by a gravel walk 12 feet in width, and on the other side of this walk there are more grass banks of two stages, extending the whole length of the building.

It will be understood from the above description that the general form of the Show will be something like the letter **L**; and it will be evident to the reader, that a person standing in the angle thus formed would be able to see the whole length of both wings without changing his position. This circumstance has been taken advantage of by forming an artificial mound, about 12 feet high, over the top of which the broad walk that runs through the tent first described is made to wind, in its way to the grass banks in the other wing. From the top of the mound the whole of the exhibition will be seen at a glance and will no doubt present a very imposing appearance.

Orchids and the more tender stove plants will be placed in the Exhibition-house; fruit, vegetables, and cut flowers will be arranged in the tent at the side of the building; and the larger specimens of flowering plants, Ferns, and ornamental-foliaged plants will be staged on the grassy shelves which surround the mounds in the long wing. The exit from the Exhibition is so placed that the visitors, on emerging from the building, will find themselves on a broad gravel walk which surrounds the flower garden, situated on their left hand, and a lake of water, with its islands and ornamental bridges, on the right. The various ranges of hothouses, greenhouses, &c., together with the lodges and entrance-gates, are all being repainted for the Show, which, so far as I could learn, is likely to prove a great success. —Thos. Jones, *Gardener, Rusholme.*

CULTURE OF CUCUMBERS IN POTS.

Permit me to add my small stock of experience of the pot-culture of Cucumbers, having formed the opinion, before I saw it advanced in the Journal, that the system was good.

I have grown good crops of fruit on plants placed at the bottom of 11-inch pots, set on an inside Vine border, the plants being surrounded with loam as they increased in height, until it was heaped up above the rim of the pot. I think I may say they were good crops, as the fruit averaged 18 inches long, with a circumference of 7 inches, some being as large as 22 inches by 8¼ inches, and 3½ lbs. in weight.

One of your correspondents mentioned 16 and 18-inch pots in a way which led me to suppose my pots had been unusually small, while another referred to the large size of the leaves of his plants. I have never permitted this luxuriant foliage, for my practice has been to syringe freely, shut up early, and prune severely.—Amateur.

[We have grown Cucumbers and Melons in smaller pots

than the 11-inch ones you use with such success, but we prefer 16 or 18-inch pots as involving less trouble; and our practice has been to place the pretty-well-established Cucumber plant, say from a 5-inch pot into one of 16 inches in diameter, so as to leave a fourth of the pot unfilled, and then earth up by degrees, using turf and zinc rings above the surface of the pots. So far as we recollect we never had a case of Cucumber disease when the plants were so cultivated. You have done so well that we do not advise you to alter your mode.]

BLUE BEDDING PLANTS.

A CORRESPONDENT in the Journal of May 9th, signing himself an "AYRSHIRE GARDENER," regrets the absence of blue bedding-plants. He makes no reference to the lovely little blue Anagallis Monelli, or Italian Pimpernel, I believe. It appears to me as lovely as the Lobelia. I do not know the disadvantages of the Anagallis, unless it is that it requires a very hot sun to make it open. I do not have it here. My former garden was a very sunny one, generally much burnt up. Possibly the Anagallis might not do well in Ayrshire.—A SUBSCRIBER.

STOCKS FOR TEA-SCENTED AND NOISETTE ROSES.

I SHALL be much obliged for some information as to the best stock for working Tea-scented and Noisette Roses upon. I like the Manetti stock for Hybrid Perpetuals, and shall be glad to know if it is equally good for other kinds of Roses. In this wet and stormy part of the country I find that the kinds which are not very double succeed best, as the flowers open more freely than such Roses as Duc de Rohan and Comtesse C. de Chabrillant.

The two sorts that are my mainstay here are Gloire de Dijon and Général Jacqueminot, as they afford abundance of bloom for gathering from the end of May till Christmas, and are both good of their kind, though very old-fashioned in these days.—B., *Dolgelly, North Wales.*

[Excepting Cloth of Gold and Isabella Gray, neither of which is suitable to your wet, cold, and windy part of the country, I have always found the common Noisettes (I keep none of them now), and Tea-scented Noisettes do well on their own roots, on the Briar, and on Manetti. I specially recommend to you Triomphe de Rennes, Solfaterre (south wall), Celine Forestier, Gloire de Dijon, and Maréchal Niel (south wall). The first, third, and fourth prefer a wall, but they will do perfectly well in the open ground on their own roots, on the Briar, or on the Manetti. I name a few easy and abundant and late bloomers suitable to the part of the country described. Some of them are old Roses, but they are still good and valuable. Those marked with an asterisk are extra fine. The colours may be found in Mr. W. Paul's catalogue.

Hybrid Perpetuals.—Anna Ylexieff, Auna de Diesbach, Baronne Prevost, Beauty of Waltham, *Charles Lefebvre, the finest of all Roses; Duc de Cazes, Duchesse de Medina Cœli, Duchess of Sutherland, Empéreur de Maroc, Eugène Appert, Géant des Batailles, Général Jacqueminot, Jean Goujon, *John Hopper, *Jules Margottin, Lion des Combats, Lord Raglan, Madame Alfred de Rougemont, Madame Boutin, Madame Hector Jacquin, not a late bloomer; *Madame Victor Verdier, Maréchal Vaillant, Mrs. W. Paul, Paul de la Meilleray, *Prince Camille de Rohan, *Senateur Vaisse, *Souvenir de Comte Cavour, *Triomphe de Paris, Triomphe des Beaux Arts, not full; Vicomte Vigier, Princesse Mathilde, not full; *W. Griffith, Cardinal Patrizzi, Madame Louise Carique, Mrs. Elliot, Pius IX., Reynolds Hole, and Pauline Lansezeur.

Bourbons.—Louise Odier, Michel Bonnet, very pretty; Bouquet de Flore, Queen, and Sir J. Paxton.

Tea Roses.—*Devoniensis (wall), Sombreuil, extra hardy and fine.

Autumnal Moss.—Salet; Madame E. Ory is the best, but it might not open in a cold climate.

"B." would find the following summer Roses great acquisitions with duplicates and cutting back by instalments, or by the spring removal of one each of the duplicates, their season of blooming may be greatly prolonged. They do well on all stocks:—

Damask.—La Ville de Bruxelles, Madame Soëtmans, or Zoutman. *Gallica.*—Boula de Nanteuil, La Volupté, Kean, Schismaker, pure slate, and Tricolor de Flandres. *Hybrid China.*—Général Jacqueminot, the best; Madeleine. *Hybrid Bourbon.*—Charles Lawson, Coupe d'Hébé, Paul Ricaut.

When I left Rushton I gave my stock of noble summer Roses to Mr. and Mrs. Farquharson. They never had such a Rose season before! I bought the plants of Mr. Cranston ten years ago, and nobly did they bloom and withstand all the shocks of time. I brought here only Schismaker, a most curious Rose, and Madame Zoutman, the finest of all white Roses.—W. F. RADCLYFFE, *Okeford Fitzpaine.*]

FRUIT PROSPECTS AT HADDINGTON, N.B.

IN a note which I sent you in February last, with some remarks on the effects of the intense cold of the 1st of January, which had then become apparent, I stated that some Pear trees in my garden had suffered much, the buds having been apparently deprived of all vitality. As the season advanced this became quite visible, and while the blossoms on the uninjured trees expanded, the embryo buds of the former withered and became like dust. However, we had some fine warm days in April, which brought out the blossoms of all kinds of fruit, and the Pear trees in this district were loaded with flowers. With the exception of those of which the buds had been killed, appearances were so favourable, that I began to think that I should be obliged to resort to the thinning process. However, on the 13th of this month we were visited by a severe frost, the thermometer falling to 25° during the night, and in the morning all Potatoes and plants of equal tenderness, except where under the shelter of a wall with a south aspect, were cut to the ground. Since then we have had a succession of very cold north-east winds, and occasionally some heavy showers of hail, and this has materially altered the complexion of gardens here, which were previously exhibiting a rich and healthy appearance. Many of the embryo Pears which were setting in clusters, are now turning yellow, and dropping off, and although we may still have a partial crop, yet in the cases of the Duchesse d'Angoulême, Gansel's Bergamot, and other tender kinds that require a high temperature while setting, the trees are already almost bare of everything but leaves.

The frost of the 13th browned the tops of the Apple blossoms, and, no doubt, has killed many of the germs, but there is a rich display of flowers, and, perhaps, as many will set as will be sufficient for a crop. Plums blossomed abundantly, but the result in such weather is doubtful. Cherries seem setting badly, and look a scanty crop. The early blossoms of Strawberries are black in the heart, and a certain per-centage of the crop is destroyed, but with good weather soon we may still have a fair crop. The plants look strong and healthy, and bear plenty of flower-trusses. Gooseberries and Currants show well, but I hear complaints of the fruit of the former dropping off in some gardens.

As I write the cold still continues. The thermometer has never to-day (May 22nd) risen higher than 47°. We have seldom seen such unfavourable weather for bedding-out plants. They must either be planted out with the risk of perishing, or kept under cover to be drawn up.—JOHN FERME.

THE FROSTS OF MAY.

SHANBALLY, IRELAND.—We have not escaped without some loss from the effects of the frost during the past winter; yet when I looked this morning (May 23rd), and found the thermometer (Negretti and Zambra's, 3 feet from the ground), at 20°, and everything covered with hoar frost, ice in the gutter of the greenhouse five-sixteenths of an inch in thickness, I began to reflect whether we were past the worst even then. As soon as the sun shone out, with a piercing easterly wind, I found Potatoes, Kidney Beans, young Cauliflower plants, and, I fear, Beet just up, all turned black; Strawberries in bloom, Roses, Peas, and strong Cauliflower plants, hanging their heads as if dying. Even the young shoots of Plum, Pear, and Apple trees, and of Beech hedges are scorched. I hope that others have escaped better, or I do not know what will become of us soon, for, however hard it is to replace Roses and Conifers, I find it far more difficult to satisfy the cook when Cauliflowers and good Potatoes are not to be found.—GEORGE BECKETT, *Shanbally, Clogheen, Ireland.*

NASEBY WOOLEY.—Last Wednesday and Thursday nights (May 22nd and 23rd), occurred the sharpest frost that has been known here for some time so late in this month. At 12 o'clock at night the thermometer in a cool greenhouse stood at 29°,

and one out of doors at 22°. Even on the top of the Melon lights there was ice as thick as a twopenny-piece. The frost has quite killed Kidney Beans and Dahlias, blackened Potato tops, Ivy, Laurel, and the young growth of shrubs and trees. It has done much damage to bedding plants in several places round here. It was so severe as even to catch Pelargoniums covered with mats. I had two beds of Calceolarias out, and it has turned some of the leaves quite black.

Norwich.—A thermometer placed 3½ feet from the ground, facing west, registered

On May 22nd,	8 P.M.	32°,	lowest point	28°
,, 23rd	,,	33°	,,	26°
,, 24th,	10 P.M.	28°	,,	23°
,, 25th			,,	40°
,, 26th			,,	45°

Showing 17° difference between Friday and Saturday nights. Bedding plants are much injured, and in some instances killed, so are Kidney Beans, Potatoes, and Strawberries, the bloom of the latter being black inside. Wind N. to N.E.—F. A. S.

[We have similar reports from many other localities; but the untoward severity is not confined to Europe. In North America it has been so general and persevering, as to rouse even the rustic poets, and this is an extract from one of their outpourings:—

"Well, Spring, youv cum at last, hev you?
The poit sez youv bin a sittin in Old Winter's
Lap—now, aint you ashamed of yourself?
I spose the old feller's bin a bussin you;
I should think he had from your breth
A bein so cold—but that's the way them
Old fellers hev a doin.

"But now youv eum!
We feel your cheering presenz wen we
Git round onto the south side ov the barn!
We hear the hens a kaklin when they've
Laid a eg! We see the Horseradish
A starting up along side the garding
Fens! The wommin is a lukin into
The old tepot after garden seedes!
And all these things make me think youv cum!

"Ef so be I've riled
Ye, Spring, a showing up of yer short cummins,
Jes set it down to havin a poits liseus,
(Tho I haint taken wun out yet, I'low to)."

—Eds.]

WHAT IS MEANT?

A paragraph is worded thus in a prize schedule—"For the best 12 specimen plants of any kind in 12 varieties." Would the Show and Spotted Pelargoniums be admissible as two varieties, the silver and golden-edged Zonal Pelargoniums as two varieties, and the Nosegay and Zonal green-leaved as two varieties?—An Amateur.

[Interpreting the clause strictly, twelve Pelargoniums if all of different varieties would comply with the wording; but we think that the Committee of the Society could not have so intended. They probably meant twelve different species. Why not ask the Committee for an explanation?]

POOLEY'S GROUND TOBACCO.

Now that the Board of Customs has remitted the duty on ground tobacco, mixed in bond with other ingredients to prevent its being smoked or snuffed by human beings, we shall no longer be at the mercy of clouds of insects, so destructive to vegetation at this season.

About ten days since I selected for the application of the above powder a Mirabelle Plum, which had not borne a crop for many years, the leaves having always been destroyed by aphides early in the season. The powder ought to have been applied before the dew was on the leaves and insects, and, if possible, when the air was still. I waited for neither, as I was afraid another day would put an end to all hopes of a crop. However, the tree is now healthy, and the fruit as numerous as well can be. I applied the tobacco dust by placing it in an old worsted stocking, tied to the end of a pole. This dusted every leaf, at the expense of a halfpennyworth of tobacco powder. The same effect was produced on a dozen Rose trees. The powder, unlike others that have been brought out, can be either washed perfectly clean off the leaves or left on, as it is quite harmless. It is applied to the Hop plant when the dew is on at the rate of ten acres a-day, with the apparatus which is used for sulphuring Hops; 1 cwt. per acre being sufficient, at a cost of £2 2s.—Observer.

NOTES AND GLEANINGS.

We are glad to observe that the Royal Horticultural Society, following the example set by the International Horticultural Exhibition of last year, announce that their Great Fête, commencing June 4th, will remain open for five days, and we understand it is intended to admit the public on the Thursday and Friday for 1s. The policy of giving the million a chance of seeing such a grand Exhibition will, doubtless, prove successful.

—— We hope that there will be a very good attendance at the anniversary dinner of the Gardeners' Royal Benevolent Institution on the 27th of June. Sir Robert Peel will preside, and there is a goodly array of Stewards.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Attend to hoeing and otherwise stirring the ground. Weed and thin crops. *Cauliflowers*, *Celery*, and *Lettuces*, plant out; also *Capsicums*, in a warm situation. *Endive*, let a sowing be made directly. Throw in a sprinkling of Early Dutch *Turnip* on a cool border, neither digging nor using manure. It is a mistaken notion to persist in digging ground for Turnips in kitchen gardens, so full of old manures, the Turnip being naturally too gross there, under any circumstances. We always choose the poorest and hardest ground we can find, and merely hoe the seed in, by these means we have always procured good Turnips. Nothing is better than well-burnt ashes of any vegetable refuse for the Turnip. *Kidney Beans*, let full crops be planted forthwith, and a row of Knight's Marrow *Peas*, or the British Queen. The row should be prepared after the manner of a Celery-drill, and the manure completely saturated with moisture. *Potatoes*, earth-up. *Onions*, sow a few for drawing young.

FRUIT GARDEN.

The leading shoots of Peach, Nectarine, and Apricot trees will require to be tacked-in, taking care to allow plenty of room in the shreds. In thinning-out superfluous shoots, it is necessary to foresee what portions of wood will require to be removed at the ensuing winter pruning, and the most appropriate shoots must be accordingly reserved for succession and encouraged throughout the summer. If any shoots laid-in for bearing have failed to produce, they may be gradually removed, in order to afford more space for successional young shoots. In regulating the vegetation of these trees, commence at the base and proceed successively along each branch, but do not dress the lower part of the tree and leave the upper untouched even till next day. Whilst the trees are being gone over insects must not be overlooked. The aphis seems to delight in healthy foliage, but the red spider prefers that which is less thriving, particularly from dryness at the root. It has been stated of this pest, that water is its certain destruction, the water, however, requires to be applied at the roots as well as the tops. Examine grafts and re-clay if necessary. Strawberries in blossom must be well watered. Remove some of the watery shoots from the Currant bushes, and thin the Raspberry suckers.

FLOWER GARDEN.

The different kinds of climbing Roses must be carefully tied or nailed to prevent their being injured by wind. Plant out Dahlias, Salvias, Ten-week Stocks, Asters, Convolvuluses, Nolanas, Campanulas, Kaulfussias, Nemophilas, Indian Pinks, &c., in borders or flower-beds, likewise a few on rockwork. Pot a portion for planting out into beds later in the season, to replace such as have gone out of bloom. Hoe and rake borders, and cut off dead flowers as they appear. Divide Campanula carpatica, and plant it for edgings or in borders of herbaceous plants. Remove any shading from plants recently planted out, and if the weather again set in hot, shade for a few days. Tulip roots should be taken out of the ground when the foliage assumes a yellow, withered appearance. In the present season in particular, from the damaged state of many collections, this should be carefully attended to. Should the bulbs be in a decaying state their exterior coverings or skins should be removed, which will bring many from a flowering state to mere offsets. The buds of Pinks may now be thinned out, and where intended for exhibition they should be reduced to two at most. The laterals may also be removed. Watering once a-week with liquid manure will now be requisite. Carnations and Picotees are, generally speaking, suffering this season, and, on the average, are not looking so well as usual. Attend to the cleanliness of the plants and keep down green fly, giving water and

attending to the general routine culture when required. Pansies should also be shaded from excessive sunlight. They have been severely attacked by the legions of slugs which have everywhere abounded this season. Hand-picking appears to be the only effectual remedy. Dahlias which are sufficiently forward should be staked.

GREENHOUSE AND CONSERVATORY.

Climbing or trained plants now require attention in regard to thinning, training, stopping, &c. If the sun shines very brightly a slight shading would be of benefit for a few hours on very hot days. The inmates of such structures, however, are sometimes very various in character and habit, and the foregoing advice would be more applicable, perhaps, to the various New Holland plants, Oranges, Camellias, &c. In all mild weather the fires in the greenhouse may be nearly or entirely dispensed with. If the weather is genial and accompanied with bright sunshine, heat sufficient for the night may be secured by shutting-up early, not, however, soon enough to scorch. A general rule can scarcely be laid down in such cases to guide the inexperienced. On sunny afternoons the air may be reduced one-half at three o'clock, and altogether shut off at four o'clock. Attend to the various points of cultivation as before recommended, remembering that now is the period for rapid growth. Camellias should be placed in a little warmth to make wood and set their flower-buds; be particular in never allowing them to suffer from want of water. Keep up a gentle moisture by occasional syringings. Azaleas as they go out of flower may also be similarly treated; indeed, all kinds of greenhouse plants are benefited by being kept rather close and warm when making their wood. Rhododendron arboreum and its varieties should be fully exposed to the sun under glass, if you wish to have perfect foliage and abundance of flower-buds. Partial shading to these is their ruin, both as regards their foliage and the forming of their flower-buds.

STOVE.

Thorough cleanliness, free ventilation, plenty of atmospheric moisture, and occasionally a slight shading in very bright sunshine are the prime requisites in this house. No means should be neglected to encourage a free growth at this period in the Orchidaceous tribes in order to have their pseudo-bulbs firm, well-fed, and well-ripened at an early period. As the weather still continues changeable, take especial care that the young shoots of all plants in this house shall not be checked or injured by cold draughts, or scorched by sudden outbursts of sun.

PITS AND FRAMES.

Shift and carefully attend to such plants as are intended to form specimens; sprinkle with water and shut up closely late in the afternoons of hot days. Put in cuttings of choice greenhouse and herbaceous plants, in order that they may be rooted before the pits are again wanted for cuttings to supply the flower garden next year.—W. Keane.

DOINGS OF THE LAST WEEK.

Many of us will remember the Derby day of 1867, for its hail and snow, and bitter north winds, and the keen frosts which occurred on the succeeding mornings of the week, cutting down to the ground all our Scarlet Runners, and Dwarf Kidney Beans not under protection, blackening our forward Potatoes, and causing the pods of forward Peas to look as if they had been scalded by a spattering of water close on the boiling point. Strawberry plants have, as yet, suffered less than we expected, though early on Thursday morning the leaves were like boards, and the bloom encased in sheets of ice; but fortunately for us on that morning, which was the coldest, the sun did not appear until late, and not much then, and the thawing process was effected very gradually. If we had many such seasons, it would be well to revert to the old-fashioned style of flower gardening—the mixture of shrubs, herbaceous plants, annuals, &c., filling up all vacancies with bedding plants, instead of making these the principal decorative objects. This we do know, that not a few, who were kindly but somewhat ostentatiously pitying us for being so far behindhand, are now wishing that they had turned out fewer of their tender plants. We should not like to venture for a fortnight, unless there were a great change, Heliotropes, Perillas, Amaranthus melancholicus, &c. Such plants when thoroughly chilled, seldom do much good afterwards. It is not desirable not to be able to finish combination-beds at once, but in such weather it is safest to do the work at different times, turning out the hardiest plants first, in their allotted places, and afterwards the more tender as the weather becomes more settled.

KITCHEN GARDEN.

One of the first matters attended to after the frost, was sowing Scarlet Runners, Dwarf Kidney Beans, &c., in boxes for future transplanting, placing them where they could be forwarded by heat; and then, as the weather was dry and parching, though cold, ran the Dutch hoe through all the borders and quarters where it could be worked. We likewise earthed-up Cabbages, Potatoes, and Cauliflowers, where possible. Our earliest Cabbages, that we had to forward in pots before transplanting, owing to the four-footed vermin having left a desert of our autumn-planted quarter, are hearting well, and became too thick before we could earth them up. The somewhat forcing treatment which they have received, first potting the little plants, putting them under glass, and then after planting giving them a dash of manure water, has rendered the stems too small in proportion to the heads; therefore, a little earthing-up would have been desirable.

We mention these Cabbages thus particularly for two purposes—first, that it may be clearly known that when all this trouble has to be taken, even such a common vegetable as a Cabbage cannot be obtained quite so soon, or at the same cost as respects labour, as when the plants can be put out at once and be secured from hares and rabbits. It would be sheer folly for a man to meet the competition of the market with Peas for the season, if, instead of casting his seed into the ground, he found he must either transplant his Peas when 3 or 4 inches high, or protect the seeds and the seedlings by wire netting. When people talk about a garden costing so little, it must be clearly understood that there must be none of this wasting, and, what is worse, harassing labour, of doing, having the work undone for you, and then the doing it again as best you can. Secondly, we would say, Let the importance of this doing and doing again in such circumstances never be forgotten by gardeners, as they may rest assured that employers will not forget to look for their favourite dishes at the usual times; though they will very likely forget all about disasters to crops, brought about less from any fault or carelessness of the gardener than their own regulations as to other matters, which will certainly consign a good portion of the garden produce to other quarters instead of lending attractions to a gentleman's table. We do not at present philosophise on the right or wrong in the matter; we merely wish to state the too general fact, that when produce is wanted the destruction from frosts and from the predations of two-footed and four-footed game are apt to be quite forgotten.

Slugs and Seeds.—From all quarters we hear of the numbers of slugs and snails this season. One of our best gardeners has informed us that he has had fifteen distinct varieties this season, and of every variety legions. After the severe frosts one would have thought they had had a nipping. One peculiarity in our own case is, that though we saw too well where they had been, we have been able to find but comparatively few on the surface of the ground, even in mild dewy mornings, when they are generally most abundant. It is just possible, too, that great as their depredations have been, they have been blamed more than they actually deserve. Our own opinion is, that seeds in general have not been quite up to the mark this season, whether owing to the dull wet autumn of last year, or other causes, we could not take upon ourselves to decide; but there can be no question, that in some cases where snails and slugs were blamed, they never had the chance of doing mischief, as the seed rotted in the ground, though receiving all proper treatment. We have received many complaints as respects even Peas, and though some sorts have come up as well as ever, others that were thin were found to have many seeds moulding and rotting that had never germinated, or had come weakly as old seeds will. For ourselves from close picking, the wet of last autumn and an invasion of rats, we did not have the chance of saving any seeds of Peas.

We have already alluded to the general hoeing of all ground where the Dutch hoe can go. Where neatness is an object, a hack draw with the hoe will leave all level and neat, but this is seldom necessary, and the sun and the breeze soon put the weeds out of sight.

The dreaded *Bindweed* has been cut twice already, and where plenty of time cannot be afforded to dig out its roots the Dutch hoe is the grand remedy, as, if the shoots are constantly cut by the time they grow 3 or 4 inches above the soil, the great milky-white roots will be forced to yield up their life in despair, though if left alone half an inch of these roots would ere long make the progress of a garden. Of all weeds this is

the worst, and in some places we are almost beaten by it every season, because it grows too fast and too strong before we can commence to combat it, and it is comparatively of little use to cut it after it has twisted round something to the height of 2 or 3 feet. By that time if you cut the top, the old root has received enough of strength to send out a lot more strong shoots. The most economical mode of extirpating it is not to trouble yourself greatly with the large white roots when digging, but to have a man on purpose, and tell him whatever else he does, a shoot of the Bindweed is never to be seen more than 3 inches in length. We have often resolved to do so, but then when the pinch of so much to do comes, the man cannot pay attention to this work in time, and in a few days if let alone the pretty white-flowered Bindweed that adds, along with the Clematis, such a wild loveliness to our hedge-rows, will cling to and suffocate in its embrace the very plants you would wish to be free from it.

What we can scarcely account for is, that after having been extirpated for years, it will come back again without any apparent cause. Some years ago we had two small pieces of ground, perhaps 24 feet square, quite overrun with it. One piece we kept hoeing, and gave it a kind of summer fallow, planting only some Lettuces, &c., but never allowing a shoot to grow above a few inches in length. On digging we could soon have taken out a barrowload of roots. The other piece was, if anything, worse, and the weed was allowed to have its way until it carpeted the ground with its twisted wreaths. It was then cut with an old scythe, and the crop burned, and a layer of short grass from the lawn a foot deep was placed on it, and allowed to be there until the autumn. In both of these pieces when dug up at the end of autumn, not a root was to be seen. The hoeing, and the cutting and grass-covering, had destroyed the fleshy roots, and for years not a shoot made its appearance, but this season in the latter piece, a few shoots have shown themselves, and we fear they must have found their way in small bits in the dressings applied. We only wish the great proportion of our readers may have no occasion to trouble themselves with such a pest, beautiful though it is; but if any should be so unfortunate, the Dutch hoe used quickly and repeatedly, is the best remedy. Hot short grass laid over the ground long enough will also destroy the roots. Some years ago a lady sent a very fine variety of this climber. The flowers are of the purest white, and very large, quite as large as those of the beautiful Ipomœa Learii, and though in placing it against a wall to show off its beauty, we took the precaution to put the roots in a large pot, and plunged it, these roots and shoots together found their way through and over the pot, and if let alone would soon cover the wall from end to end. We have often wished we had burned the roots instead of planting them in any way except in a woodland wild.

Mr. Keane, whose very timely and particular directions leave us more at liberty to indulge in general remarks, tells us in a recent Number to "manure and dig the ground as it becomes vacant, for the winter crops of Brussels Sprouts," &c. But what if you have no vacant ground? And what if you have no rotten or half-rotten manure? From a scarcity of tree leaves this season, we are short of manure. We expect we must get off the early Potato-beds, to place something beneath them for Celery; and as for crops of Cauliflower, as well as winter crops that will not go between Peas, we must depend chiefly for the help that can be obtained from short grass, and no bad help may thus be had, and with but little preparation. As the Broccoli is nearly cut, we wheel short grass on the piece from the lawn, tumbling it into a good-sized heap, where it heats strongly of itself, and then when shallow-trenched down in a rather thick layer, it yields no bad nourishment to all strong-growing crops. The only drawback to it is, that it requires to be spread and dug in before ladies are about in the garden. Even painters, who are used to disagreeable scents, were fairly overcome by the fumes from this short grass. When not so used, or forming a component part of hotbeds, linings, &c., it is too valuable to be lost, and if made a component of the rubbish-heap, and duly covered over, it will cause all to ferment, and not only communicate a richness to the whole, but, if the heat produced is strong, will help to kill all weeds and roots in the heap.

FRUIT DEPARTMENT.

The cold wet, which hung so long on Peach and Apricot trees unprotected, has much injured the shoots, killing some of the young wood outright. Had they been kept dry by even thin hexagon Nottingham netting, we have not a doubt but that they would have suffered little or nothing. This is one of the facts that will ever make unheated orchard-houses so valuable. The dryness and the stillness of the enclosed atmosphere are the great points of safety. These secured, success will much depend on retarding, by plenty of air, the time of blooming, giving plenty of air then, and only taking advantage of the confined heat from the sun after the fruit is set and swelling. We trust that Plums, Cherries, Pears, and Apples are sufficiently advanced not to suffer much from the frosty mornings. The Apple bloom, and we never saw the individual blooms larger and finer, had been mostly cast a few days before the 20th. A few Cherries are spotted; Gooseberries and Currants, which are very abundant, are sufficiently defended by the foliage to save them from danger. We think the Cherries were marked more by the hail than the frost.

Raspberries.—We have seldom had the canes injured by cold before this season, and we believe the injury was done by the severe frost after the new year. We were surprised that the canes did not break as usual. On examining these faulty canes there is hardly one of them which is not quite green, after moving the bark, and the cane seems sound enough to the core; but the buds along the cane, though looking as if nothing was the matter with them, when closely examined are found hard and dry, as if burnt right to the heart. We think it possible, that if the sap rises in such canes, fresh but latent buds may be thrown out. In such a case, if this took place, the sap would rise without the excitement of expanding buds. We can assign no reason why some canes have thus had their buds destroyed, and others have started and are showing fruit as usual.

Figs Out of Doors.—We have some on a west wall, from which, with but little attention, we have had good gatherings, and better since we left them not fixed so closely to the wall, and that mode of proceeding we learned from Mr. Tillyard, who had fine crops in-doors and out of doors at Bentley Priory. We used to put a few branches, &c., against these trees in winter; but in the press of other matters they were forgotten in the two severe frosts of last winter, and as we could scarcely have the cold more severe the trees were left to take their chance. We expected there would be little show this season, as every Fig that was left was frosted, and withered up and fell off; but what we did not expect to see was this—though the points of many shoots were killed by the frost, a plentiful supply of young Figs is coming from near the base of the shoots, and often all along them, and which would never have shown at all if a few small ones had been saved during the winter near the points of the shoots. As, except in a few extreme cases, the Fig tree never ripens more than one crop out of doors in our climate, we have always recommended the cutting away all fruit larger than a good-sized Marrowfat Pea that appeared on the shoots of the present year's growth in the autumn, as above that size they would almost certainly fall in winter. The above fact is corroborative of the propriety of that advice, and shows that when trees are wholly unprotected it may be carried quite as far in the removing of the summer-shown fruit. On these shoots, now bristling with young fruit, not one was to be seen in March, or even in the first part of April.

Strawberries.—As the houses become shady we have to resort to various schemes, which have already been adverted to, for keeping up a daily supply of fruit; and another reason is that in places where much artificial heat is used, Strawberry plants after the middle of May are very liable to attacks from red spider, and when ripening it does not do to use the syringe so freely as at other times. The frame and the pit, and sashes over borders, must therefore help us instead of shelves in houses.

Out of doors we never saw bloom more plentiful, or in such masses, and as already stated, except by retarding, we do not think the severe frosts have done much harm. The Dutch hoe has been driven through the spaces between the rows twice, to leave a loose surface, and to help to keep in the ground the moisture from the recent rains, and we would have used a sprinkling of soot and lime if we could, but the scuffling of the ground, which is rich enough, will do much to start and unsettle slugs and mice, the two greatest enemies which nets are powerless to keep away.

The keeping the fruit clean is the next consideration, and nothing is better than clean straw, where this can be had; but few places will be able to afford clean wheaten straw at the present prices. The next best material is litter from the stable-yard, well shaken, and packed in to the sides of the rows soon enough to be well washed by the rains; and the next best, if not the better of the two, is long grass before it begins to seed, and which is free from Daisies. This not only answers well

but in fine, dry weather, gives a sweet perfume of new-made hay to the garden. Short grass from the mowings of lawns, though often used, are about the worst, not only because in heavy rains the little bits of grass are driven into the Strawberries, and in close, damp weather, mouldiness of fruit ensues prematurely, but also because such short grass is almost sure to supply a dense crop of Daisies afterwards. Fresh tan is also excellent for the purpose, laid on thinly, and as soon as the fruit is set, as then all the acrid properties of the surface tan are washed away, and neither slugs nor worms like to come in contact with it. We have also tried boards, tiles, slates, &c., with advantage, though in very hot weather the latter are apt to scorch the fruit, and all such means are good for forming traps beneath them for slugs, &c. On the whole, when the flower-stalks are strong, instead of using tiles or boards, we would prefer the simple plan of putting in little sticks 2 or 3 feet apart at the sides of the row, and connecting them with a light string of small cord, which prevents the clusters of fruit falling on the ground. Among some of these modes we trust our humblest readers will find the means for keeping the delicious fruit from coming in contact with the earth. For want of such simple precautions we have seen fine fruit passed through several pails of water, and then dried on paper before being sent to table. In addition to these precautions were the berries for our own use, we would insist on the fruit being picked with footstalks to hold by, and sent to table in the basket in which they were gathered, or merely turned carefully into a suitable dish, without any attempt at dressing them into cones or other shapes, which can only be done by handling every fruit separately. Artistic appearance in all such cases is gained at the expense of true delicacy and refinement.

For ornamental department see previous weeks' notices.—R. F.

COVENT GARDEN MARKET.—May 29.

The weather of the past week has somewhat interfered with operations, but not to the extent of causing much difference in the quotations. There is an abundant supply, and vegetation has rapidly overcome the effects of the late frosts. Continental produce is of the usual character.

TRADE CATALOGUES RECEIVED.

E. G. Henderson & Son, Wellington Road, St. John's Wood, London, N.W.—*Catalogue of Stove and Greenhouse Plants, and Bedding Plants.*

Francis & Arthur Dickson & Sons, 106, Eastgate Street, and Upton Nurseries, Chester.—*Catalogue of Bedding Plants, &c.*

J. Pringle, Wragby, Lincoln.—*Catalogue of Bedding Plants and Roses.*

William Hooper, New Wandsworth, London, S.W.—*Plant Catalogue.*

Hooper & Co., Covent Garden Market, London.—*Catalogue of British and Exotic Ferns.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Books (*Clericus*).—Keane's "In-door Gardening," and Keane's "Out-door Gardening." If you enclose forty postage stamps with your address they will be sent free by post from this office.

Trees Opposite the Front of the Palace of St. Cloud in France (*W. H. C.*).—These, just now in bloom, and with leaves similar to the leaf of the Lilac, but with the bloom shaped like that of the Wistaria, but pink, are either Cercis siliquastrum or Cercis canadensis. Both are grown about Paris, and are very similar to each other.

White Zonal Pelargonium (*G. M. D.*).—If, as you say, your seedling is better than Madame Vaucher, it will be an acquisition. You had better send a cutting bearing trusses of the flowers to the Floral Committee of the Royal Horticultural Society.

Bundles of Asparagus (*J. S. A. G.*).—In Covent Garden Market there is no standard for a bundle of Asparagus. The regular market gardeners put 120 in the best, and 150 in the seconds; but it is brought to market in all quantities, from 25 to 200 in a bundle, by other growers.

Bean (*C. Marsden*).—We cannot decide whether it is the variety "Gem" until we have seen a pod.

Fasciated Asparagus (*John May*).—For a shoot of Asparagus to become flat, and much enlarged, and even to curl round like a ram's horn, as in the specimen you enclosed, is not uncommon. It is termed "fasciated" by botanists. We never saw so large a specimen before as that which you sent. It was fully 6 inches in circumference at the largest part, and weighed 8¾ ozs.

Pelargonium Sport (*C. Gilby*).—It is not at all uncommon for a cross-bred Pelargonium to produce a flower very distinct from all its other flowers. The sport probably resembles those of one of the parents of the plant.

Insect-destroying Powder (*J. Price*).—You must decide for yourself whether you keep the preparation secret, and endeavour to obtain a sale for it. There are many such preparations, and you will require a very considerable outlay before you can obtain attention to it; and even then we fear it would not acquire a remunerative sale.

Black Currant Bud Insect (*W. F.*).—The very minute white insects found in such vast numbers in the buds of Black Currant trees at the present time, in different parts of Scotland, prove to be the young state of a new species of Mite, with only four legs, and a long, cylindrical, fleshy body. Their fully grown state is not known. We can only recommend nipping off and burning those buds which appeared withered from the result of the attacks of these minute creatures, which completely destroy the embryo bloom.—W.

Mrs. Grieve Tricolored Pelargonium (*F.*).—The name of this Pelargonium has been changed to Victoria Regina.

Grapes Spotted (*A. B. C.*).—The small ulcer in your Grapes is called by gardeners "the spot." It is probably caused by the roots being not sufficiently active. If you can have the border a little warmer, and supply the roots once a-week with liquid manure heated to the temperature of the house, you will be likely to check the appearance of the disease. In No. 303 of this Journal is the recipe for more speedily skeletonising leaves.

Pear Trees in Pots Unproductive (*J. Douglas*).—Notwithstanding the particular description of your Pear trees in pots, we can form no idea of the cause of your want of success, unless the plants have been treated too kindly, and have been kept in a close instead of an open house. Nectarines and Plums will set freely in a close atmosphere at night, in which Apricots and Pears will drop and refuse to set.

Oxide of Iron in Water—Hygrometer (*Amateur*).—A small amount of oxide of iron would not, in our opinion, do any harm to Vines, but an extra quantity most likely would, and we would therefore avoid any but the smallest amount. We have not had so much experience with Vines; but we have had pot plants, such as tender Ferns, injured by using water from the hot-water pipes of a hothouse. We cannot tell you where you can have explicit information as to the use of a hygrometer in a vinery, but numerous articles and statements are interspersed in our volumes, and in the "Science and Practice of Gardening." Meanwhile, if you use evaporating-pans on your heating medium, and if in fresty and in bright sunny weather you keep floor, stage, and pathway moderately damp, the hygrometric state of the atmosphere of the vinery will be correct.

Sea-kale Leggy (*R. T. Huntingdon*).—Your plants, we imagine, are old, and have long stems with a crown at the end. We would not take the plants up and divide, though you may take off any stems that are long and straggling, and plant quite up to the crown. March being a good time to do it. We prefer making a new plantation of one-year-old plants in February, and, after allowing them a year's growth, forcing in the following year. Seed may be sown in March, and you will have plants by autumn large enough for making a new plantation, and by the second year fit for forcing. Sea-kale requires a good, rich, light, well-drained soil. We advise a new bed, either from sowing seed or planting young plants, in preference to suckers or divisions from the old plants, the old bed being left until the new one comes into bearing.

Pyramid Pear Trees Unfruitful (*E. H.*).—The most likely cause of the trees failing to set their fruit is their roots having penetrated into bad soil, or from some other cause not having perfected the flower-buds. We advise you to lift the trees carefully in autumn as soon as the leaves begin to fall, and to shorten any thick roots which go down or extend considerably from the stem, but preserve the fibres as far as possible. If the soil is heavy, plant on a slight mound, and mulch around the stems to the full extent of the roots with 3 inches of littery manure.

SMALL IRIS—PROPAGATING STRAWBERRIES (*H. N. O.*).—Your specimen is very imperfect. It seems be either Iris biglumis, ruthenica, or pumila cærulea, all of which will bear the thick, dwarf, pretty character you give your plant, making it so fit for a border-edging plant. With regard to Strawberry runners, the first runner formed is by no means uniformly barren, it is always the strongest; and the second and third runners, though weaker, are generally more fruitful. We would rather avoid taking runners from plants of last August which have not bloomed, and if other plants are plentiful we would not preserve such. As to plants of the age referred to which did not flower, but showed knots of embryo bloom, which came to nothing, you may keep the plants, also the runners from them, if desirable and scarce, as we often find that plants that show such a deficiency in fructification when forced, will fruit freely in the autumn and in the following season; but when there is abundant room for selection, it is just as well to avoid all such specimens in taking runners, as there is always the tendency, however small it may be, to continue such peculiarities. In large places it is next to impossible to attend to these little matters, whilst amateurs by doing so will ensure greater success.

SOIL FOR CAMELLIAS (*Anxious*).—The best soil for Camellias is a good light loam pared off a pasture to the thickness of about 1½ inch. This should be torn in pieces with the hand, and made rather small for such plants as yours. They ought to be potted now in seven-inch pots. The pots should be well drained, and the compost pressed rather tightly about the plants, keeping the collar of these rather high. Having no greenhouse you may place the plants in a cold frame, and after giving a gentle syringing and a good watering draw on the lights. The plants should have air from 8 A.M. until 5 P.M. by tilting the lights at back, and if the days are bright a thin mat thrown over the glass from 9 A.M. to 5 P.M. will keep the foliage from spotting. At five o'clock water, if necessary, and give a sprinkling overhead every day, shutting up the frame afterwards. This treatment may be continued until the plants have made their growth, when they should have air day and night, but about twice as much by day as night, and a slight shade may be afforded them during the hottest part of the day, otherwise afford abundance of air and all the light possible. Keep them well watered, but do not keep the soil in a saturated condition.

VIOLETS IN POTS (*Idem*).—The runners should be taken off and potted in small pots in a compost of turfy loam and leaf mould, with a free admixture of sand. The old plants may be divided, potted in small pots, and placed with the runners in a cold frame, a gentle watering being given. Sprinkle the plants overhead morning and evening, and keep them close and shaded until they are growing freely. You must then admit air and diminish the amount of shading, dispensing with it altogether in a few days, or as soon as they will bear sun. In July shift them into 4½-inch pots, and the most promising may, early in September, have six-inch pots. They should be well watered, but not excessively, and have a good watering overhead on the evenings of hot days. The lights should be drawn down after the plants become established. They are the better of a rather shady place from May to September. Winter in a cold frame, the pots being plunged in coal ashes, with air during mild weather, and the protection of mats over the lights during severe frosty weather.

CHINESE PRIMULAS AFTER FLOWERING (*Idem*).—They should be placed in a cold frame and have air plentifully. Towards the end of June you will see which are worth keeping, and these you may pot in the same-sized pots as before, most of the old soil being shaken from them. The lights should be drawn on closely, and a very light sprinkling of water given every evening, with shade from bright sun. When the plants recover from the potting admit air freely, and keep them well supplied with water. At night the lights may be drawn off and replaced in the morning, tilting them high at back, during dry hot weather, and when heavy rains occur. In August shift the plants into six-inch pots, pursuing the same treatment as before. The plants will bloom finely in autumn, all bloom stems showing before September being pinched off closely. It is only the best that are worth keeping, for seedlings are better for a late autumn and spring bloom.

MIMULUS MACULOSUS CULTURE (*Mimulus*).—We think your plants have gone off in consequence of mildew, caused by their close confinement in a cold frame; but your description being too incomplete to enable us to arrive at a satisfactory conclusion, we cannot advise. We are not quite sure that the plants were not destroyed by the severity of last winter's frost, for although plants might survive out of doors, others in a frame might be frozen, the former having such a good covering of snow. You may sow seeds in the beginning of August in order to raise plants for next year's bloom. Sow in a close cold frame, grow the plants on, pot them off when large enough, and winter them in small pots on a shelf near the glass in a greenhouse. The soil should be kept moist over the winter, and pot as often as the pots become filled with roots. They require protection from frost. We like M. maculosus best, but both are worth growing.

TODEA SUPERBA FRONDS BROWNED (*W. N.*).—The fronds sent appear to have been scorched by a current of cold, dry air. We think there is a deficiency of atmospheric moisture. We would advise a little more heat to be given, and the atmosphere to be kept more humid. The brownness does not arise from damp, nor yet closeness of atmosphere, but from dryness with cold.

CUTTING DOWN STEPHANOTIS (*F. H. F.*).—It is not desirable to cut back the shoots of this plant, as they flower very freely from moderately strong shoots. It is generally sufficient to thin out the old, weak, and useless shoots, and to train the young in their places. This should be done annually. As your plant is bare at bottom, cut it in to within a few inches of the soil, the shoots having dormant buds or eyes below where headed; but it will not flower next year. If you cut it back one-half it is likely it will be as bare of shoots at the bottom as ever. It should be plunged in the pit for some time to secure the breaking of the buds and a good growth. The latter cannot be too well ripened.

RAISING AUCUBA JAPONICA FROM SEED (*H. F. S.*).—The seed should be taken from the berry and sown in a compost of rather light loam. The pot or pan may be placed in a house with a moderate heat, as a warm greenhouse, and if the soil is moist the seeds will vegetate before August, or in spring. They germinate sooner if sown in a hotbed. If they do not vegetate at once keep the soil moist but not wet, and plants will come within twelve months. The seed is best sown as soon as it is ripe, or in March if purchased. Any of the principal nurserymen can supply you with the Verbenas you require.

PEACH AND NECTARINE BLOOMS FALLING PREMATURELY (*A Puzzled Man*).—With respect to the trees which failed in the orchard-house where others succeeded, though all were treated alike, we come to the conclusion, either that the trees which bloomed freely, but refused to set their fruit, were too dry at the roots, or the wood was more luxuriant, and therefore more imperfectly ripened last autumn than the trees that retained their fruit.

RUNNERS FROM UNFRUITFUL STRAWBERRIES (*Essex*).—We have taken runners from plants not fruiting, and they produced as good a crop as those from fruitful plants. We prefer, however, runners from fruitful plants. We are not so particular in this matter with the newer sorts, but you will do well to take runners from fruitful plants only.

ALOYSIA CITRIODORA PROPAGATION (*A. B.*).—Cuttings may be taken from the shoots of the current year, and such are best when from 3 to 6 inches in length, and when the wood is about half ripe, or a little hardened, but not woody. They should have three joints, and not exceeding four if short-jointed. The leaves should be removed from the lowest two joints, and the cutting be cut through with a sharp knife immediately below the lowest joint. A six-inch pot is large enough for a dozen cuttings. The pots should be drained to one-third their depth, and then be filled up with a compost of sandy loam, fibrous peat, and silver sand in equal parts, surfaced with silver sand. The cuttings are to be inserted in the sand up to the leaves or nearly so, and placed round the sides of the pot at about an inch apart. A gentle watering being given the pot should be plunged in a mild hotbed of from 70° to 75°, and slightly shaded from bright sun. The atmosphere should be moist, and the sand also, but not excessively so, otherwise the cuttings will damp off; if the atmosphere is close they will soon root, and be fit for potting-off singly in six weeks. Harden them off when well established.

COMPOST FOR CROTONS (*A Novice*).—We find them succeed admirably in a compost of turfy loam, sandy fibrous peat, and leaf mould in equal parts, with about one-sixth pieces of charcoal from the size of a hazel nut down to that of a pea, and a like quantity of silver sand. The loam may be torn in pieces with the hand, the pieces of root or wood should be picked out of the peat, and the leaf mould should be sifted with a three-quarter-inch riddle. The whole must be well mixed. The whole of the Crotons require a winter temperature of from 55° to 60° at night, and from 65° to 70° by day, and in summer a temperature of between 65° and 75°, with a rise of 10° or 15° with sun and air. They cannot have too much light. Liquid manure may be given when the pots are full of roots and the plants growing vigorously, it may be afforded once a-week. It is not necessary, however, for the growth of fine Crotons.

CUCUMBERS IN POTS (*Amateur*).—We have grown very fine Cucumbers in 12-inch pots, but we prefer them in those 15 inches in diameter. We put in the plants from the pots they are in after potting off, the plants being strong ones that have been stopped. The fruiting-pots are three parts filled with soil, and the plants put in in the centre and up to the seed leaves in the soil. As they grow more soil is added, and we fill to the rim at twice, the first earthing being given a fortnight after potting, and the second in ten days or so afterwards. In about another fortnight we give a top-dressing of rotten manure an inch thick, and water once or twice a-week with liquid manure.

GRUB (*C. C. E.*).—The grub which had destroyed the root of the Strawberry plant is the larva of the common May Bug, or Cockchafer, Melolontha vulgaris.

NAMES OF PLANTS (*A Subscriber*).—1, Azalea pontica; 2, Ranunculus aconitifolius, double-flowered variety; 3, Saxifraga granulata, double-flowered. (*A Constant Reader, and C. W.*).—The Bird Cherry, Cerasus padus. (*John*).—Halesia tetraptera. (*Clee Hill*).—The Horned Violet, Viola cornuta, a native of Spain, and introduced nearly a century ago. (*A. K.*).—Sophora (Edwardsia) microphylla; Andromeda sp. (*An Amateur*).—1, Nerium oleander; 2, Phytolacca decandra; 3, Solanum nigrum. (*C. M.*).—The Cytisus, growing as a standard budded upon a Laburnum is C. sessilifolius. (*Bradford*).—1, Picea pindrow; 2, Abies orientalis; 3, Abies Hudsonii; 4, Cephalotaxus drupacea; 5, Abies Douglasii.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

BRAHMA POOTRAS.

I FIND I omitted the following notes in my communication which appeared in page 349.

The made Brahma Pootras appear to have the pea-comb, and to be without the vulture or falcon hock (certainly more vulture than falcon), but the pure-bred Brahmas are without the pea-comb, and are single-combed, with the vulture hock. The purest-bred Cochins or Shanghaes have the vulture hock, I think; and as to this, I differ from the "Standard of Excellence," which does not commend vulture hocks. I cannot help thinking, that the vulture hock is the proper distinctive characteristic of all feathered-legged poultry, as in the feathered-legged Bantams for instance, and I think that the legs of such sorts of birds are always much better feathered with the vulture hock than without it.

I see that Messrs. Gunson & Jefferson, of Whitehaven, in Cumberland, advertise the Birchen Grey Malays, which are, perhaps, imported by Mr. Jefferson, from the United States, but this I do not know; however, it is from these Malays that the pea-combed Brahmas were originally produced I believe, and it is the Malay, and not the Dorking expression which is thus given to Brahmas, as pea-combed Brahmas stand much nearer to Malays than to Dorkings. The long necks also come from the Malays, and the legs of the pea-combed birds are generally less feathered than those of the single-combed birds, more especially when the latter are vulture-hocked. The Dorking cross may, of course, exist, but I cannot say that I have ever much observed or suspected it, and if common it would, of course, be clearly evident to every close observer. The Americans having a great trade to Shanghae, imported many of the Shanghaes, and with Birchen-Grey Malay cocks these made the pea-combed Brahmas. The Birchen-Grey Malay breed are not uncommon in the United States I understand.

The pea-combed birds I consider to be the original cross made in America. The birds with the brownish markings, I think are the original Brahma Pootras, and those without the brown markings, and which have white, grey, dun, or black markings instead of brown, are the latest made or most cultivated strains of them. The stripe in the chickens is only brown in the brown-marked sorts, and is black in the grey and black-marked sorts, if pure-bred birds of the sort.—TREVOR, OTHERWISE NEWMARKET.

POULTRY-YARD FOR THE WHOLESALE PRODUCTION OF EGGS.

BEING like most of your readers an admirer of the feathered tribe, and always glad to receive and read the opinions and hear of the success of others through the medium of your Journal, I beg to send you the result of an experiment I made a little time ago.

For some years I considered it, as many do, a matter of doubt, whether poultry-keeping in a commercial point of view could be carried out with a profitable result. My experience has solved the question, and I am satisfied now of the practicability of an establishment being conducted with success, where enterprise, skill, and systematical management are combined.

My attention was first drawn to the possibility of making fowls profitable some few years ago, when I had occasion to leave home for a period of two months. My stock then consisted of about 150 Silver-pencilled Hamburghs. Not having any idea that I should be away so long, I did not give instructions to the man in charge what was to be done with the eggs. To my astonishment, on my return I found in a corner of a room an immense heap of eggs, resembling, all but in colour, potatoes shot out of a sack. This naturally suggested to me the possibility of such prolific hens being remunerative, and induced me to investigate by a carefully noted trial what their laying capabilities really were.

I commenced my trial with one hundred Pencilled Hamburghs, ninety-five hens and five cocks, in the month of February, and kept a debtor and creditor account till the end of July, six months, during which period they produced 11,000 eggs, the average being about five to each bird per week. A peck of mixed grain was allowed every day, and boiled flesh twice a-week. On Saturdays the mixed grain was substituted for ground oats and potatoes. Fresh water was supplied in a barrel, and kept continually running or dropping by means of a small tap. It will be seen by the following account that the nett profit of this lot for six months amounted to £18 10*s.* 6*d.* The average laying for the whole year was about two hundred eggs from each hen, and the expense of keeping the whole stock for that period was about £25 or £26:—

FROM FEBRUARY 1ST TO JULY 31ST, ONE HUNDRED SILVER-PENCILLED HAMBURGHS.

PAYMENTS.	£	*s.*	*d.*	RECEIPTS.	£	*s.*	*d.*
Barley and wheat	7	0	0	Sold 11,000 at 5*s.* per 100	27	10	0
Oats	1	2	0	Manure	0	10	0
Flesh	0	14	0				
Potatoes	0	10	0				
Sand and chalk	0	3	6				
Profit	18	10	6				
	28	0	0		28	0	0

As the eggs of this breed are small, I last year crossed them with a Spanish cock, my object being to have the best layers as well as non-sitters and a moderate-sized marketable egg.

Supposing instead of my having kept only these one hundred, I had a farm of 10,000 hens, what would be the result? It would very naturally be remarked, so many fowls together would never answer; but I say with proper management they would in our part of the country; and in many parts of England (I should prefer the midland counties), there are thousands of acres of uncultivated sandy heath land within five or six miles of some of our largest manufacturing towns, on which small hen-houses might be built, sufficiently large to contain from 100 to 150 fowls each, extended over acres of land, allowing an acre for each one hundred birds, with proper cottages and outbuildings for the keepers. One hundred acres of this land could be hired on a lease at a nominal rent, and the droppings of the fowls would improve the soil and make the property more valuable.

The following estimate will show the amount of capital and the profit on a stock of 10,000 hens of the cross-breed:—

PAYMENTS.	£	*s.*	*d.*	RECEIPTS.	£	*s.*	*d.*
Cost of 10,000 breeding hens at 2*s.* each	1000	0	0	Value of stock	2210	0	0
Building eighty hen-houses, two cottages, and outbuildings	1100	0	0	Produce eggs, 2,000,000	5000	0	0
Horse, cart, mincing-mill, and tools	110	0	0	Sale of dung	80	0	0
Horse keep	50	0	0	,, bones	18	0	0
Sundry losses	100	0	0	Sale of old hens after the first five years, at 1*s.* each	100	0	0
Cost of corn	2000	0	0				
Flesh, &c.	50	0	0				
Rent of 100 acres of waste land	25	0	0				
Salary to Manager	100	0	0				
Wages to men and boys	100	0	0				
Cost of breeding 2000 hens yearly to supply stock	200	0	0				
Coals, package, &c.	100	0	0				
Profit	2473	0	0				
	7408	0	0		7408	0	0

I believe the result of the above estimate can alone be accomplished by non-sitting hens. Eggs being the only source of profit, the most prolific layers should, therefore, be selected.

I should myself be very willing to join a party of enterprising gentlemen in an undertaking of this description, as I am confident the result would be satisfactory. A capital of £3000 would be sufficient to carry on a business like the above, which would yield over 75 per cent.

I should like some of your readers who are acquainted with this breed to say if I have overstated its laying capabilities, and whether my suggestions are impossible to be carried out, if so, the reason why.—TOBY.

WOODEN PORTABLE POULTRY-HOUSES.

THESE are desirable under certain circumstances. They can be moved about so as allow the fowls to have fresh runs in distant fields. Lady Holmesdale employs them, and shifts them when deemed needful to different parts of Linton Park. Mr. Schröder, the inventor of an incubator, has designed several. The following are thus pourtrayed and described by him.

"The Single Poultry-house (*fig.* 1), is constructed with three separate compartments—viz., for roosting, laying, and shelter

from weather, and will be found most desirable for general purposes. The roosting portion occupies the whole area of the upper floor; beneath this are laying boxes, occupying one-third of the ground floor, fitted with sliding doors, by which means a broody hen can be shut in for sitting, without the possibility of being

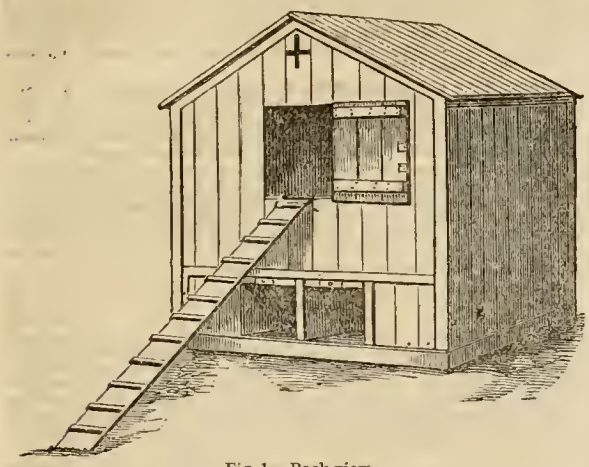

Fig. 1.—Back view.

disturbed. The remainder of the ground floor, open at back, is a general shelter for the birds, providing also the dry dusting-bath, so necessary to the well-doing of poultry. This house gives great command over the birds, is well ventilated, and light and elegant in appearance. Dimensions, 6 feet square. Height, 5 feet to eaves, 6½ feet to ridge.

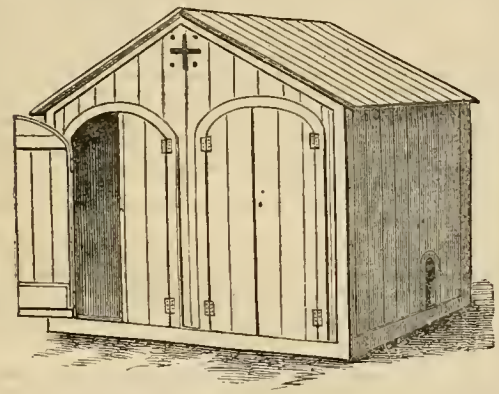

Fig. 2.

"The Double Poultry-house (*fig.* 2), comprises two houses under one roof, on one floor; and where more than one variety of fowls is kept, will be found a desideratum. The building has a division down the centre, forming thus two houses alongside one another, with nests arranged at the back. Trap doors at each side of the building open into separate yards. This house presents a very elegant appearance. Dimensions, 6 feet square. Height 5 feet to eaves, 6½ feet to ridge."

LIGURIAN DISAPPOINTMENTS.

In my few notes on bees, which appeared in "our Journal" of 11th December, 1866, I mentioned having introduced two stocks of Ligurians into my apiary during the preceding autumn, with what results the following narrative will show.

The first stock I received was purchased of Messrs. Neighbour & Sons, and arrived during very warm weather in the middle of September, 1865; they reached me in good condition, and passed the winter safely, were forward in the spring, but although with such a cold May as that of last year I did not attempt increasing them until the 30th of that month, I had by the middle of June three stocks formed from them. I then, for certain reasons, ceased to multiply them, and well was it that I did so, for the original stock eventually died of foul brood during the following winter, and all the stocks formed from it have fallen a prey to the same dire disease. A hybridised queen, which with another was received last October from Mr. Woodbury, also perished during the severe weather in March of the present year, leaving honey and combs useless. Messrs. Neighbour, on being communicated with on the subject, at once offered to exchange the infected stock for a recently imported one with a pure young fertile queen. This stock I received about the middle of last month (April), in good condition. The queen breeds well-marked workers, and a few beautiful Ligurian drones have appeared. I may add that my apiary was originally, and I have every reason to believe that it now is, perfectly free from the disease thus imported into it, and which has proved itself so fatal.

The other stock of Ligurians was purchased of Mr. Carr, of Newton Heath, near Manchester; it arrived early in October, 1865, robbed of its heavy honeycombs, so that it might travel better; yet in spite of this precaution a great many bees lost their lives during the journey. The remaining bees were headed by a diminutive but good-coloured queen, which bred good-coloured workers in a small eight-framed box 12 inches square by 9 deep, which, as well as the frames, was painted inside and out! The bees, as might have been expected, never did well in such a toy, coated as it was with oil paint. After taking in their autumnal store of food they were, in spite of upward ventilation, much troubled throughout the winter with internal moisture, and in the spring were in a wretched condition. The queen did not begin to lay until the middle of April, and during the summer never filled more than the middle of three or four of the frames with brood, so that it was the end of July before the stock was in any way healthy or strong. The honey season being then over, I had to give it about 14 lbs. of food before it was safe for the winter. The queen of this wonderfully prolific strain of Ligurians ceased laying about the end of August! Frequent examination during the spring of this year only revealed the mortifying fact that this queen, which was advertised in your Journal as having been bred from the "most beautiful strain of Ligurians to be found in Europe," had not laid a single egg! I know not how prolific she might have been before she came here, but after she came into my possession she certainly showed none of those great breeding powers attributed to Mr. Carr's strain of Ligurians, and up to the 29th of April had not commenced egg-laying. I therefore took her from her remaining subjects (about twenty in number), and placed her at the head of a strong stock of black bees, whose queen had been removed eight days and royal cells one day previously. She was well received, and lived in the hive until about the 3rd of May, during which time she never laid an egg, and was ultimately missing on the evening on that day. So ended my Ligurians. The case and particulars were duly reported to Mr. Carr, but I have never received any answer from him.

I have since obtained a stock of pure Ligurians from Mr. Woodbury, which, all being well, will, with the other sent by Messrs. Neighbour, shortly increase the Ligurian element in the apiary of—J. B., *Bracken Hill.*

[I am very sorry to learn from the foregoing narrative that Messrs. Neighbours' bees are infected with foul brood, and trust that "J. B." is correct in believing that none of the seeds of this insidious malady are lurking either in the second stock received from them, or in his own apiary. Although it is now approaching four years since I finally got rid of it, I have too vivid a recollection of my own woeful experience of foul brood not to sympathise most sincerely with any bee-keeper whose apiary may be suffering from so terrible a disease. I trust the Ligurian stock which "J. B." has recently received from me, and which I know to be thoroughly healthy as well as perfectly pure, may do something towards compensating him for his previous disappointments; but it does appear to me that Mr. Carr should either refund the money paid for the abortive Ligurians, or replace them with a good stock in a properly constructed hive.—A Devonshire Bee-keeper.]

MEAD, METHEGLIN, AND HYDROMEL.

A correspondent of The Journal of Horticulture (May 9th), inquires for receipts for making mead and metheglin. I enclose some taken from an old book of receipts of Sir Kenelm Digby's, published in the year 1675, by Henry Brome.

"*Mr. Webbe's Meath.*—Master Webbe, who maketh the king's meath, ordereth it thus:—I take as much of Hyde Park water as will make an

hogshead of meath, boil in it abont 6 ozs. of best hops for about half an hour; by that time the water will have drawn out the strength of the hops. Then skim them clean off; then dissolve in it warm, about one part of honey to six of water; have and beat it until the honey be perfectly dissolved; then boil it, beginning gently till all the scum be risen and scummed away. It must boil in all about two hours. Half an hour before you end your boiling put in some rosemary tops, thyme, sweet marjoram, one sprig of mint; in all about half a handful, and as much sweet-briar leaves as all these; in all about a handful of herbs, and 2 ozs. of sliced ginger and 1 oz. of bruised cinnamon. Let these boil about half an hour, then scum them clean away, and presently let the liquor run through a strainer cloth into a keever of wood to cool and settle. When you see it is very clear, lade out the liquor into another keever carefully, not to raise the settlings from the bottom. When it is cool and perfect clear, then run it into a cask that has been used for sack, and stop it up close, having an eye to give it vent if it should work. When it hath wrought and is well settled, which may be in two months or ten weeks, draw it into glass bottles, and it will be ready to drink in a month or two. If you would have it sooner ready to drink you may work it with a little yeast."

"*White Metheglin of my Lady Hungerford, which is exceedingly praised.*—Take your honey and mix it with fair water until the honey be quite dissolved. If it will bear an egg to be above the liquor, the breadth of a groat, it is strong enough; if not, put more honey to it till it be so strong, then boil it, and when skimmed put into it one handful of strawberry leaves, and half a handful of violet leaves, and half as much sorrel, a dozen tops of rosemary, four or five tops of balm leaves, a handful of hart's-tongue and liverwort, a little thyme and red sage. Let it boil an hour, then put it into a wooden vessel, where it will stand till it be quite cool; then put it into the barrel, then take half an ounce of cloves, as much nutmeg, four or five races of ginger; bruise it and put it into a fine bag with a stone to make it sink, then stop very close. The herbs and spices are in proportion for six gallons."

"*A Receipt to Make Metheglin as It is Made at Antwerp.*—Contains one measure of honey to three of water; 1 lb. of hops to every barrel of meath; 1 lb. of best raisins to every gallon of water."

"*Strong Mead.*—Take one measure of honey, and dissolve it in four of water, beating it long up and down with clean wooden ladles. The next day boil it gently, scumming it all the while till no more scum riseth. The rule of its being boiled enough is, when it yieldeth no more scum, and heareth an egg. Then pour it out of the kettle into wooden vessels, and let it remain there until it be almost cold. Then turn it into a vessel where sack hath been."

"*To Make Honey Drink.*—Two quarts of water, 1 lb. of honey. Boil and skim it. Bottle it next day, putting in each bottle four or five, cloves and as many races of ginger. Stop it close, and it will be ready to drink in ten days."

"*Hydromel*, as it was made weak for the Queen Mother, and was exceedingly liked by everybody.—Take eighteen quarts of water, and one part of honey. When the water is warm put the honey to it. Continue skimming it as long as any scum will rise. Then put in one race of ginger, four cloves, and a little sprig of green rosemary. Let these boil one hour, then set to cool till it be blood warm, and then put to it a spoonful of ale yeast. When it is worked up, put it into a vessel of fit size, and after two or three days bottle it. You may drink it after six weeks."

OUR LETTER BOX.

Chicken Dead in the Shell (*B. B.*).—If out of nearly three hundred you have only lost two chickens in hatching, you have been indeed fortunate. The chicken enclosed to us is malformed, and would not have lived if it had extricated itself from the shell. The other you mention was trampled upon by the hen probably.

Books (*M. H. L.*).—"The Poultry-Keepers' Manual." You can have it free by post from our office, if you enclose your address and 7*s.* 10*d.* in postage stamps.

Hens not Laying (*M. H. L.*).—Your hens are feverish. Discontinue the whole corn for a time, give meal instead, and feed plentifully on lettuce. If they have no grass run let them have one, and they will soon lay. Nothing is a more certain sign of fever than for the hen to sit so long on the nest without laying. If you cannot give them a grass run, give them large sods of growing grass.

Eggs not Hatching (*Idem*).—The eggs were what is called clear, and would have remained the same had the hen sat three months. They were not fecundated, and therefore were not susceptible of change. The cause of failure was no doubt the same in both cases, or it may be in the first place the eggs were frozen. In that case they would produce nothing, but they would change.

La Flèche, Crève Cœur, and Houdan Fowls (*La Flèche*).—Our experience of the French breeds is that the Houdan is the really hardy bird. La Flèche and Crève Cœur seem subject to epidemics. Some time since all our cocks died off, young and old. We do not consider them strong, but the hens are stronger than the cocks. The best treatment we have discovered is to withhold water, allowing them only a very limited quantity twice a-day. We some time since visited the parts of France where most of the poultry is bred, and we were confirmed in our opinion that the cocks are weaker than the hens, by being told the same observation had been made there. As we are bound to give all our experiences, and happy to do so, we can say that at an establishment in Wales the La Flèche have succeeded better than any fowl had ever done previously. We believe La Flèche chickens want more food than any other, and the old birds are great eaters.

Game Cock's Bill Damaged (*North Lancashire*).—In competition half as close as it generally is in the Game classes in your county, the slightest defect, even an accidental one, is sufficient to turn the scale against you. The perfect can hardly win, the faulty cannot hope for success.

Colour of Dorking Chickens when First Hatched (*A. B. B.*).—It is an old saying that any colour is admissible and correct in a coloured Dorking, save black and white. Many chickens hatched apparently white become grey and silver grey, and apparently black ones are only the dark birds that are so much admired both for weight and beauty. We have never seen a Black Dorking.

Millet Seed and Millet Meal as Food for Poultry (*B. B.*).—We have tried millet and millet meal for fowls, but it did not answer, as they disliked it. It makes the heaviest meal of anything we have tried. The French use meal made of buckwheat. We think both millet and buckwheat are better for fattening than for making flesh and muscle.

Combs of Dorking Hens (*E. M. B. A.*).—The comb of a Dorking hen is of small importance. It should be moderate in size, well serrated, and should hang over the side. Those who are skilled in, and very observant of poultry, look "awry" on very upright combs in hens. The ladies who delight in such distinctions generally go on till they crow. For leg-weakness give nourishing diet, plenty of green food, and four grains of citrate of iron daily until the bird's strength is improved.

Cochin-Chinas not Laying (*Kitty*).—We are very unbelievers in the assertions that are made that three or four healthy hens do not lay at this time of year. Our belief is that your hens lay and eat their eggs. It is a simple impossibility that four Cochin-China hens should go on without laying till now, and you are highly favoured that they are not broody, or at least three of them. Our fate is very different; when we went into one of our houses this morning each corner was tenanted by three or four hens, swelled to monstrous dimensions, and endeavouring to produce life in the largest stones they could scrape together. We were glad their language could not be interpreted when they remonstrated against being moved.

Bantams (*A. B. C.*).—Your White Tropical Bantams are the Japanese Silky fowl, or an offshoot from it. Any dealer can procure them for you.

Pigeons (*H.*).—We have not seen more than the first part of the work on Pigeons, by Mr. W. B. Tegetmeier and Mr. Harrison Weir; but a disappointed purchaser writes to us that "the second part contains twenty-two pages and a half, of which ten pages and a half are quotations, and the remaining twelve contain nothing new. If Mr. Tegetmeier makes the future parts like the two I have, the work will be a pretty picture book, but not one from which the experienced fancier will learn anything; still I rejoice at the publication of 'Pigeons,' as it will increase, I trust, the number of admirers of these beautiful birds. There are four illustrations—a pair of Frillbacks, those uncomfortable-looking Pigeons which, like the sight of Frizzled Fowls, fill one with an uncontrollable longing to smooth their feathers; then a pair of Fantails, in which Mr. Harrison Weir's skill is seen very favourably; then a pair of Blue Brunswicks and a pair of Black Priests, very priestly-looking indeed, with M.B. waistcoats and shaven crowns. I fear we are doomed to an increased invasion of German Toys, mere birds of feather. I wait anxiously to see, not the drawing, for that is sure to be excellent, but the colouring of the Almond Tumblers, which will test more than any variety the powers of Leighton Brothers. In how many bird books the colours are too bright! Morriss's 'British Birds' is a glaring instance of this fault, and it is one which a colour artist should try to avoid."

Rabbits (*A. H. E.*).—Your Rabbits are unusually good, and well developed for their age.

Canaries Laying Shell-less Eggs (*Suthings*).—Place a piece of old mortar in the cage, and keep it there while the birds are breeding. One cock and two hens will do very well in the same cage. Birds in a cage and placed in the aviary where others are flying loose will make no difference to their breeding. Canaries will endure cold in winter in the house without fire, either in cages or loose in a room; but care should be taken that there be no draught, and that they be not removed suddenly from a warm place to a cold one.

Ferrets (*A Constant Reader*).—We never heard of any difficulty in keeping them. Any raw meat, birds, &c.; about the size of a mouse daily is enough for one. They should be kept very clean, and the floor of the hutch covered thickly with sand, or they become footsore.

Payne's Improved Cottage Hive (——).—It can be obtained of Messrs. Neighbour, High Holborn.

Questions on Bees (*Stupid*).—1, Langstroth on the Hive and Honey Bee, published in America at 1½ dollar, and procurable in England for about 7*s.* 6*d.* 2, We do not think it matters much if the ventilators in bee glasses do not reach to within 2 inches of the bottom.

Small Bee (*A South Lancashire Bee-keeper*).—The small bee is named Andrena albicans, and is common throughout England at this season.

Dressing Hives and Feeding Swarms (*J. M. B. K.*).—We know not how far it may be usual to dress or anoint hives intended for swarms with either salt or sugar; but we believe it to be a custom more honoured in the breach than the observance, being of opinion with Mr. Taylor, that "a dry clean hive is preferable." We do not, however, consider that the dressing with sugar and salt injured the cast which issued on the 19th inst.; the fact, doubtless, being that the bees are dying, if not already dead, from starvation, owing to the recent inclemency of the weather.

POULTRY MARKET.—May 29.

We have still a dearth of poultry, and consequent high prices. We are suffering from the terrible winter, and the poultry we are waiting for makes little progress in this uncertain and trying weather.

From observations taken near London during the last forty years, the average day temperature of the week is 70.5°; and its night temperature 47.1°. The greatest heat was 90°, on the 6th and 7th, 1846; and 12th and 13th, 1842; and the lowest cold 30°, on the 11th, 1865. The greatest fall of rain was 1.48 inch.

WHAT CAUSES THE VARIEGATION OF LEAVES?

THIS day I have sent you a common Cabbage with the leaves white-edged; not that I think it of any service, but because there is just now so much talk of the means of obtaining variegation in the foliage of plants, and so many opinions are given.

Some think that our Tricolored Pelargoniums are the result of chance, whilst others affirm them to be the result of careful cross-breeding. My own experience leads me to form the latter idea; but the question to me is, Does the plant absorb the colouring matter from the soil in which such plant is grown? If so, can the colour of the foliage of plants be altered at pleasure, or at the cultivator's will, like the bloom of the Hydrangea? If so, can colouring matter be so supplied as to form any distinct-coloured foliage desired?

Most of us know well enough how high cultivation and rank luxuriant growth spoils the variegation of the foliage, and induces a hue of dark olive green, and we also know how difficult it is to fix variegation sometimes.

In my opinion very little practical information indeed has been given as to the law of Nature, if indeed it be a law, which causes and affects variegation. In the case of this Cabbage, Was the variegation in the germ of the seed, or was it in the soil? Would it have been so variegated grown in any other place or position? Nothing has been done artificially to cause it to present the appearance which it does, neither is the leaf of any other plant in the whole square affected in any way.

When any one can take the seed of a plant, say of a Brassica, saved carefully from a pure green plant not impregnated with any other, and can grow from seed so saved according to his will variegated plants—then, and not till then, shall I think we have any practical information on the subject. Many of your readers will, of course, differ from me.—F. Flitton.

[Our correspondent is somewhat unreasonable on this mysterious subject. Florists have some "practical information" relative to the production of variety in the forms and colours of flowers, although they could not take a seed and compel it to produce a variation desired. Variation in colour, whether in animals or plants, is one of the many phenomena in Nature concerning which there speedily arises a "Why," to which we cannot assign the "Because." Why colour varies in the coats of horses and of other domesticated animals—for it is only among those domesticated that such variation occurs—defies explanation; and similarly inexplicable is it why some Roses are red, some white, and some "York and Lancaster." So, also, in the case of leaves always naturally coloured, as those of Caladium bicolor, Orchis maculata, and many others, we know not why in one part the colouring should differ from that in another part. Yet that these phenomena are unexplained is no more a subject for surprise than that we cannot tell why eyes are sometimes blue and sometimes hazel. We do, however, know some facts connected with the variegation of leaves, and they are worth gathering together.

In the first place, it is well to remember that leaves and flowers are readily changed into each other—that is, a bud may be made to produce either leaves or flowers. "I have," says Mr. Knight, "repeatedly ascertained that a blossom of a Pear or Apple tree contains parts which previously existed as the rudiments of five leaves. I have often succeeded in obtaining every gradation of monstrosity of form, from five congregated leaves to the perfect blossom of the Pear tree." So that the elaborating vessels of a leaf are capable of producing secretions coloured otherwise than green is not a matter for astonishment.

Now, the most usual variegation in leaves is some portion of them being white. Dr. Morren, Professor of Botany at Liège, examined microscopically the white portions of the variegated leaves of Euonymus japonicus, Syringa vulgaris, and other plants, and he uniformly found that they had cells filled with air or gas in immediate contact with the chlorophyll, or colouring substance; but the parts of the leaves which were green had no such cells filled with gas in contact with the chlorophyll. Unfortunately that gas was not analysed, but he concluded from his examinations that a corresponding whiteness of the chlorophyll accompanied that gas. We believe that that gas is oxygen, for Sennebier ascertained that the discolored parts of leaves are incapable of exhaling oxygen, which the green parts do exhale abundantly when exposed to light. Now, oxygen gas is a great bleaching agent, and its presence in excess would cause the whiteness. As an example, from a green part of a leaf of the Cabbage sent to us by Mr. Flitton, we removed the cuticle and applied a solution of chloride of calcium (bleaching powder), and the green chlorophyll speedily acquired the colour of the white variegated parts; now, such bleaching was effected by highly oxidising the chlorophyll.

An excess of oxygen, however, sometimes generates an acid in leaves, and this acid, varying in different leaves, and coming in contact with different substances in their sap, differs in the colour which it produces. M. Macaire Princep made experiments upon this subject. He found that leaves of deciduous trees in autumn absorb oxygen when exposed to light, and form an acid, which changes the green of the chlorophyll first to yellow and then to red. He also found that by soaking a red leaf in a solution of potash it became again green, evidently in consequence of the potash neutralising the acid in the leaf. He found this the case even in the red under-surface of a Cyclamen leaf. He carried his researches further, and concluded from them that the red and yellow colours of flowers arise from chlorophyll being altered, as it is altered, when leaves assume their autumnal tints.

Chemical research can go no further, for it cannot unveil Nature at her work, and reveal how she manages that cells in juxtaposition shall some produce secretions that whiten, others that redden, and a third set that render the chlorophyll yellow. The chemist's progress is similarly barred in the animal creation, for he cannot explain the somewhat similar phenomena of the varied colours in piebald horses, brindled cows, and tortoiseshell cats.

Yet we can conceive something of the agency employed. A very slight alteration in the chemical composition of a vegetable secretion totally changes its qualities. Tannic acid differs only from malic and tartaric acids in having a little less oxygen. Yet tannic acid with the iron in sap strikes a black colour, which the other two acids do not. This may be the source of the horseshoe in Pelargonium leaves. Then, again, ammonia, present in all cultivated plants and soils, changes, says Liebig, into splendid blue or red colouring matters when it comes in contact with some bitter principles, or even tasteless matter, as that of Roccella tinctoria.

If a departure from usual colour is a symptom of disease, then variegation is such a symptom; but if disease is properly defined as a condition where one or more functions of the plant are altogether impeded, then it is open to doubt whether variegation satisfies the definition. We know that variegated plants are for the most part as hardy and as prolific as those with leaves of the normal colour.

It has been said that we shall never have a blue Pelargonium, but we do not include this in our list of impossibilities. There is no evidence to show that Pelargoniums are excluded from what has been called the cyanic series of colours. The blotch of some varieties tends towards a purple tint, and if a Pelargonium could be fertilised by the pollen of some one of its blue-flowered relatives, the Geraniums, we think the colour desired would be obtained.]

ROSES ON MANETTI STOCKS.

It was with much surprise that I saw in a monthly contemporary an assertion that "Roses on the much-vaunted Manetti have not escaped [the effects of the severe weather] notwithstanding that they present no difficulty in the way of giving protection." It is certain that they present no more difficulty in this respect than those on their own roots, and not so much as those in the form of standards, which when grown in considerable numbers, and on account of their form, must almost of necessity be left unprotected; hence they have been killed by thousands. Not so with Manetti Roses, except where, as Mr. Radclyffe says, people have not taken the pains to keep them out of mischief; but here, as with him, the case is totally different. Out of 300 plants on the Manetti stock, I have lost but three, and these were small weak plants that probably would have died under any circumstances. They were propagated by artificial heat under glass, planted out last summer, but made no growth. Their names were Xavier Olibo, Madame William Paul, and Souvenir de Bernardin de St. Pierre.

All the beds of Manetti Roses, with a trifling exception, were covered last September with loose stable litter about 3 or 4 inches thick. This, with 12 inches of snow, was the protection afforded, but it was very effectual. Scarcely any portions of the plants below the snow-line were killed, nor were the exposed shoots above it injured generally. The latest growth and the ends of the shoots suffered. Owing to peculiarity of situation, the frost in January was less severe here than in many places.

The cold of January being followed by mild and even warm weather in February, not only Roses, but every kind of plant began to break into foliage with the rapidity that always succeeds severe temperature. The thermometer frequently stood at 50°, and the night temperature was comparatively high. Then succeeded the check in March, which apparently told more than the previous ordeal in January; for many plants, especially standard Roses, which seemed to be alive and pushing, were thrown back by the abrupt change of weather. In the first week in May the thermometer sometimes indicated from 85° to 90° in the sun; from the 21st to the 25th there was frost every night; on the 22nd the ground was white with snow for some minutes about 12.30 in the middle of the day, and again in the afternoon. These violent and sudden changes have already marked the present year as an exceptional one that will long be remembered.

It is not surprising that Roses have suffered much, but the losses would undoubtedly have been less if they had been grown in a form in which they could be more or less protected; and that protection afforded them, they may be preserved through the severest winter if a little care be bestowed upon them. I have not many Tea Roses, but I have not lost one. Noisettes trained against the house and too large to be covered have suffered most. Solfaterre and Ophirie have lost three-fourths of their wood. Isabella Gray and Maréchal Niel (smaller plants) have not had any of their shoots killed, but they are breaking languidly, and indicate an impatience of the many checks they have received. Cloth of Gold I have cut down to the ground; though not killed, the wood was unsound. Céline Forestier and Gloire de Dijon (twenty plants each) are uninjured, and are now showing bloom-buds. Triomphe de Rennes, ten plants slightly injured, one killed.

Rose amateurs must follow Mr. Radclyffe's advice if they wish to have good Roses; they must not be afraid to use the pruning-knife freely. All imperfect wood should be cut away. No good ever results from leaving half-dead wood and unsound shoots: hopes founded upon such are false hopes.

Manetti Roses, as above stated, are safe. I have never allowed them to become large plants. Close pruning is best on light soils. They make shoots from 4 to 6 feet long in a season; but I rarely leave them higher than 3 feet. The latest-formed foliage has slightly suffered from the frosts of May 21 and succeeding days, being a little blistered, but not destroyed. I have seen some, where the frost was more severe, shrivelled and black like tinder: the first blooms are therefore lost. Mine have escaped. I enclose specimens of leaves fully developed prior to the late frosts taken from Manetti plants exposed to all the vicissitudes of the weather.

Of briar Roses I have little to say, regarding them as things of the past where Roses can be better grown on their own roots or on the Manetti; and here, where they should be discarded, I retain them only till such time as I can supply their places with others in either of these forms. The mortality has been considerable—about sixty dead or rendered useless out of five hundred. Maréchal Vaillant, Gloire de Dijon, Céline Forestier, Charles Lawson, and Coupe d'Hébé do well as standards.

I wish to correct a misstatement in my report on Messrs. Ivery's Nursery, at p. 341. For Cedrus Libani to be described as nearly every plant killed or so severely injured as to be worthless, is not quite true; many are greatly injured and some are quite killed, but there are some uninjured. Of Cupressus sempervirens, no plants have escaped above the snow-line. The large specimens of Pinus excelsa that I thought were dead, are not so; they are very severely injured. Arbutus photinifolia, Milleri, magnifica, and others are all killed above the snow-line, and much injured below it.—Adolphus H. Kent.

THE FROSTS OF JANUARY, AND THE FROSTS OF MAY.

The damage done by the frosts last week, particularly on Friday night, or Saturday morning, (May 24th-25th) when the temperature fell 10° below freezing, makes me look back upon the winter's frost as a trifling affair of the past. The young wood of the Abies, Piceas, Hollies, Laurels, Azaleas, Rhododendrons, Ash, Beech, Oak, Chestnut, &c., is nearly all killed. Potatoes and Dwarf Kidney Beans are killed to the ground. All the kinds of Brassica I am saving for seed (excepting my Eclipse Broccoli, which is now in fine head), are at present in bloom, and I think are very much injured. The Strawberry bloom is nearly all destroyed. Gooseberries and Currants are fast falling off; the Cherries are frozen through, and all other fruit severely injured. I never saw such destruction by frost before.—John Cattell, *Nursery, Westerham.*

The following is a list of some of the consequences of last January's frosts at Mr. Cattell's nursery:—

Abies Douglasii, only the foliage slightly injured.

Abies Mormda, very much injured, portions of the wood killed back.

Araucaria imbricata, being on elevated ground, only slightly injured.

Cedrus deodara, in one portion of the grounds, very much injured, some plants being nearly killed, in other parts more elevated not injured at all.

Cupressus macrocarpa, nearly all killed down to the snow line.

Pinus insignis, all large plants quite killed.

Podocarpus andina, very much injured.

Taxodium sempervirens, the growth of last year mostly destroyed.

Irish Yew, foliage of many much injured.

Arbutus, in some portions of the grounds quite killed down, in more elevated parts slightly injured.

Laurustinus, the same.

Aucuba japonica, slightly injured.

Sweet Bay, killed down to the ground.

Holly, Variegated, very much injured, some fine standards quite killed.

Holly, Common Green, some nearly killed.

Laurels, Common, the foliage much destroyed, in some cases the wood killed.

Oaks, Evergreen, some nearly killed.

Rhododendrons, some kinds nearly destroyed.

Sorts of Pears that suffered most, but which were worked on Quince—Beurré d'Aremberg, Duchesse d'Angoulême, Seckle, Louise Bonne of Jersey, and Fondante d'Automne.

Roses, of all classes, have suffered severely. Of standard Hybrid Perpetuals it is difficult to say which is the most hardy, for those which were supposed to have escaped have lately died, being so much injured they could not recover. The Moss kinds seem to have suffered least. The Hybrid Bourbons and Hybrid Chinas have been very severely injured; some of the Climbers—Ayrshire, &c., were slightly injured.

Lowest temperature registered 7° below zero—that is, 39° of frost, January 4th, 5th, and 6th.

ORIGIN OF VARIEGATED PELARGONIUMS.

[The following is the paper on this subject which Mr. Wills intended to have read at the Royal Horticultural Society's Meeting, May 21st.]

My intention was, had there been time, to have brought the whole of my specimens of the old Pelargoniums before the meeting. They would have illustrated the progress that has been made from the year 1710 to the present time. I have to thank Mr. Davies, gardener to Lord Bridport, for several of these curious old forms. One of them, Miller's old variegated, is especially interesting, as being the first variegated Pelargonium ever seen in this country, and probably the parent of all the beautiful variegated forms we see around us on this occasion. I have also in my collection plants of two of the wild Cape Pelargoniums—namely, Pelargonium inquinans, the parent of all the plain-leaved section, and the wild Pelargonium zonale, which is the parent of all the zonate varieties. These old varieties, which have been so long cast aside as worthless, are, nevertheless, very interesting, as being the parents of the magnificent host of variegated Pelargoniums we see around us.

I am very much inclined to think that it is not by man's agency that our first variegated kinds were obtained. My opinion is, that Nature in the first instance received no assistance from man, but that some of the earliest variegated kinds originated naturally. The first silver-variegated Pelargonium of any note was sent out many years ago by the Messrs. Lee, of Hammersmith, and named by them Lee's Variegated Scarlet; and I think there can be little doubt but that the origin of this variety was a sport from a green parent, which may have been naturally impregnated by the pollen of Pelargonium zonale variegatum. One of the seedlings from this natural cross, although perfectly green for several years, may have had the tendency to variegation, and many years may have elapsed before the plant had sufficiently matured itself to enable it to produce a variegated sport. In support of this view, I may quote a letter I received some months ago from Mr. Davies, and in which he says, "Many years ago I raised a quantity of seedlings from Lee's Flower of the Day. One of them produced a beautiful bright scarlet flower, the flower-truss of which was very large. The original parent, which is now about 18 feet high by 10 feet wide, continued perfectly green till about four years ago, when it occasionally threw out sports, producing variegated leaves on different parts of the plant, which are generally greatly admired." Many instances of a similar nature have come under my own observation. This, I think, will show the possibility of plants retaining variegation in their nature for many years, and only developing it when the plant has grown to a large size, or been subjected to some peculiar treatment.

Whatever may have been the origin of Lee's Variegated Scarlet, it is certain it was the parent of some of our very best silver-margined varieties. From it Mr. Kinghorn raised Flower of the Day, a variety which is still grown very largely, and is not yet surpassed for general usefulness by any at present in cultivation. Flower of the Day was followed by Mountain of Light, and a little later Mrs. Lennox appeared: after this Bijon, Alma, and many others in the same way. Previous to the appearance of these varieties Mr. Kinghorn raised Attraction, which was the first variety ever produced with a pink zone. This was followed by Countess of Warwick, and then the appearance of Mr. Elphinstone's varieties created a sensation. Their names were—Fontainbleau, Hotel de Cluny, St. Cloud, and The Queen's Favourite. In 1833 Mangles' Silver Variegated appeared as a sport on Pelargonium heterogamum in the garden of Captain Mangles at Sunning Hill. This variety has never been of any use for cross-breeding purposes. I have never known it ripen seed but once; that was at Oulton Park during the hot and dry summer of 1865. None of the seed vegetated. The origin of Golden Chain was a sport from P. inquinans, produced about the year 1844, in the neighbourhood of Ipswich. Some years after this Lady Plymouth also sported from P. graveolens. Osborne's Brilliant appeared in 1851; this was also a sport.

There are several claimants to the honour of having raised the first Tricolored Pelargonium. A correspondent stated in The Journal of Horticulture lately, that the first Tricolor was raised in the neighbourhood of Blackheath nearly twenty years ago, and that it was named Rainbow. If this statement is true, it is strange that a variety nearly equal to Mrs. Pollock should have remained unknown so long, and that its fortunate raiser had not a keener eye to business. Mr. Elphinstone, of the Sprowston Nurseries, Norwich, appears to have exhibited the first Tricolor. In a letter which I received from him some months ago, he said, "I raised the first Tricolor Pelargonium, and exhibited it at the Horticultural Society's rooms in Regent Street in the year 1851, and was highly complimented by the late Dr. Lindley." This variety Mr. Elphinstone sold to Mr. Veitch, who could do nothing with it, and eventually lost it. Major Trevor Clarke, I believe, was the first to discover the potency of the pollen of Golden Chain upon other varieties. To Mr. Grieve belongs the honour of having produced the first permanent Tricolor. His name will be handed down to posterity alone, as the originator of this beautiful class of plants. The advent of his Mrs. Pollock in 1861 caused quite a revolution amongst raisers and growers of bedding Pelargoniums. I have no doubt that Mr. Grieve procured Mr. Elphinstone's and Mr. Kinghorn's varieties, and with them was enabled to bring about such wonderful results. I know, from my own experience, that green seedlings from Mr. Elphinstone's varieties were produced in large numbers with very dark and partly variegated zones. The pollen of Golden Chain applied to the flowers of these would produce both Golden and Silver Tricolors. One of these seedlings, raised five years ago from The Queen's Favourite, I used last year as a female parent, because the zone was very dark and beautifully defined, and the plant showed faint signs of variegation on its stem. Its flowers were fertilised with the pollen of one of my Golden Tricolors: it has produced both Golden and Silver Tricolors, and one of the seedlings that remained perfectly green for nine months afterwards threw out both Silver and Golden Tricolors. This plant, also shown in my collection, is a living proof that both Golden and Silver Tricolors can be produced by one plant spontaneously.

I have noticed in many instances seedling plants producing a solitary variegated leaf after they had attained a height of 9 or 12 inches, and that this leaf has had sufficient power to inoculate the whole of the plant. If the variegated leaf is carefully preserved on the plant, and some of the green leaves above it are removed, the effect of inoculation will soon be observed. This will go on spreading and increasing until the whole system of the plant has become inoculated; the plant will then break out into variegation, and if any green leaves appear on the variegated sport they should be immediately removed. This will enable the variegated portions to predominate, and the future character of the plant will remain fixed and permanent, only occasionally, perhaps, showing a green leaf.

Again, small seedling-plants only showing very faint signs of variegation in the cotyledons will ultimately become permanently variegated, although no sign of variegation may be seen on any of the leaves of the plants for nine, twelve, or twenty-four months; afterwards, if such plants be kept, it will be seen on close examination by any one that there are streaks of variegation appearing on the stem near the position of one of the cotyledons. These streaks, if the plant be freely cultivated, will extend very rapidly, and the variegation will increase month after month until the whole system of the plant become thoroughly impregnated; then the plant will begin pushing out variegated shoots from the base upwards. Some-

times I have found the variegated portion extend too rapidly, especially when it begins to develope itself on very young plants or in an early stage of their growth. In this case, I always pinch portions of the variegated foliage away to enable the green leaves of the plant to recruit its strength, and when it is found necessary to check the predominance of the green part, portions of the foliage on this part of the plant are picked off. To such plants as these I give the preference. I have found, after the sports they produce are fixed, that they are propagated much more easily, and grow much more freely, than do the cuttings from plants that are perpetuated from seedlings which have become very much variegated in an early stage of their growth. In these, the constitution of the plant becomes very much crippled by variegation.

A curious instance of sporting is seen in a large plant of the bronze and gold section, named Her Majesty. The female parent of Her Majesty was one of the green seedlings from The Queen's Favourite, which I have before referred to. The plant was two years old when it was used as a pollen parent, and did not exhibit the slightest signs of variegation at the time I selected it for fertilising with the pollen of Beauty of Oulton, on account of its having a very deep zone. Two months ago it threw out a white sport near the position of one of the cotyledons. I took it off, struck it, and it is now to be seen in my collection. Another white sport appeared shortly afterwards; this still remains on the plant, and may be seen by any one who will examine the beautiful specimen named Her Majesty in my collection.

The preceding, I think, abundantly shows the way in which variegation is transmitted from one generation of plants to another; also that although it may not appear in the first, second, or third generation, it may in the fourth or fifth. This, I think, goes far to prove that variegation in plants is a disease.

In a future paper I will describe the results of some experiments I have now in hand. They will, I am sure, prove very interesting. I have inoculated some strong-growing plants with pieces of several kinds of both Golden and Silver Tricolor Pelargoniums. It will be curious to note what will be the result—whether they will be perpetuated singly or not by the plant, and what the effect on its flowers may be, and, above all, how the progeny will be affected.

I think I have stated enough to show that our old variegated Pelargoniums originated from sports, and that from them the numerous varieties now in cultivation have been perpetuated. I will now leave the subject to be dealt with by some of our scientific gentlemen, and hope they may be able to find out the causes of variegation.—J. Wills.

MILDEW ON ROSE TREES.

Though not a "rosarian," I am a lover of Roses, and in spite of deaths from last winter's frost, have considerably more than a thousand plants still flourishing.

The one enemy which I cannot subdue is mildew. It shows itself here and there at this time of year; but the time when it really works mischief is when the flower-buds are forming on the second growths early in August. Some varieties of the Rose are more affected by it than others. Prince Camille de Rohan, for instance, becomes with me so unsightly, and so debilitated by mildew, that I have half resolved to throw it out, although for hardiness in resisting low temperature, and for freedom in blooming, it is surpassed by none of its colour that I know of.

I notice that the Rev. Mr. Radclyffe recommends "vitriol" as an antidote to mildew and funguses in general. I have found the usual remedy, black sulphur, to be of inappreciable effect, and should be glad to try what Mr. Radclyffe recommends; but what is it? Sulphuric acid, sulphate of iron, and sulphate of copper, are respectively known as oil of vitriol, green vitriol, and blue vitriol.—Monticola.

[Either blue vitriol (sulphate of copper), or green vitriol (sulphate of iron), will do. You can purchase either of a druggist, who should pound it fine, and put it up in two-ounce packets. Two ounces are sufficient for a stable-bucketful of water. Before the vitriol is put into the cold water, it should be thoroughly dissolved in hot water, and well stirred when added to the cold water.

I never found any benefit arise from applying to the Rose mildew either yellow or black sulphur out of doors. If you would supply your plants with water, both over the leaves and at the roots in hot weather, you would not be so plagued with mildew. Mildew is called "the daughter of drought," because in such weather the leaves put forth sticky secretions, to which the sporules of the fungus adhere, and in due time take root, and spread with wonderful rapidity. As soon as you see the slightest "haze" on the leaves, or even before you see it, you had better pour the vitriolic lotion over those plants which are more liable (as some are) to fungoid diseases.—W. F. Radclyffe, *Okeford Fitzpaine*.]

THE LEAFING OF THE OAK AND THE ASH INDICATIVE OF THE SUMMER'S WEATHER.

Which comes into leaf first in the year? Is there any truth in the adage that if the Oak break leaf before the Ash it will be a wet summer, and if the latter show leaf before the Oak a dry one? In this neighbourhood the Oak is fully clothed and the Ash bare, and it usually is so—I think always so; but I have been contradicted in this saying by a person who professes to know.—Ashton-under-Lyne.

[The popular opinion in the midland counties is, that if the development of the leaves of the Oak precedes that of the Ash the weather during harvest will be fine; but that the weather will be wet if the Ash-leafing precedes that of the Oak. The rhymed form of the proverb is—

"If the Oak's before the Ash
Then you'll only get a splash;
If the Ash precedes the Oak
Then you may expect a soak."

The leafing of the Oak usually precedes that of the Ash.]

THE PARIS UNIVERSAL EXHIBITION.

I suppose that while very different views will be entertained of the Exhibition generally, there never has been and never can be but one opinion as to the building itself—that it is ugliness exemplified. People have compared it to a gasometer, &c.; but in truth it can be compared to nothing, for you can (unless you choose to mount the lighthouse, or some eminence), only see the exterior arcade. All the inner portion of the building, being lower, is of course hidden from view; and from its circular construction, as has been already oftentimes said, no vista, no lengthened view, can be obtained; while for the same reason the contents are shown off to the least possible advantage; yet withal it is a wonderful place. In the exterior portion, by courtesy called The Park, but really a vast conglomeration of every possible thing, lighthouses, churches, cafés, stables, farmyards, theatres, are brought together, and so completely cover the ground that all idea of a park is done away with. Therefore a contributor to The Journal of Horticulture has no excuse for dwelling on this portion of the undertaking.

Of the *jardin réservé*, however, we have a right to talk, and of this different opinions will also be entertained. It seems to me that the one predominating fault of the whole Exhibition has been that of forgetting the legitimate objects for which such gatherings were instituted, and, by attempting too much, spoiling the whole. What object, I may ask, can a Tunisian café or a Chinese theatre have in view so far as affording instruction and profit? And then in the horticultural department there are incongruities which ought not to have been tolerated, and which give a cocknified aspect to it. What legitimate object in connection with horticulture has a marine aquarium? and yet this grotto, stocked with sea anemones and fish, occupies a central position in the garden, and has been erected at the cost of some 300,000 francs. The mania for aquariums, which prevailed here some years ago, seems now to have seized the French; and in a prominent position on the Boulevards is now to be seen a large shop fitted up in a grotto, where you are invited to enter and see the animals fed at particular times, as the beasts at the Zoological Gardens. In the Jardin d'Acclimatation you find a whole house devoted to the same object; though what end is to be gained by acclimatising Crassicornis and Dianthus, &c., I am unable to say. I suppose it is this that has led to what I look upon as a great blemish. There may be some excuse for admitting Mr. Frank Buckland's salmon-breeding apparatus into the Royal Horticultural Society's gardens at Kensington, but why this grotto should have been admitted to the *jardin réservé* I know not.

We have been always so ready and willing to defer to the French in matters of taste, and to believe them to reign para-

mount there, that I think not a few persons will be surprised at the unmitigated bad taste of their large conservatory; while they will also smile, if they know aught about it, at the attempt at a flower show which it and the other buildings exhibited. The conservatory was half filled with Palms, grouped without any reference to good arrangement or beautiful effect. There was an attempt at grass, which was a miserable failure, while the grouping of the Azaleas was by no means first-rate. I am now alluding to what is called the fourth flower show; and we may well ask, Where is French horticulture? Take away the magnificent specimens sent by our zealous countrymen Messrs. Veitch, and the collections of the Belgian growers, and what would there be left? When I saw the Azaleas they had been some days exhibited, and were manifesting undoubted symptoms of flagging. The plants exhibited by the French and Belgian growers were very small—not equal to some of the third and fourth-rate collections of our International Show, and amongst the varieties exhibited there was nothing either new or of first-rate excellence. Amongst the new plants M. Linden, of Brussels, Messrs. Veitch, of Chelsea, and Mr. Bull, of Chelsea, were the principal exhibitors; and here again the French nurserymen were out of court. Collections of Agaves and Cacti filled some of the smaller houses; while in the grounds were some tolerably pretty beds of various kinds of annuals, plunged in pots and grouped together, mixed with Grasses, the prettiest bed being certainly a bed of Rhodanthe Manglesii surrounded with Collinsia, and that again bordered with Nemophila insignis. My good old friend, M. Margottin, had just planted a bed of standard Roses under canvas, and very pretty they looked, consisting as they did of many of our best kinds of all classes; but the plants were not large—nothing more, in fact, than the good ordinary-sized plants which are obtained from any respectable nurseryman. They had been grown under glass (but not forced), especially for the Exhibition. This reminds me that the Tea Rose sent out by Guillot fils last autumn, and called Madame Margottin, is really lovely. I have just bloomed it, and nothing can be more beautiful than the contrast between the outer delicate yellow petals and the lively peach-coloured centre.

Any one who remembers what the Champ de Mars was—who can call to mind, as I can, days when one has seen 80,000 troops and National Guards defiling before the Emperor, the ground resounding with the trampling of horses, the tread of men, and the roll of the artillery and waggon trains, but must feel astonished at its present aspect; and I hope I am not hypercritical in regarding the horticultural part as too trifling. It is very wonderful to see the petty lakes and the meandering rivulet; but, after all, the whole has rather a tea-garden aspect. Immeasurably superior was Mr. Gibson's grand result last year, even although produced under canvas, and consequently having to combat with the poles and framework, which were very likely to mar the effect, but which were lost sight of in the amazing blaze of beauty to be seen at all sides. I think, however, that we must pretty well come to the conclusion that international flower shows are only such in name. The perishable nature of the objects, the expense of transit, the certain loss of plants, make it almost impossible to expect the productions of foreign growers. But very few appeared at our International Show, and several of those would, I should think, never attempt it again. Messrs. Veitch and Mr. Bull are the sole representatives of English horticulture; and it is manifest that only a firm so wealthy and enterprising as the former could have sent such collections as they have done. I think one conclusion that every horticulturist may safely come to after a visit to the Paris Exhibition and the Paris nurseries is, that whatever the French may know concerning the theory of horticulture, yet in real love of plants and skill in growing them we are immeasurably beyond our neighbours. May I express a hope that some one will keep a sharp look-out on the new Roses, which were to be, I believe, exhibited on June 1st?—at least a letter from Guillot informed me that he and the other Lyons raisers were about to send their blooms up then; and there is one flower especially of his which I saw last year—a new hybrid Tea, of which I thought highly, and of which I should like to hear some well-qualified opinion. Unfortunately, my own visit was so planned this year, that I could not have the opportunity of seeing any of the new Roses. —D., *Deal.*

Viola cornuta.—Too much cannot be said in favour of this, either as a spring or autumn bedding plant. I have positively cartloads of it now in the highest state of perfection, being one perfect mass of flower; indeed, it is blooming so profusely that the flowers form a perfect sheet of bloom. As to the varieties, my opinion is well known to the readers of your Journal. I have just had a visit from Mr. Tillyard, who can bear witness to all I have said in its favour and as to its beauty.—Edward Bennett, *Osberton Hall, Worksop.*

ROYAL HORTICULTURAL SOCIETY'S GREAT SHOW.—June 4th.

This, which commenced on Tuesday last, and will continue open till Saturday, is the largest horticultural exhibition which has taken place since the International Show last year. It is held in the immense tent which the late Captain Fowke designed—that in which Messrs. Waterer & Godfrey's Rhododendrons were exhibited in former years; and though some of the large Ferns and fine-foliaged plants, too tall to place at the sides, obstruct the view of the smaller flowering specimens, still the general effect is very good, especially when the display is viewed from one end of the tent. Lofty tree Ferns, Yuccas, Dracænas, and noble Palms at once catch the eye and prevent that appearance of flatness which the more uniform height of the other plants would give; and the green turf banks on which the various subjects are arranged, afford a delightful relief to the eye from the bright and varied colours of the masses of flowers.

Azaleas are numerously shown, the principal exhibitors being Messrs. Penny, Wilkie, and Carson among amateurs, and Mrs. Glendinning & Sons and Mr. Turner among nurserymen. In the class for nine plants, Mr. Penny, gardener to H. Gibbs, Esq., is first with Brilliant, a very late variety, with an excellent constitution, producing vivid orange scarlet flowers of good shape and substance; Chelsoni, Sir C. Napier, Formosa, and Magnet, all different shades of orange scarlet; Magnificent and Iveryana, white; and Model, rose. Mr. Turner is second with plants mostly between 5 and 7 feet in height, and about 5 feet in diameter. Holfordi, Iveryana, and Gem are those in the best condition.

In the Nurserymen's class for six plants, Mrs. Glendinning & Sons take the first prize with the same plants as shown at the Royal Botanic Society's Show, and Mr. Turner is second with larger plants but not so healthy. In the Amateurs' class for six, Mr. Carson, gardener to W. R. G. Farmer, Esq., Cheam, was awarded a first prize for fine specimens of Apollo, orange scarlet, Symmetry, Stanleyana, Sir C. Napier, Variegata, and Model.

In class 4, fifteen plants in 12-inch pots, the best come from Messrs. Ivery, of Dorking, who have among others Madame Ambroise Verschaffelt, white flushed with salmon, and heavily spotted in the upper petals with deep red, a very fine and showy variety; President Claeys, salmon broadly edged with white, Charles Enke, Etoile de Gand, Gem, very bright in colour, Duchesse Adelaide de Nassau, scarlet blotched with violet crimson in the upper petals, very rich in colour; Leopold I., deep rose; Elegantissima, a fine white, flaked with carmine, but as shown too sportive in character, and Kinghorni, with large rosy lilac flowers. Mr. Turner has the second prize for a very good collection consisting of several of the preceding kinds, Brilliant, and President with large orange salmon flowers.

Roses form a most beautiful feature of the Exhibition; indeed, it is scarcely possible to speak too highly of the beauty of some of the specimen plants. Mr. Turner is first in the class for nine, with a splendid plant of Charles Lawson, and fine examples of Gloire de Dijon, Madame Boll, Général Jacqueminot, Souvenir d'un Ami, Vicomte Vigier, Queen, Juno, and Comtesse de Chabrillant. In the set of the same number from Mr. William Paul, who is second, are fine plants of Juno, Paul Perras, Souvenir d'un Ami, Niphetos, Senateur Vaisse, and Comte de Nanteuil. For six plants Messrs. Paul & Son are first with Charles Lawson, Juno, Souvenir d'un Ami, Celine Forestier, Lord Raglan, and Niphetos, all in excellent bloom. Messrs. Francis, of Hertford, who are second, have good examples of Madame Villermoz and Souvenir d'un Ami. In a miscellaneous collection from Mr. Turner, of Slough, the beautiful Alba Rosea, Souvenir de la Malmaison, and Beauty of Waltham are noticeable.

Of new Roses not sent out previous to 1864-5, there are only two collections, these being from Messrs. Paul & Son and Mr. William Paul, who each receive first prizes. The former have Michel Bonnet, a full rose-coloured flower, Duchesse de Caylus, Pierre Notting, very dark, Madame Victor Verdier, and Princess Mary of Cambridge; while Mr. W. Paul has, among others, Triomphe de la Terre des Roses, very large and full, violet rose; Jean Rosenkrantz, full, crimson; and Dr. Andry.

Pelargoniums are numerously exhibited, and with some exceptions in excellent condition. Mr. Turner, of Slough, has the first prize for nine, showing of light kinds Desdemona, Patroness, and Fairest of the Fair; Golden Hue, Lord Clyde, and Landseer, dark; Spotted Gem, Mdlle. Patti, and Lilacinum. Mr. Fraser is second with Caractacus, Sylph, Festus, Empress Eugénie, Sanspareil, Pericles, Mdlle. Patti, Lilacinum, and Rembrandt. For six, fine plants of Ariel, Rose Celestial, Lilacinum, Lord Clyde, Desdemona, and Leander, from Mr. Fraser, are first; and Mr. Turner is second with, among others, John Hoyle, a showy cloaded scarlet variety, with dark upper petals edged with carmine; Mary Hoyle, a very pretty orange salmon variety with a white centre and a rather small black blotch. Among

Amateurs, the best set of six is furnished by Mr. Nye, gardener to E. B. Foster, Esq., Clewer Manor, who has fine specimens of Mdlle. Patti, Etna, Desdemona, Belle of the Ball, Garibaldi, and Conqueror, which is larger than Lilacinum, but much the same in character. Mr. Ward, gardener to F. G. Wilkins, Esq., is second; Mr. Wiggins, gardener to W. Beck, Esq., third.

The Fancy varieties are always charming, and of these Mr. Fraser, who is first in the Nurserymen's class for six, sends beautiful examples of Ellen Beck, Roi des Fantaisies, Crystal Beauty, Lucy, Undine, and Celestial, the last very fine. Mr. Turner comes second with some of the varieties just named, Acme, and Ann Page. Mr. Bailey, gardener to T. Drake, Esq., Shardeloes, has the first prize in the Amateurs' class for good plants, though not so large as those which he has exhibited in former years. Mr. Weir, gardener to Mrs. Hodgson, Mr. Windsor, and Mr. Donald, Leyton, also exhibit.

A first prize for the best specimen Pelargonium of any kind is taken by Mr. Turner with Delicatum, a Fancy variety, measuring about 3 feet across, and quite a mass of bloom. Mr. Nye has a second prize for Rose Celestial (Show), about 3½ feet across, and admirably bloomed; and Mr. Fraser is equal second with Desdemona.

Mr. Turner also shows a miscellaneous collection of new Pelargoniums, among which The High Admiral, Charles Turner, and William Hoyle are remarkably fine varieties.

In the class for six Zonal Pelargoniums Mr. Fraser is the only exhibitor, taking a first prize for admirably grown and bloomed plants of Madame Werle, white, with a pink centre; Louis Rœseler, salmon scarlet, Rose Rendatler, Emile Lieau, orange salmon; Mousieur Rendatler, white, suffused with salmon; and Clipper, brilliant orange scarlet, very fine. We hope that at future exhibitions there will be several competitors, as it is evident that specimens such as those of Mr. Fraser are capable of adding much to the brilliancy and interest of horticultural gatherings.

Orchids are not so plentiful as they usually are at this season, nor are they so fine as we have seen them, but they comprehend a large number of interesting species. Mr. Penny shows the best collection of twelve; in this we noticed a fine specimen of Cypripedium barbatum, C. Hookeriæ with a dozen blooms, Vandas, Lælia purpurata, Dendrobium macrophyllum giganteum, D. nobile, Aërides Warneri, and Cattleya Warneri. Mr. Wiggins is second with a collection in which there are Saccolabium præmorsum with two fine racemes, Foxbrush and other Aërides, Cypripediums, Cattleyas, &c. In the Nurserymen's class for ten, Messrs. Veitch take the lead with Lælia purpurata, fine; Cattleya lobata, Mossiæ superba, and McMorlandii, the last with conspicuous orange markings in the lip; Cypripedium barbatum, and the bold-looking variety called Veitchii, Saccolabium guttatum, and other species. Mr. Williams, who comes second, has Cattleya citrina with a dozen blooms, Lælia elegans, the fine rosy purple and white Aërides crispum, and Oncidium altissimum. Mr. Bull is third, having among others Cypripedium caudatum with five flowers, several varieties of Cypripedium barbatum, and Cattleya citrina. In the class for six Orchids, Mr. Penny, who is first, has Saccolabium guttatum with five racemes, but short; and of Trichopilia crispa a fine specimen in beautiful bloom. Mr. Fairbairn, who is second, shows Vandas and good examples of other genera. In the Nurserymen's class for six, Messrs. Jackson, of Kingston, and J. & C. Lee, of Hammersmith, stand first and second, and exhibit a good example of Deudrobium densiflorum with orange blossoms, other species of the same genus, Odontoglossum citrosmum, Cattleyas, Lælias, and Vandas. For the best single specimen, Mr. Sherratt, gardener to J. Bateman, Esq., Knypersley, is first with Dendrobium MacCarthiæ; and Mr. Fairbairn second with Phalænopsis grandiflora, which is not, however, remarkable.

Stove and Greenhouse plants in flower are shown in great numbers and are generally fine. The principal exhibitors are Messrs. Lee, Rhodes, and Glendinning, among nurserymen; and of amateurs, Messrs. Wilkie, Carr, gardener to P. L. Hinds, Esq., and Peed. Among the plants shown are excellent specimens of Medinilla magnifica, Rhynchospermum jasminoides, Dracophyllum gracile, Allamandas, Stephanotis floribunda, Ixoras, Clerodendrons, Heaths, Azaleas, Genetyllis tulipifera, &c. The first prize in the class for the best specimen plant was awarded to Mrs. Glendinning & Sons, and the second to Mr. Wilkie, who both have Allamauda Hendersoni with immense blooms. Messrs. Lee are third with Dipladenia crassinoda.

Heaths are very numerously represented, and by fine specimens contributed by Messrs. Rhodes, Peed, Jackson & Son, Ward, and Wilkie; while beautifully bloomed plants in pots not exceeding 5 inches in diameter are shown by Messrs. Jackson and Osborn.

Of other subjects in bloom Mr. Wilkie has a fine standard Rhododendron; there are some Fuchsias, but not remarkable; and herbaceous Calceolarias are shown as usual in fine bloom by Mr. James, gardener to F. Watson, Esq., Isleworth. Mr. Williams contributes a dozen Amaryllises; and Mr. Turner takes a first prize and Mr. Bull a second prize for Lilium auratum, a plant of which from the former has a spike of ten blooms.

Fine-foliaged plants and Ferns are shown in great numbers, and most of the specimens are not only large but in beautiful condition. Pandanuses, Palms, Crotons, Dracænas; Alocasia metallica, Lowii, and macrorhiza variegata; Yuccas, Theophrastas, Gleichenias, Marattia elegans, Dicksonias, Cibotiums, Cyatheas, Alsophilas, and many others, are admirable. The collections sent by Mr. Williams, of Holloway; Mr. Fairbairn, Sion; Mr. Taylor, gardener to J. Yates, Esq.; Mr. Donald, Mr. Carr, Mr. Smith, Mr. Bull, and Messrs. Jackson, of Kingston, are well worthy of particular notice. Of Caladiums, likewise, there are some very fine plants from Mr. Fairbairn. For three Anthuriums, Messrs. Veitch have taken the first prize with A. Scherzerianum with four magnificent scarlet spathes about 5 inches in length, A. cordifolium or magnificum, and A. regale. Mr. Williams is second with the first named and A. magnificum, with its deep green leaves, prominently veined with pale green, measuring 2 feet in length and little less across. The third species is A. acaule with ample green foliage. In the class for the best pair of Yuccas or Beaucarneas, Mr. Williams takes a first prize with two very remarkable specimens of Beaucarnea recurva and B. glauca, Messrs. Veitch being second with fine specimens of the Variegated Aloe-leaved Yucca, and Mr. Bull third. Of Dracænas, Mr. Fairbairn shows a remarkably fine pair, but the species is not stated, and Mr. Williams takes a second prize with two fine examples of D. lineata. Agaves, from Messrs. Williams, Lee, and Bull, comprise some curious as well as pretty kinds. Of Pandanus Veitchii, Messrs. Veitch have a remarkable specimen forming an immense fan; and of tree Ferns, Mr. Williams shows a Dicksonia antarctica not less than 18 feet high, and Messrs. Veitch and Mr. Bull also show very large specimens of the same species. Chamærops humilis, of which Mr. Williams sent a very large specimen, was awarded the prize for the largest and finest Palm.

Of hardy evergreen trees and shrubs, interesting collections are shown by Messrs. Veitch, Bull, and Osborn; and Mr. Salter, of Hammersmith, has a very fine collection of hardy variegated plants, of which he possesses at his nursery a rich and curious collection. Of hardy British Ferns, Messrs. Ivery have a beautifully grown collection in which Athyrium Filix-fœmina Victoriæ, A. F.-f. plumosum, A. F.-f. pulcherrimum, and Polystichum angulare proliferum and plumosum are remarkable for their beauty. Mr. Salter and Mr. Bull also contribute many pretty forms.

Tricolor Pelargoniums are shown by Messrs. E. G. Henderson, Messrs. F. & A. Smith, Mr. Watson, and others, but these varieties have recently received so much attention that they need not here be particularised.

To some other subjects shown we shall have to revert next week; but Mr. Bull's singular Amorphophallus, referred to in the report of the Royal Botanic Society's Show, must be mentioned, as one of the most singular. It is now fully developed. Hottein japonica in group from Messrs. Veitch is also very fine. Mr. Fairbairn shows some fine Selaginellas, of which a panful of S. apoda is most beautiful. Mr. Bartlett, of Hammersmith, has also some fine Hymenophyllums.

Fruit is not one of the objects invited, but Mr. Ward, gardener to T. Miller, Esq., Bishop Stortford, has been awarded an extra prize for Pine Apples. He exhibits one Queen, weighing 5¼ lbs., and a Providence 8 lbs. in weight. Mr. Neale, gardener to R. A. Cartwright, Esq., Banbury, also has an extra prize for a very good Smooth-leaved Cayenne; and similar awards have been made to Mr. Tegg, gardener to the Duke of Newcastle, Clumber, for Brugnon Nectarines; to Mr. Sage, gardener to Earl Brownlow, Ashridge, for Peaches; to Mr. Sherrat, for Elruge Nectarines, and to Mr. Henderson, Cole Orton Hall, for a 14-lb. box of Black Hamburgh Grapes; besides which, he sends a collection of eight varieties. Mr. Fraser sends some very good Strawberries in pots, and to the Fruit Committee on the first day Mr. Rivers, of Sawbridgeworth, sent seven varieties of Cherries from pot trees, which being very fine were awarded a special certificate. Mr. Lydiard, of Batheaston, likewise sent a small collection of vegetables, and Mr. Francis, of Hertford, Hill's June Broccoli, a hardy sulphur-coloured variety.

Intending exhibitors will be glad to learn that they will now have an opportunity of examining the cups and some of the other prizes to be awarded at the Bury Show, these being placed on a table in the centre of the exhibition tent for public inspection.

At the General Meeting of the Society, held on Tuesday, W. Wilson Saunders, Esq., in the chair, twelve new members were elected.

Floral Committee, *June 4th.*—The seedling Show Pelargoniums were the great feature of this meeting. There were many entries for these, and but little novelty among them. Probably the fickle weather we have had of late may have affected them, for in many instances the petals were crumpled and the flowers were deficient in smoothness and outline. Mr. W. Nye, gardener to E. B. Foster, Esq., exhibited several seedlings. First-class certificates were awarded to Rob Roy, Joan of Arc, and The Emperor. This last was considered the flower of the year, it was most superb. Messrs. Downie, Laird, & Laing, sent a collection of Zonal, Nosegay, and other varieties. A fine, broad-petalled, bright rose, intermediate variety, Seraph Zonal, was awarded a first-class certificate. There were many promising varieties, but in this and other instances the plants were too young and small to give any idea of their qualities, and unless the Nosegay section is seen planted out or in a mass, it is generally impossible to come to the merits of the plant. The bedding Pansy, Imperial Blue, sent out by Messrs. Downie & Co., seems to be a useful variety.

Messrs. Backhouse received a first-class certificate for Silene pennsylvanica, a dwarf plant, covered with bright pink flowers, and very useful for rockwork and other decorative purposes. Mr. Hoyle, Reading, exhibited eleven seedling Show Pelargoniums; Example and Victor, had received first-class certificates last month. There ap-

peared too great a similarity among them, and no advance on last year's seedlings. Mr. Turner, Slough, received a second-class certificate for a very pretty Fancy Pelargonium Madame Vilda, a very deep carmine flower with a pure white centre. This plant will improve upon acquaintance and become a favourite. Mr. Wiggins sent nine seedling Show Pelargoniums—Hermit was awarded a first-class certificate, Filomena a second-class certificate. The gardener to J. R. Ramhill, Esq., Walthamstow, sent three promising Zonal Pelargoniums, but the plants were too small to justify any award. Messrs. Ivery received first-class certificates for Polystichum angulare oxyphyllum, Athyrium Filix-fœmina plumosum multifidum, the Axminster variety of A. Filix-fœmina plumosum, and A. Filix-fœmina Girdlestonii. Mr. Watson exhibited again his Nosegay Pelargonium Excelsior, which is not sufficiently distinct from other varieties. Messrs. Salter, Versailles Nursery, were awarded a first-class certificate for a beautiful variegated plant, Coprosma Baueriana variegata. Mr. Robert Veitch, Exeter, sent two magnificent specimens of Adiantum Farleyense and Adiantum species, probably a seedling from the former. Mr. Stone, gardener to J. Day, Esq., exhibited a new and very magnificent variety of Cypripedium Stonei, with much broader petals and stripes in the wings—a decided improvement on C. Stonei. It received a first-class certificate. He also exhibited Cattleya Dawii, a superb plant, which had received a first-class; Epidendrum vitellinum majus; and Oncidium Krameriannm, but which was said to be O. papilio pictum. Messrs. E. G. Henderson sent a large group of interesting plants very prettily arranged, edged with a double row of their Pyrethrum aureum, or Golden Feather. A special certificate was awarded. Mr. D. Ferguson, Whitton, Hounslow, sent a collection of Petunias; Mr. W. Paul, Nosegay Pelargoniums Blue Bell, Crimson Queen, Little Gem, all of which have been noticed before.

Mr. James Clarke, Bury St. Edmunds, sent a very singular seedling Pink, a deep rose colour, fine smooth petals. It came without a name; the Committee named it Clarke's Rose Pink, and awarded it a second-class certificate. It is a very pretty and useful variety. A short history of its origin would be very interesting. Mr. Munn, Brentwood, sent some very pretty seedling Zonal Pelargoniums. First-class certificates were awarded to Mimas, a beautiful light orange scarlet, a fine-formed flower; Rosabel was a distinct colour, but rough, as exhibited on Tuesday. Messrs. F. & A. Smith, Dulwich, exhibited two collections of Zonals, the one with plain foliage, the other consisting of some of their best Versicolors or Tricolors. This collection was not entered for the examination of the Committee, and consequently the various seedlings in it received no award. Among the twenty sent, L'Empereur, Louisa Smith, Impératrice Eugénie, Queen Victoria, Meteor, and Prince of Wales appeared to be plants of great merit, and will please all who may be desirous of purchasing them. Mr. Bull sent Zonal Pelargonium Valiant, Petunia Official, a striped variety, Pyrethrum aureum, and Lobelia Rosy Gem.

Weekly Show, *June* 1*st*.—Prizes were offered for collections of French Pelargoniums (amateurs), Orchids, miscellaneous plants (open), and for the best exhibition of fruit. Mr. A. Wilkie, gardener, Oak Lodge, Addison Road, Kensington, was awarded a second prize for Pelargoniums, and also a first prize for collection of miscellaneous plants; an extra prize was also awarded Mr. Wilkie for a collection of Ferns and Heaths. A third prize was obtained by Mr. W. Bartlett, Shafteshury Road, Hammersmith, for Pelargoniums, and an extra prize for collection of Maiden-hair Ferns. Mr. Bartlett exhibited a collection of miscellaneous plants, and also a collection of hardy Ferns. An extra prize was awarded Mr. Niell, Rivington, Lancashire, for a box of seedling Calceolaria blooms; and Mr. W. Earley, gardener to F. Pryor, Esq., Digswell, Welwyn, Herts, gained an extra prize for a collection of vegetables. From the Society's garden, at Chiswick, an interesting collection was exhibited of Gloxinias, Calceolarias, Petunias, Sedum variegatum, &c.

ACCLIMATISATION OF NEW ZEALAND TREE FERNS.

The hardihood of two or three species of the New Zealand tree Ferns has been rather severely tested at Kilronan, Co. Roscommon, the beautiful residence of Colonel and Lady Louisa Tenison. We say severely tested, for there did not appear to be any special precautions taken in their favour when placed ont of doors. They must have had goodly stems, inasmuch as her ladyship had received them from a friend, direct from New Zealand, some years previously, and it was their having outgrown their house accommodation at Kilronan that suggested the idea, and was the immediate cause of subjecting them to the ordeal. It appears they had done famously, and, as may be imagined, formed charming objects out of doors through the summer, and continued to be such up to Christmas, when they were actually putting forth from their crowns a new growth of their crosier-like fronds, and their pushing at that season formed one of the most serious grounds of apprehension for their safety; for though up to that period "the mildness of the season was in everybody's mouth," a change might suddenly come, and not alone rudely check this unseasonable development of fronds, but do for the plants altogether. Well, a change did come, and with a vengeance, too! A Christmas-eve and a Christmas-day mild and warm almost to oppressiveness; a New Year's-day of bitter cold and snow, the former increasing in intensity until but four days later the mercury on the other side of the Irish Channel fell below zero, and here (Ireland) it was not many degrees above it.

We anxiously, but almost hopelessly, looked for tidings of the tree Ferns at Kilronan. We should have previously mentioned that the kinds subjected to exposure were Cyathea medullaris, a noble Fern, and further remarkable as the one whose pith, formed a staple article of food of the Maori, and C. dealbata the most light and airy, as well as, perhaps, the loftiest, of the New Zealand tree Ferns, its stems often reaching the height of 40 or more feet. In the course of this week Dr. de Ricci placed in our hands a portion of a frond of the latter, received from Lady Louisa Tenison, and which she had just taken from the specimen of C. dealbata that had been exposed to the Siberian rigours of the past winter, and had come through entirely unscathed. It appears, in fact, it was the plant that had not a shadow of protection that is now in such fine condition. The portion of frond lying before us is as fresh-looking as possible, and not even in the least browned or discoloured, and we are informed the young growths above alluded to are coming away quite uninjured. On the other hand, C. medullaris succumbed to the severity, and is gone. That Kilronan this year did not enjoy any special immunity from very severe frosts may be inferred from the fact that its beautiful lake was frozen to the depth of several inches, and traversed as a roadway by the people.—(*Irish Farmer's Gazette.*)

INTERNATIONAL HORTICULTURAL EXHIBITION OF 1866.

It is gratifying to be able to announce the highly satisfactory conclusion to the Great Horticultural Exhibition of 1866. In the correspondence which follows, the arrangements which the Executive Committee have finally made will, we doubt not, meet with the approval of all who are interested in the advancement of horticultural and botanical knowledge, by the establishment of what will henceforth be known as "the Lindley Library." Since the dispersion of the rich library the Royal Horticultural Society formerly possessed, there has been no place where the horticulturist could go for reference to works that are not in everyday use; and from the central position at Sonth Kensington, and the facilities that will be afforded to readers, the Lindley Library must become a great boon to all who would desire to make use of the advantanges it offers.

"Botanic Gardens, Chelsea, April 11, 1867.

"Sir,—I am desired by the Executive Committee of the International Horticultural Exhibition, to forward you the enclosed copy of certain proposals for the disposal of the surplus funds now in its hands, adopted at its last meeting, and through which it is trusted the Society will derive some permanent benefit in acknowledgment of the facilities granted by your Council to the Committee at the time the extension of the Great Show was thonght desirable.

"May I beg that you will lay the proposals before the Council at the earliest opportunity, and that you will as soon as possible acquaint me with its reply? "I am Sir, your obedient servant,

"Thomas Moore.

"To the Secretary of the Royal Horticultural Society."

Extract from Minutes of Executive Committee, Embodying the Proposals above Referred to.

"1, That the surplus funds realised at the International Horticultural Exhibition of 1866, be applied to the establishment of a permanent horticultural and botanical library, to be vested in seven Trustees, as hereinafter mentioned, and to be called The Lindley Library, in memory of the late Dr. Lindley and his zealous devotion to the cause of horticultural and botanical science.

"2, £600 of this surplus to be applied to the purchase of Dr. Lindley's own library. As it appears that the Royal Horticultural Society has already provisionally secured possession of this collection with a view to prevent its dispersion, the Society to surrender it to the Trustees absolutely, in consideration of being repaid the sum of £600 in question.

"3, The Society to consent to the Library now proposed to be formed, being placed in the Council-room during the period of the continuance of their lease under the Royal Commissioners for the Exhibition of 1851.

"4, Of the balance of the fund (about £1200), the Trustees to expend such sum as they may think expedient in the purchase or construction

of bookcases and fittings for the reception of the Lindley Library, and any subsequent extension of it in the Council-room of the Society.

"5, The Library to be available for consultation by Fellows, Members, and Associates of the Royal Horticultural Society, and other persons possessing rights of admission to the premises; also, by gardeners on their producing a satisfactory introduction from their employers, and by young gardeners who may have passed or are preparing for the examinations held by the Royal Horticultural Society and by the Society of Arts. In the case of other persons to whom it may appear desirable to give the privilege of consulting the Library, the Trustees and the Society to agree upon the conditions under which the privilege of admission shall be given.

"6, In the event of the books being kept under lock and key in the bookcases, the Society to entrust the custody of the keys to one of its officers, who shall be prepared at all reasonable times to give access to the books to those persons entitled to consult them.

"7, The remaining balance of the surplus, after providing for the above items of expenditure, and setting aside any sum that may be necessary for contingencies (such as the preparation of the trust deed hereafter referred to, &c.), to be applied by the Trustees to the purchase of further works to be added to the Library.

"8, A trust deed to be prepared for the purpose of giving effect to the present arrangement,—three of the Trustees to be appointed by the International Executive Committee (namely, the three Secretaries of the International Horticultural Exhibition and Botanical Congress, Mr. Thomas Moore, Dr. M. T. Masters, and Dr. R. Hogg), three by the Royal Horticultural Society (namely, the Treasurer and Secretary of the Royal Horticultural Society for the time being, and one other person to be chosen by the Society), and one to be added by the six Trustees above-mentioned jointly.

"9. The Trustees to have the power of removing the whole of the books purchased under the trust, or added to the Library by presentation, together with all the bookcases, fittings, &c., referred to in paragraph 4, in the event of the determination of the lease held by the Society under the Royal Commissioners, and of making such arrangements as they may think fit for establishing the Library elsewhere."

"Royal Horticultural Society, South Kensington,
"April 17, 1867.

"Sir,—The extract from the minutes of the Executive Committee of the International Horticultural Exhibition respecting their surplus, which you were good enough to forward me, was yesterday read to the Council, and I am requested to convey to you their thanks for the very liberal proposition which your Committee has made.

"The Council will, as wished, surrender absolutely the Lindley Library for the sum of £600; and in accordance with the terms of paragraph 8 has elected Mr. W. Wilson Saunders as the third and permanent Trustee from the Council.

"With respect to paragraph 5, the Council would prefer that the admission of strangers should be regulated by the Trustees, and perhaps your Committee will find no difficulty in adding this slight concession to their very handsome present.

"The Council desire me to add that in their opinion no better or more acceptable return could have been made to the Society for the facilities afforded to your Committee by the Council.

"I have the honour to be, Sir, your obedient servant,
"Henry Scott, Secretary.

"To Thos. Moore, Esq., F.L.S., &c.

ROYAL BOTANIC SOCIETY'S SHOW.

May 29th.

A short account of this Exhibition having been given last week, it now only remains for us to notice more particularly the principal subjects which collectively produced one of the most effective displays ever seen at the Regent's Park, but at which, unfortunately, there was not so large an attendance of visitors as usual, owing to the occurrence of a thunderstorm in the forenoon and of frequent heavy showers in the afternoon.

Of stove and greenhouse plants, collections of ten were furnished by Messrs. Baines, Peed, Kemp, and Wheeler, who had prizes in the order in which their names are mentioned. In Mr. Baines's collection several of the plants which he had at the Crystal Palace Show were reproduced in excellent condition, especially his fine Acrophyllum venosum and Genetyllis tulipifera. Mr. Peed's Acrophyllum, though not so large, was in fine condition, showing the rich reddish brown young leaves at the ends of the flower-spikes, as the plant should do when in perfection; his Allamanda grandiflora had much improved, and was a mass of large yellow flowers. In other collections, besides the species already named, were Statice profusa, Leschenaultia biloba, fine examples of Stephanotis floribunda, Azaleas, Heaths, Rhynchospermum jasminoides, Dracophyllum gracile, Eriostemons, Clerodendrons, Aphelexis, Tetratheca verticillata, a magnificent example of Medinilla magnifica (from Mr. Wilkie, Mr. McHenry's gardener), and many other plants which have frequently been noticed at similar exhibitions.

Collections of eight were furnished by Messrs. Donald, Coles, and Wilkie, among amateurs, and by Messrs. Lee, Rhodes, Glendinning, and Williams, among nurserymen, each of whom took prizes in the order in which their names are stated; whilst collections of six came from Mr. Ward, Leyton, and Mr. Smith, Norwood.

Of fine-foliaged plants alone and mixed with flowering specimens effective groups were furnished by Messrs. Lee, Williams, Fairbairn, Baines, Glendinning, Donald, Rhodes, Peed, Kemp, Ward, and Wheeler, and included tree and other Ferns, Palms, Cycads, Rhopalas, Dracænas, Cordyline invidisa, Aloe-leaved Yucca, Beaucarneas, Alocasias, Sarracenia purpurea, variegated New Zealand Flax, Dieffenbachias, &c.

Ferns, too, were represented by fine collections from Messrs. Williams, Taylor, and Baines, comprising many beautiful specimens, among which were Lomaria gibba and cycadiflora, Cyatheas, Cibotiums, Dicksonias, Davallias, Todeas, and Nothochlæna lævis. Messrs. Ivery, of Dorking, had a pretty collection of British Ferns, of which Athyrium Filix-fœmina Girdlestonii, the Axminster variety of A. F.-f. plumosum, and Athyrium angulare oxyphyllum had first-class certificates.

Of Roses there was a very fine display. Mr. Turner, of Slough, whose plants at the Crystal Palace were not quite far enough advanced, had them now in perfection, they being covered with magnificent blooms, and in growth and foliage all that could be desired. The varieties were Anna Alexieff, Charles Lawson, of the largest size, Vicomte Vigier, Maréchal Vaillant, Victor Verdier, Souvenir d'un Ami, Celine Forestier, Baronne Prevost, Général Jacqueminot, and Souvenir de la Malmaison. Mr. William Paul, who was second, closely pressed Mr. Turner with remarkably fine plants of Lælia, Charles Lawson, Juno, Paul Ricaut, Général Jacqueminot, Madame Villermoz, Souvenir d'un Ami, and President. Messrs. Paul and Son, who were third, had fine plants of Madame de St. Joseph, Celine Forestier, and Charles Lawson; and Messrs. Francis, of Hertford, and Mr. Terry, Youngsbury, Ware, had also good groups. Beautiful cut blooms were likewise furnished by Messrs. Paul and Sons.

Orchids, though not so numerous and fine as at the corresponding show last year, comprised, nevertheless, some very fine specimens, the most remarkable of which was the Cypripedium caudatum, noticed last week, and shown in the collection of fifteen from Mr. Wilson, gardener to W. Marshall, Esq., Enfield. This had a dozen very large blossoms, with tails about 2½ feet in length. Odontoglossum Alexandræ from the same exhibitor was also very fine. The second prize was awarded to this collection, the first prize going to Mr. Penny, gardener to H. H. Gibbs, Esq., who had Aërides Warneri, and others of the same genus, a fine specimen of Calanthe veratrifolia, Odontoglossum Phalænopsis, Dendrobium Parishii, Cypripedium lævigatum, Lælia purpurata, Lycaste Skinneri, and other well-known species. Mr. Gedney, gardener to the Rev. W. Ellis, was third. Mr. Peed had a finely-flowered plant of Oncidium sessile, a species which was also shown in good bloom by Mr. Fairbairn, of Sion. For eight plants, Mr. I. Hill, gardener to R. Hanbury, Esq., The Poles, Ware, was first with, among others, good examples of Vanda suavis and tricolor, Calanthe veratrifolia, Chysis Limminghi, Phalænopsis grandiflora, Cattleya Skinneri, and Cypripedium Stonei, the last a fine species, but as yet by no means common. The second prize was taken by Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, who contributed Saccolabium præmorsum, Dendrobium densiflorum, Cypripedium hirsutissimum, and other well-managed plants. Messrs. Veitch received a first prize for a collection of six plants, among which were Cattleya Mossiæ superba and lobata, Cypripedium barbatum, Lælia purpurata, and the Fox-brush Aërides, beautifully flowered. From Mr. Young, Leigh Park, came Phalænopsis Schilleriana, in good condition; and Mr. Williams, Messrs. Lee, and Mr. Bull likewise contributed collections of Orchids.

Azaleas constituted a brilliant feature of the display, but many of the specimens were scarcely so fine as in former years. The first prize for eight was awarded to Mrs. Glendinning & Sons, for well-grown pyramidal plants, well covered with bloom, and displaying here and there green leaves with excellent effect. The sorts were—Gem, Alba lutescens, white striped with red; Madame Miellez, Variegata, Perryana, Extrani, Eulalie, and Iveryana. Mr. Turner was second with plants which, as regards size and beauty, have for these last few seasons been the admiration of all who have seen them, but which, though very effective, were greatly past their best as regards constitution. In the Class for six Azaleas, Mr. Turner was first with magnificent examples of Juliana, Petuniæflora, Holfordi, Sir Charles Napier, Iveryana, and Flower of the Day.

Of Cape Heaths there was a fine display, furnished by Messrs. Rhodes, Peed, Baxendine, Kemp, and Ward. The best came from Mr. Rhodes.

Pelargoniums, as usual, at this Show were very beautiful, being even finer than at the Crystal Palace on the previous Saturday. In the Class for nine plants equal first prizes were awarded to Mr. Turner and Mr. Fraser. The former had fine plants of Lilacinum, Pericles, Spotted Gem, Royal Albert, Patroness, Fair Rosamond, Belle of the Ball, Desdemona, and Lord Clyde; and Mr. Fraser Rose Celestial, Empress Eugénie, and others. In the Amateurs' Class, Mr. Nye, gardener to E. Foster, Esq., had the best collection, in which were Sir Colin Campbell, Desdemona, Patroness, Belle of the Ball, Garibaldi, Etna, Mdlle. Patti, Rose Celestial, and Fair Rosamond. Mr. Ward, Mr. Wiggins, and Mr. Weir, also showed collections in this class. In Fancy kinds Mr. Fraser was first with very fine examples of Lucy, Celestial, Clara Novello, Roi des Fantasies, Arabella Goddard, and Maroon. Mr. Turner, who was second, had Delicatum, Lady Craven, Godfrey Turner, and others, in nearly equally good condition. Mr.

Donald, Mr. Weir, and Mr. James, also showed pretty collections of Fancy kinds.

New Plants were very numerously shown by Messrs. Veitch, Bull, Williams, E. G. Henderson, and others, as may be judged from the fact that some ninety certificates were awarded for them; but they have nearly all been noticed in previous reports. Amorphophallus nobilis, exhibited by Mr. Bull, deserves, however, special mention, on account of its singular-looking flower, which was in course of development, and which formed a fleshy mass about 7 inches in height, and 4 or 5 inches in diameter, and was of a deep chocolate colour becoming paler towards the base. Like most of the genus the flower will probably have a very offensive odour when fully developed. From Mr. Wilson, garden to W. Marshall, Esq., came a pretty variety of Miltonia spectabilis, called rosea, and from J. Gray, Esq., Ashridge Park, a variegated form of Deutzia gracilis.

First-class certificates were awarded for the following new Show Pelargoniums—viz., Man of Mark, Example, and Victor, raised by Mr. Hoyle, of Reading, and exhibited by Mr. Turner; to Hermit and Lady of Quality Improved from Mr. Wiggins; and to Grandee, Rob Roy, and Emperor from Mr. Nye, gardener to E. Foster, Esq., Clewer. Certificates of the same class were also given for Marmion, Pink of Perfection, and East Lynn, three Fancy varieties, shown by Mr. Turner. Of Nosegay varieties Emmeline, from Messrs. Downie, Laird, & Laing, and Dr. Hogg and Waltham Nosegay, from Mr. William Paul, had first-class certificates, and a similar award was made for Lord Derby, a Zonal variety, shown by Mr. Mann, of Brentwood, and noticed at page 373.

Of other subjects, Messrs. Downie, Laird, & Laing had a very good stand of cut Pansies, and good blooms were likewise exhibited by Mr. Hooper, Bath, Mr. Kingston, and Mr. James, of Isleworth, who had also some fine herbaceous Calceolarias. A pretty group of flowering and fine-foliaged plants, edged with the silvery-leaved Meadow Grass and Golden Feverfew, came from Messrs. E. G. Henderson; some beautiful Aucubas and other variegated hardy plants, as well as some very fine standard variegated Pelargoniums, from Mr. W. Paul; Lilium auratum, from Mr. Turner and Mr. Bull; Anæctochilus, from Mrs. Glendinning & Sons; a fine pair of Agave filifera, from Mr. Bull; a large and handsome specimen of Iresine Herbstii, from Mr. Hill, gardener to R. Hanbury, Esq.; a magnificent group of Sarracenias, from Mr. Baines; cut flowers of Ixias and other Cape bulbs, from Messrs. Hooper; and variegated Bamboo and other plants, from Messrs. Barr and Sugden.

ENTOMOLOGICAL SOCIETY'S MEETING.

The May meeting, held on the 6th ult., was presided over by Professor Westwood, V.P. Amongst the donations to the Society's library received since the last meeting were several works of considerable interest—namely, M. Snellen Van Vollenhoven's two volumes on the insects of the Dutch settlements in the Spice Islands, belonging to the families Scutelleridæ (Hemiptera), and Pieridæ (Lepidoptera Diurna); and Mr. Stainton's volume on the Tineina of the Holy Land; and the tenth volume, completing the first series, of his great work on the Tineina of England, a second series of ten volumes being announced. Some valuable works by Dr. J. Leconte on the Coleoptera of the United States of America were also presented by their author. A new part of the Society's "Transactions" was announced as ready for distribution among the members.

Mr. Bates read a communication from Dr. Felder, of Vienna, in which he made some observations on the priority in date of publication of some of the species of Butterflies contained in the volumes of the Novara expedition. He also made some very severe comments on Mr. F. Walker's catalogues of Lepidopterous insects published by the Trustees of the British Museum.

Mr. Stainton exhibited some larva-cases of Coleophora lexella, which has the remarkable habit of feeding when in the young state of the larva on Thymus serpyllum, but at a later period it transfers itself to a species of grass. This species had been forwarded to him by Herr Heinemann, of Brunswick. He also exhibited the larva of Hyponomeuta egregiella first found in the south of Spain, and afterwards at Cannes by Mr. Millière, and at Fontainbleau by Mr. Stainton feeding on Erica cinerea. The specimen was then engaged in spinning its cocoon.

Professor Westwood mentioned that he had recently received some Cimicidæ (Enicocephalus Tasmanicus), from New South Wales, which congregate in the air like Ephemeræ, and emit a pleasant scent like musk, which had communicated itself even to the letter in which the insects had been forwarded.

A communication from Mr. Fereday, corresponding member in New Zealand, was read, mentioning the capture of Cynthia Cardui in that colony. Mr. Bates, however, stated that it was the Australian form of the species, differing permanently from the European one, and likewise that the so-called C. Cardui of South America was a pink variety of C. Huntera.

A letter was read from Mr. C. A. Wilson, corresponding member at Adelaide, in which the writer gave an account of a Centipede having been killed by the excessive heat (114° to 116°), in Cockatoo Valley. He also announced the discovery, on the banks of the Gawler River, of a species of Strepsiptera, by Mrs. Kreusler, being the first instance of that order being detected in Australia. Mr. F. Smith added some further information respecting this parasite, and exhibited specimens of the Wasp Paragta decipiens, in the body of which it is parasitical. It was also stated that Mr. Holiday had noticed the genus Stizus to be infested with these parasites in Italy.

A paper by Mr. H. W. Bates was read, on a collection of Butterflies formed by Thomas Belt, Esq., at the mines of Montes Aureas, in the interior of the province of Maranham, about 160 miles south-east of Para. During three months Mr. Belt had collected not fewer than 364 species of Butterflies, amongst which eight were new to science.

Mr. S. Stevens exhibited some very interesting Carabidæ, collected by Herr Darnell in the district of Cape York, on the north coast of New Holland.

ALKALINE SALTS AS MANURE FOR POTATOES —FEATHER-STEMMED SAVOY.

Last year I intended proving the utility of alkaline salts as manure for Potatoes, but circumstances prevented my carrying out the experiment as I wished. I had about three roods of ground for the purpose, and planted eight varieties of Potatoes, using the salts on each alternate row of all the varieties, so that there could be no difference in the soil. There was scarcely any difference in the appearance of the small-topped sorts, such as Daintree's and Handsworth; but the stronger-growing varieties, such as Fairbairn's Pink Seedling, Ambassador, and King grew remarkably strong in the haulm, the colour being of the darkest green. The tubers of the rather late varieties grew again before being ripe much more than those not treated with the manures referred to. As to flavour, mealiness, &c., I fear the good effects of alkaline salts are all a myth. It is very probable, I think, that alkalies may be advantageously used in growing early varieties; but as regards the general crop of Potatoes, they do not return a tithe of the expense. This is not my first acquaintance with saltpetre, &c., as manure.

My limited experience leads to the following conclusions:—Alkaline salts are good for Trefoils and Grasses generally; in fact, wherever foliage is the main object of the cultivator. With cereals they grow large crops of straw at the expense of the grain. I shall at some time try their effects as hurrying manures for early crops, and when I can state the results with scientific accuracy I will send you an account.

I also wish to call the attention of your readers to a vegetable which is not grown so extensively as it deserves to be; I refer to the Feather-stemmed Savoy. It has a rather coarse appearance during the autumn and early winter months, but after the heads have been cut the stems continue to throw an abundance of sprouts, which when cooked are exceedingly tender and well-flavoured. It is so hardy that the severe weather last winter had very little effect upon it, although Kale, Brussels Sprouts, and Roseberry Sprouts were very much destroyed.—F. Flitton.

ORCHARD-HOUSE MANAGEMENT.

In reply to the request of "Subscriber," page 347, I must first say that I merely threw out the hint respecting orchard-houses for the Editors of the Journal to take up, not at all expecting my letter to be published in full. I feel quite unable to advise others, being myself only a learner; but as far as I can I will offer such explanations as "Subscriber" asks for.

I have roughly measured my ground, and find that I have in lawn 1400 yards, in kitchen garden and frame ground about one acre, and the remainder in carriage-drive and shrubbery. I turn out this year seven hundred pots of flowers. I work ten lights of frames. I have an orchard-house 42 feet long by 14 feet wide, a vinery 12 feet by 9, a Fig-house 12 feet by 9, a Cucumber-house 18 feet by 6, and a Mushroom-house 18 feet by 5.

I think that in gardens of ordinary size like mine, where no skilled gardener is kept, much labour may be saved by carefully attending to a few points like these.

First, let the master who intends to help in any way really do the work he attempts. I never call a man from his work to bring me this or that. I take the tools, ladder, &c., which I may want, and thus my help is really of service.

Secondly, I always have help when it is really wanted, and thus the work is done at the proper time. In hot weather, for example, I have every weed cut down: an extra man is worth much then, and will save labour for weeks afterwards.

Thirdly, I save labour by having plenty of room for putting things into their right place. For example, I have room in my frame ground for the manure to lie ready for the beds. I

have often seen three men at work at a hotbed, two filling and wheeling from the heap 20 or 30 yards off, and one making the bed. My plan is to have the manure drawn to the garden door, have it wheeled in and shaken up on a day when no other work presses, and then when the hotbed is to be made it requires one man only, and he will do it in a very short time. I also have pits 2 feet deep for my beds. This saves much time in measuring the ground and in making up the bed; and much less skill is requisite, as anybody can raise a bed 2 feet high, which is quite sufficient above the ground line.

Fourthly, I have all work done in winter that can be done. The whole garden is dug and manured in winter, and thus the cropping is far less laborious. I have seen crops of Peas ready to stick, when the man has had to take a horse and cart to bring the sticks, and then to spend a day in cutting and sharpening them, and then to carry them to the Peas. I have such work done in the winter, and the sticks stacked close to the ground intended for Peas.

These are just examples of the many trifles in which I think labour in small gardens may be well or ill applied.

My own help is not great, as I have much work on my hands. I am a country clergyman with a wide parish and a large school, and my time is, of course, very much taken up; but I manage every morning to go round my garden and give directions for the day's work, and in the evening I can often do a little nailing or pruning.

I have omitted to state that I think it great economy to have plenty of tools, water-pots, wheelbarrows, and every working requisite.

If "Subscriber" really thinks of putting up an orchard-house, and would like to see mine, I hope he will let me know his nearest railway station; and if within distance of me I hope he will come for the day, when he shall know all my secrets if I have any to communicate. Most probably he is already far in advance of me in gardening knowledge.

I would just add, that while I of course look up to Mr. Rivers as the father of the orchard-house system, and doubt not that in his soil and climate his rules are perfect, I think they require considerable modification in other soils and climates. I cultivate my trees with considerably less trouble than his rules advise. This is my fourth year, and I have departed more and more from his rules each year with manifest advantage, and this year I am perfectly satisfied. I do not see many orchard-houses to compare them with my own, but I cannot imagine one nearer perfection. I have forty-nine trees in it, of which one is blank, three have small crops, and the remainder are really pictures—full of fine fruit now, numbers of them 3 inches in circumference—not a vestige of insect or curl, except here and there a little scale, which springs into being after the tree seemed quite free—in a single day apparently; but you may look a good while before you find one of these.

I ought to add that I have 100 yards in length of wall, covered with fruit trees, varying in height from 7 to 12 feet. —C P.

POOLEY'S TOBACCO POWDER.

In my article on this insect-killer in your last number I find it stated that this powder should be applied before the dew was "on" the leaves and insects; it should be before the dew is "off," since it is the dew, impregnated with tobacco dust, which kills the insects. Since I last wrote on this subject I have tried various other experiments with the powder, all of which were most satisfactory. Another person, to whom I gave some of the powder, used it on a Honeysuckle completely covered with aphides. On my inspecting it the day afterwards I found all the insects dead.—Observer.

[We have inserted this and the preceding communication having faith in an old subscriber who is known to us; but we are not surprised at having a letter, from which the following is an extract:—

"What are we to infer from the statement of "Observer" at page 377? Can it be that the boon so long sought by the gardening public—the remission of duty on tobacco for horticultural purposes, has been actually granted by the Government? It seems to me that you should at once either confirm this assertion, that "the Board of Customs has remitted the duty on ground tobacco," or repudiate it, or, at least, explain how much of this irresponsible statement is really valuable to us. If it is dependable, under what forms is untaxed tobacco allowable, and how is it to be procured? Who is Pooley? and where is his preparation to be obtained? and at what price? —P. H. G."]

FLOWERS BLOOMING DURING MAY—CAMASSIA ESCULENTA CULTURE.

I would say a word in praise of one flower during May, which is not so well known as it ought to be—viz., *Camassia esculenta*. As a pot plant in early spring it deserves a place in all cool greenhouses. It is a bulbous plant of easy culture, thriving in a compost of fibrous sandy loam and leaf mould, with thorough drainage. After flowering it should be carefully attended to until the leaves are matured; then it may be stored in the pots in any cold dry place until the autumn, when it may again be potted. It should then be placed in a cold pit where it can be kept from the frost during winter. Six or eight bulbs placed in an eight-inch pot when in bloom form a very desirable object. Treated as above and planted out in the border or spring garden in a sheltered situation, it will repay any little care that may be bestowed upon it. In appearance it is almost like one of the Ornithogalums; its flowers are of a lovely blue colour, and the plant is about 15 inches in height. A few bulbs planted together in patches, or massed, have a beautiful effect, especially in spring gardens and among herbaceous plants.—M. H., *Acklam Hall, Middlesborough-on-Tees.*

EARTHING-UP POTATOES.

I am in doubt whether to earth Potatoes or no. I find it stated in the "Garden Manual" that earthing-up diminishes the crop one-fourth; while, on the other hand, I find the universal custom in this neighbourhood is to earth them up. What is the object of earthing-up? and in cases where it is not intended to do so, is it necessary to plant deeper? If the object be to produce tubers instead of leaves I should have thought that the operation should have been performed much earlier than it is usually done.

Is liquid manure of any use to Potatoes, or is it likely to be detrimental?—Tyro.

[We never earth-up Potatoes. We plant the sets uniformly 6 inches deep, hoe frequently to keep down weeds, and draw the earth over any tubers which may have formed exceptionally near the surface. Our experiments convinced us that earthing-up diminishes the produce and retards the ripening of the tubers.

No liquid manure should be applied to Potatoes.]

GOOD CROPS OF STRAWBERRIES.

In April or May, 1865, I obtained some Strawberry plants from Mr. Rivers; I did not allow them to bear any fruit that year, but last year (1866), they bore what I consider a beautiful crop; but as I am only an amateur grower, you will correct me if my idea of a good crop falls short of what it might be. The whole of the plants were laden with berries, but it was not until the third time the fruit was gathered that I took particular notice of the quantity, when I selected a fine-looking plant, and took from it at that gathering sixty-one fine large berries; they filled a dessert-dish full. At the next, or fourth, gathering I had twenty berries, and at the fifth thirty. How many were gathered at the first and second gatherings I cannot say. The Strawberry was called President by Mr. Rivers;

the fruit is finer than that of Sir Charles Napier on the whole, and as good in flavour. The plants are very promising this year again, and on some of them I could count from four to five hundred blossoms.

I may take this opportunity of stating that La Constante Strawberry, thirty plants of which were kindly sent to me by M. De Jonghe, of Brussels, have turned out remarkably well, the fruit is fine and handsome, and, without doubt, by far the most delicious-flavoured I ever tasted.—J. H.

[Our correspondent lives in a climate and on a soil in the Isle of Wight that are most favourable for Strawberries.—Eds.]

NOTES AND GLEANINGS.

Those who are interested in the trials of the various sorts of early Peas will have an opportunity of comparing them at Chiswick during the next ten days or a fortnight, and of judging the relative merit as to earliness of the competing sorts—Dillistone's Early, Carter's First Crop, Sutton's Ringleader, and Veitch's Early. All of these bloomed on the same day, slatted on the same day, and are at present to all appearance "as like as two Peas." Dickson's First and Best is about two days later in blooming.

—— The Strawberry May Queen was gathered at Chiswick on the 3rd of June.

—— The following Floral and Horticultural Societies have announced their intention to hold exhibitions and meetings during the present month:—

June,	4th to 8th	Royal Horticultural.
„	7th to 15th	Manchester.
„	11th	Halifax.
„	„	West London Rose Show (Ealing).
„	„	Wolverhampton.
„	13th, 14th	Leeds.
„	19th	Royal Botanic of London.
„	„	Royal Jersey.
„	19th, 20th	York Grand Floral and Horticultural Fête.
„	25th	Bristol and Clifton.
„	„	Fermoy (Ireland).
„	„	Royal Oxfordshire.
„	26th	Maidstone.
„	„	Nottingham.
„	„	Wrexham.

We shall be glad to insert the dates of the Shows of any other Societies.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The late frosts have so injured and in many cases destroyed Dwarf Kidney Beans, Scarlet Runners, Lettuces, &c., that it is advisable to have recourse to any means of hastening germination, an object which is best attained by soaking the seeds. A fortnight may in general be recovered by having recourse to the steeping process. There is sometimes sufficient moisture in the ground for the first stages of germination, yet by the time that is accomplished, and before the tender radicle has extended itself beyond the reach of such vicissitudes, the drought has overtaken it, and total desiccation is the result. If the seed is on the eve of germination previous to its insertion in the soil, and if the soil is newly dug, the young plant will in general establish itself in safety. The plan which I would recommend is to steep the seeds in water at a temperature of about 80°, for about six hours or more, according to the character of the seed, and to place the vessel where it will maintain that temperature; then to strain off the water and remove the vessel to a more moderate temperature, say 65°, until the first signs of sprouting, when the ground should be instantly prepared and the seeds sown. *Broccoli*, the Cape, although a small Broccoli, is one of the most useful kinds in the kitchen garden when a constant succession is required. This is a good time to make a very full sowing to supply the table through October and November. *Cauliflowers* sown now will head in November, and may then be housed in cellars, sheds, or outhouses, and continue in use until past Christmas. It is a good plan to sow some Cape Broccoli in drills, prepared after the manner of a Celery trench; the seed to be dropped in patches about a foot apart, and the seedlings to be afterwards thinned out to about three in a patch. Sow a little more of Knight's Protecting, and a sprinkling of some very late spring Broccoli; it may serve to prolong the succession next April and May. *Celery*, every attention should be paid to the plants; they must have abundance of water in every stage. Those pricked out from the seed-bed should have well-prepared beds, the surface of which, for 2 inches deep, should consist of well-rotted manure, soaked with water, and rolled and pressed level previous to pricking out the plants. If the weather prove sunny they should be shaded with boughs.

FRUIT GARDEN.

Proceed with thinning out the superabundant shoots of wall trees, and nail those which it is necessary to lay in. By frequently going over these trees confusion is prevented, and on the whole a saving of time will be the result. The fruit must be well thinned, otherwise it cannot be fine—this applies to the fruit of Pear trees, as well as to stone fruit—taking care to leave those that may now be seen to take the lead in swelling. The shoots of Pears should not yet be cut back, otherwise the buds that ought to remain as such to form fruit-spurs will be induced to break into shoots. They ought, however, to have as much light as possible, and, therefore, the more advanced of the foreright shoots should be stopped by merely cutting off an inch or two from their points. It is now a good time to scrub the stems of fruit trees infested with scale, for the young insects are issuing from their fastnesses, and are as naked and tender as mites. Apple and Pear trees are about this time subject to the ravages of the caterpillars of the lackey moth (Clisiocampa Neustria). They are easily destroyed whilst they remain in groups, and this they do till after their third moulting, they then dissolve partnership, their united efforts in the formation of a web being no longer necessary, and dispersing over the tree in all directions their capture becomes almost impossible. Vines on walls or buildings must be attended to, as to disbudding, stopping, &c.

FLOWER GARDEN.

The Banksian Rose under glass is now going out of bloom, and should be pruned at once quite close to the old wood, in order to ensure a good bloom next year, carefully leaving all the strong young wood of this year that is well placed. Plants out of doors must not, however, be cut until the blossoms make their appearance, when all weak wood should be removed. Early-planted beds in the flower garden would be much improved by hoeing them slightly to loosen the surface after the heavy showers of rain, but do not rake them for a few days. Thin out annuals, and transplant choice kinds. Mow lawns regularly during this growing weather. Clip edgings, and endeavour to render the whole neat in appearance. When the soil is poor and the lawn looks badly, a thin dressing of nitrate of soda will have an astonishing effect; apply it in moist weather. Plant out in borders Salvias, Scarlet and other Pelargoniums, Fuchsias, or any of the other surplus plants after the beds are filled up, taking care not to crowd too much. Hardy American shrubs, such as Azaleas and Rhododendrons, on high-dressed lawns, should at this period have thorough waterings in very dry weather. Carnations must be strictly attended to; a top-dressing of rich compost will be found highly advantageous; take care that the ligatures are not too tight on the stems, otherwise they are apt to become distorted. Pinks will be blooming, tie some waxed threads round the buds to prevent their bursting. Pansies may be struck under hand-lights on a shady border; let the cuttings be put in as thinly as possible. Polyanthuses are extremely apt to suffer from the attacks of red spider; during dry weather shade is absolutely necessary for their successful cultivation.

GREENHOUSE AND CONSERVATORY.

Continue to clear away exhausted flowers in the conservatory in order to give place to fine specimens of Fuchsias, Pelargoniums, Calceolarias, Roses, or other gay and popular flowers. See that Fuchsias have abundant watering. All fires should now be entirely dispensed with, and a light screen of some sort kept at hand to ward off intense sunshine. Shade the blooms of Pelargoniums as they expand, and lower the temperature as far as practicable to prolong their beauty. Those desirous of obtaining new varieties with greater certainty, should protect them with canvas from bees and other insects which are likely to intermix the kinds. Much care is requisite in this respect, for even at best the hopes of the most assiduous are frustrated. Supply them generously with water, and occasionally with liquid manure.

STOVE.

Continue to shift young and growing stock, and to remove early-grown plants for autumn or winter flowering to the cool shelves of the greenhouse, in order to harden their wood and prepare them for early excitement. Much of the success in obtaining winter flowers depends upon this. Stanhopeas will now be blooming; the baskets should be well examined, or fine buds will be lost through contact with the sides. Let the

house have a thorough circulation of fresh air early in the morning, and if the atmosphere is warm give air most abundantly. If the fire is put out betimes the air may be somewhat reduced by eleven o'clock. Some of the free-growing kinds will be benefited by increased pot room, and those on blocks of wood and in wire baskets may have a little additional moss applied over the roots. When vigorous growth is going on never allow the young and succulent roots to perish for want of moisture, which at this season they are apt to do. Gradually expose plants coming into flower to a colder temperature if you desire to enjoy them for any length of time.

FORCING-PIT.

This pit may be profitably filled with numerous ornamental plants requiring the aid of additional warmth to bring them kindly into bloom. Among these may be classed Balsams, Cockscombs, Hydrangeas, Gardenias, &c. The propagation of Pelargoniums may also be carried on at the same time in this pit, as well as that of many kinds of softwooded plants.

PITS AND FRAMES.

Shift specimen plants as often as they require it, shade a little during the middle of the day if the sun is hot, and attend carefully to watering, giving manure water to such plants as have filled the pots with roots, but not too frequently. Do not use it too strong, and let it be as clear as possible; many plants are destroyed by a too-frequent application of manure water. Let the young stock be brought forward in small pots forthwith. Achimenes, for late flowering, may be brought on in a cold pit. Of the young stock of New Holland plants, and Heaths, Epacrises, and Cytisus, many will do best here, the pots being plunged in sand or coal ashes to keep them cool and damp.

RESERVE GARDEN.

Double Wallflowers, Mule Pinks, and some common Dianthuses, Alyssums, Phloxes, Iberises, and many kinds of dwarf Cistuses and Helianthemums may be propagated under handglasses in a shaded situation, and will be found very useful next spring.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

NEVER was there better weather for keeping the Dutch hoe going wherever it could find access, so as to knock up all weeds before they were an inch in height, and to keep a loose surface with the view of preventing heat and dryness from penetrating, and in stiff soils preventing cracking. A press of other work alone prevented us from so treating every piece of ground where the hoe could be used. For such purposes the draw-hoe is altogether out of date, and one drawback to its use is that you tread on the ground after hoeing, and to this may be added that the ground is left more in ridges, whilst the Dutch hoe, well managed, leaves a level surface and little or no trace of its working. Where weeds are only peeping through the ground the Dutch hoe goes over much more ground in the same time.

The work has chiefly been of a routine character. Being a little short of common vegetables, we have used what have been considered a great delicacy, and what in most cases find their way to the rubbish-heap—Sea-kale flower-heads, even at the risk of scarcely having enough of heads to produce seed, but which in general is easily obtained from the seed merchants. These flowering heads make an agreeable change at the hall table, or, indeed, any table with Spinach, Cabbages, or Sprouts. We consider they are best just when the bloom begins to open, and we advise those to try them who have never done so, boiling them like other Greens, with just a little carbonate of soda in the water.

Turnips.—This has been a bad season for Turnips. Whatever preventive one might adopt, the fly would be almost certain to do much damage. The farmers will mostly have the advantage this year, against their will, owing to the weather and the recent rains, especially in stiff land, of sowing late, which, owing to the greater heat in the soil, will cause the Turnips to come more quickly and stronger, and so far present a better opposition to the fly; at any rate late crops are little meddled with in comparison with early ones. Our first-sown crops in the open air are a little irregular, and this failure in the early part of the season first led us to transplant the early Turnips when the rough leaves were well formed. From our earliest Turnips, sown under the protection of glass, we thinned out as many as planted regularly a piece of a sloping bank, and hardly one has failed; they will come in before the first sowings out of doors, and with the exception of twice sprinkling with water gave no trouble, as they were too strong for the fly to nibble at. We have two patches under handlights which we will transplant if the weather should be dull, though we perceive that the last sowing, fully exposed, is as yet untouched. Of course we dust with almost everything in the way of ashes, soot, and lime to keep off the fly, but we never met with anything so effectual as Spruce branches. For many years we never were troubled with the fly, for then we used to have a lot of old fence hurdles, through which we drew branches of Spruce in winter, and most of the needle-like foliage had fallen before we wanted them for seeds. On sowing Turnips, the hurdles were placed on the ground. When the seedlings were up the hurdles were raised on six-inch pots, and ere long on larger ones, and were removed as the plants became strong. Whether owing to the scent of the Spruce, or something else, the fact remains that under such treatment the Turnips were scarcely ever touched by the fly, a fact that may be of importance to the possessors of small gardens, who thus might easily protect a small piece of Turnips. We have of late been unable to lay our hands on Spruce branches, and therefore for regular early crops we have partly resorted to transplanting. For field culture, nothing is so good a preventive of the fly as fine tillage and a forcing manure, which help to make a strong plant quickly. Even then, however, frequent sowings at times will be necessary. Notwithstanding all attempts at dusting, rolling to crush and to destroy the fly, other enemies sometimes appear. One of the best farmers of the day lately told us that on high-priced land he had a large field of Turnips that came up beautifully, but which would have soon been a desert from an invasion of black snails. He turned out all his own ducks, and all the young ducks he could beg or buy in the neighbourhood, shut them up when full, and turned them out again when hungry to help him whilst they helped themselves; and he thus saved his Turnips. A few young ducks are very useful in a garden.

Cabbage Tribe.—Our seed-beds have suffered much, the young plants dwindling away less from fly than the heavy rains, hail, and frosts, and, therefore, we shall sow over again, and that no time may be lost, we will use a mat, a cloth, or even a sash for covering them, until fairly up. It is well to make sure, even by a late sowing, and then though, as in our own case, we hope there will be pretty well enough left, still it is best at the expense of a few seeds to be sure.

Scotch Cabbaging Kale.—Of all last season's planting this is now almost the only thing from which gatherings can be obtained, and that only from a free cutting-down of the flower-stems as they appeared. The young shoots that come from the base are very tender and sweet, and will still do to make a change for a week or two. Of most of the new Greens and Brussels Sprouts we cannot say they are more useful than the older kinds.

Sowed successions of Peas, digging the ground well and enriching it moderately. After this sowing future sowings will be more for the sake of having Peas late than for the profitable returns they will render. What is sown after the day begins to shorten does not do so well as that which has the lengthening day to help it.

FRUIT DEPARTMENT.

Much the same as last week: thinning, tying, regulating, pinching, and above all watering. The Peas in the orchard-houses almost hid the stems and leaves with the profusion of pods.

A correspondent writes to say he is surprised that we did not mention cocoa-nut refuse as one of the best substances to lay along rows of *Strawberries* to keep the fruit clean. We have no doubt whatever that it is excellent; but, cheap as it is, where severe economy is practised it could hardly be recommended for use in a wholesale way, either for this purpose or the covering of flower-beds as a mulching when the ground had been rendered hot enough by the rays of the sun, though for small neat places it would do admirably for both purposes, and if carefully taken off might be repeatedly used season after season before it became decomposed. The refuse from flax mills also answers well for such a purpose. Another correspondent is surprised we did not allude to tiles and slates placed between the rows, were it for nothing but their forwarding properties in fully-exposed places. In thanking both correspondents, we would just remind them that the most easily obtainable materials, so as to be most generally useful, must form a main point in these cursory observations. For our own part we have found tiles and slates placed between the rows

forward the crop in sunny weather about a week; in dull weather they would not forward it at all. The drawback was, that in very bright weather some of the fruit would be scorched; but this was done to such a trifling extent as would prevent us finding serious fault with any one that proposed using them. With strong vigorous rows in the garden of an amateur, who can obtain no litter, &c., we do not think that any mode could be more economical than a few small sticks connected with a ball of small cord. Sixpennyworth of cord will go over a long space.

ORNAMENTAL DEPARTMENT.

We have concentrated the chief part of our strength here. We are hurrying on late subjects or those which suffered slightly, as Perilla, Amaranthus, and Iresine, as we find that young plants of these grown to some size, and planted out after the ground is warm, always do best. We have planted Amaranthus melancholicus in the end of May, and it dwindled every day, and from the same sowings we have planted-out small plants in the middle and the third week of June, that became better and better until the frosts of autumn came. We mean to try the Coleus, especially the brown one, again, but to plant a fortnight or three weeks hence, when the ground has become warmer. The worst of using such plants in a composition group is, that the arrangement is not complete at once, but we had better submit to this than turn out tender plants too early.

Amid the press of matters needing attention, we must just for the sake of the less experienced select a few, little in themselves, but of importance in securing ultimate success—much more important than turning the plants out so early as to astonish your quieter neighbours, and most likely in such a season as this has been to astonish yourself, by having much of your work to do over again. As a fact, we may also mention, that we have seen good plants turned out into beds in the end of April, and plants no better turned out in the end of May and the beginning of June, but from the end of July and onwards the late-planted ones had all the running as they liked to take it. As more important, then, than early planting, we would say—

1st, Be particular that the ground should be well pulverised, aired, and several times slightly turned over, especially after a hot day—in fact, act as if success depended in digging down sunbeams.

2nd, Be particular that all plants in pots or otherwise should be well watered before transplanting—that is, as many hours before as will permit of all excess passing away, so that, especially if pricked out in a bed previously, the weight of the soil will not cause it to fall from the irregular ball. Plants with a ball of any kind, if planted with the ball in a dry state, will scarcely be made wet by any amount of watering afterwards. In extreme cases of dry balls, it may be necessary to soak the ball in a pail before planting. As respects very tender plants, use water heated to 75° or 80°.

3rd, In planting, press the earth to the sides of the ball gently, do not press the ball much downwards, whether there be earth above it or not. Many practical men are in the habit of doing this, and thus crack and break the ball, and strain or destroy the roots, though to keep both entire much consideration had been given.

4th, In planting from pots, if the ball is at all matted with roots, gently disentangle the outside roots, by drawing the points of the fingers along the ball, and then firm the soil at the sides as stated above.

5th, In watering, use only as much as will settle the earth moistened about the roots, and not deluge the surrounding ground. In dry, sunny weather, give this watering before the earth is all replaced, so that you may put dry soil over the moist soil close to the roots. Bear in mind, that evaporation of moisture from any body cools the substance from which the vapour comes, and the damper the soil and the warmer the weather, the greater the evaporation.

6th, Keep the same principle in view in future waterings. Give the plants no more than they will do with without flagging. In bright days, if the leaves look distressed, whilst the roots are moist enough, shade, or syringe overhead, instead of deluging the roots. As to the time for future watering, for six weeks hence it will be best to water in the early part of the day, so as to have the surface soil partly dried before night. When the nights are warmer it is best to water towards evening, and then the plant, uninfluenced by rapid perspiration in the sun's rays, will have more time to absorb the moisture. Remember that the less water tender bedding plants have when first turned out, the less will the soil be cooled at night.

7th, Let all plants, especially in exposed places, be secured. For this purpose we know nothing better than small branching twigs, such as the points of Pea sticks. Spruce branches that have lain a twelvemonth in a heap, with a weight over them, as a haystack or cornstack, are the very best for such a purpose; they are full of little twigs, and if taken care of they will last a number of years. When plants grow intertwined among such twigs these become all covered, and the strongest winds will scarcely be able to throw them into unseemly wreaths or heaps. In low protected places, such trouble may be avoided, but we dare not trust a single Calceolaria, or Scarlet Pelargonium without such securing twigs.—R. F.

COVENT GARDEN MARKET.—June 5.

Supply continues fully equal to the demand; but prices are but little affected. New Potatoes bring from 3*d*. to 4*d*. per lb.

TO CORRESPONDENTS.

Books (*A Young Gardener*).—You can have "The Cottage Gardeners' Dictionary," free by post from this office if you enclose sixty-eight postage stamps, with your address. (*W. M. P.*).—Johnson's "The British Ferns." It can be had free by post from this office if you enclose forty-six postage stamps with your address. (*C. F. I.*).—We have a book full of plans, now printing, referring to the laying out of gardens which will appear in a month or two.

American Scuffling Hoe (*K. M. H.*).—We know of no one who makes it in this country. Any whitesmith could make one from the drawing.

Insect on Vine Stems (*J. D. D.*).—It is the Vine Scale, Coccus vitis. Scrape off the bark, and paint the stems with a creamy mixture compounded of soft soap ½ lb., flowers of sulphur 1 lb., black pepper in powder ¼ lb., and water 3 gallons. Boil them together twenty minutes.

Seaweed Manure—Pruning-time (*A Novice, North of Ireland*).—Seaweed is an excellent manure both for Sea-kale and Asparagus. It may be put on now, or at any time, whilst fresh, and be forked into the soil when the beds are dressed in autumn. Apples, Pears, and Plums are pruned in autumn when the leaves have fallen; but if summer-removing and pinching of shoots have been duly pursued, little remains for the knife to do in autumn.

Cost of Erecting a Vinery (*Amateur*).—It is quite impossible for us to state the cost. Apply to builders who advertise in our columns, and to others in your neighbourhood, and then make your selection from the estimates.

Kitchen Refuse (*Tulse Hill*).—The earth is the best and cheapest of deodorisers. Put the refuse on any vacant ground, and spread a little earth over it.

Ants (*H. K.*).—They may be driven away by sprinkling a little guano over their haunts daily, until they cease to appear.

Direction (*Ivo*).—Mr. Dobson, Woodlands Nursery, Isleworth.

Bean (*C. Marsden*).—We are quite sure that it is not a horse bean; but the best authorities at the Royal Horticultural Society could not help us to identify it without seeing a pod.

Grapes (*Z. Z. Z., Surrey*).—Write to Messrs. Webber & Co., Fruiterers, Covent Garden, and state what you wish.

Currants Blooming but Fruitless (*G. H. L.*).—We can assign no reason under your treatment for the Raby Castle Currant having fruitless flower-stalks, except the rich manuring. Prune in summer as before, but avoid the yearly rich top-dressing for a year or two.

Vine Unhealthy (*Blue*).—The wasted tendril-like branches are the result of the want of correlative action between branches and roots, partly the consequence of the roots being over-deep, of unripened wood, or of overcropping in the previous year. It may also, to some extent, be owing to the state of the foliage, which is completely overran with thrips. The Vines could do no good whilst in that state. Now, we can only recommend you to smoke your house four or five times with tobacco, leaving a night or two between each time. Before smoking shut up the house by three o'clock. Let all the Vines be dry, and then next morning early syringe freely with water at 100°. If the leaves are a fair sample you will have to repeat the process four or five times at least.

Preventing Grapes Shanking (*J. A.*).—For Vines planted thirty-five years we would recommend you to bring forward strong young Vines, and replace the old ones by degrees. Meanwhile, as the Vines now show so well and are so healthy, we would, to avoid shanking, run a deep drain in front of the border, and if the weather be dry water the border with manure water. If you could not make the drain you might make two or three dumb wells.

Air Roots of Vines (*E. S.*).—The roots on the stems will always be produced freely under two circumstances—first, when the atmosphere of the house is kept very moist, and secondly, when from various causes the temperature at the roots is much lower than the temperature of the house, or there is any other cause for the roots not rooting kindly at the time in the border. Some gardeners encourage them rather than otherwise; but though so long as vigorous they add to the strength of the Vine, they dry up at the colouring period when most strength is wanted. Another circumstance against them is, that whilst they root freely in the house, there is so far a check given to the free rooting in the border, and therefore we consider it advisable to cut them off rather than encourage them. As corroborative of these remarks, we may remark that this rooting inside takes place chiefly in forced vineries, where there is likely to be more difference between the top and the root temperature.

Cucumbers Failed (*W. M.*).—We could discover no insects on the Cucumber leaf, but there were marks as if thrips had been visiting you. It is a small insect, and jumps as you approach it. There are a few places that look as if visited by red spider. Neither insect likes the fumes of sulphur, such as given off by a hot-water pipe, or by the sun shining on it when plastered against a wall. Neither likes the free use of the syringe. For the thrips you will have to smoke with tobacco several times, and syringe freely; but if the generality of the leaves are as bad as those sent, we would advise bringing on young plants in another place. Take what you can from the present plants, then turn them out, removing all the soil, ants, and all, smoking the place with burning sulphur, keeping shut up for twenty-four hours. Then wash all the walls, fill them with fresh soil, and replant with the fresh plants. If the leaves are all as bad as the one sent, tobacco smoking would be more waste; if only a few are so, then smoke and syringe.

Watering Vines in an Inside Border (*An Amateur*).—Much will depend on the state of the weather. If the weather is very bright with dry wind the Vines will require water every day, especially if the border has been made of light loam that does not retain moisture long after watering, and the Vines are in a very vigorous state of growth. This applies to the period of the Vine setting its fruit, and so on to the commencement of the colouring of the berries, when they should not be so liberally supplied with water. With regard to the quantity of water to be given, "Amateur's" judgment should be his best guide. No one could state the exact quantity, as so much depends on the nature of the soil the border is composed of. If it is an open sandy soil a large quantity should be given at each watering; on the other hand, if it is a retentive soil the Vines are growing in, a less quantity will be sufficient, but small dribblets of water are not to be recommended at any time. Mr. Wills always applies it in sufficient quantity to thoroughly soak the soil the Vine or other plants are growing in. If the drainage of your Vine border has been properly seen to you cannot err by applying water in large quantities as soon as the roots of the Vine are in full action, and from that time to the period named above. As soon as all the berries have changed colour the water-pot may be put aside, only using it occasionally to keep the Vines from flagging. All the air that can be given with a higher temperature is also then required to give the berries that fine finish and flavour which are the most necessary and essential points the Vine cultivator should keep in view.

Rose Isabella Gray not Flowering (*A Ten-years Subscriber*).—We can only account for the Rose showing buds and not expanding them, from the atmosphere being kept too close and moist. Give more air, and keep the plant near the glass.

Propagating Daphne cneorum (*Idem*).—It is best propagated by layering into small pots placed in the ground around the plants. Any dispossable bushy shoots put in the soil up to the leaves, and pegged securely in the soil, and about an inch below the surface, will succeed. It is not necessary to make a slit or cut, but that facilitates the rooting. Shoots layered now will be well rooted by the autumn.

Propagation of Shrubs and Trees (*J. B. W.*).—Rhododendrons may be layered in spring before they begin to grow, or in autumn after the growth is perfected, and we think autumn preferable. Evergreen shrubs should be layered in September or in March, but the former is more desirable. Deciduous trees and shrubs should be layered in autumn after the leaves fall, and cuttings of evergreens, as Laurels, should be put in during September, or of Aucubas early in the month, and cuttings of Coniferæ at the end of August. We consider the cut in layering preferable to the twist.

Fern Fronds Blackened—Eaten by Woodlice (*Pteris*)—The young fronds die off before they unfold, from cold, wet, and sudden changes of temperature. Keep the atmosphere more humid, and avoid wetting the fronds, and give a slight increase of temperature. We never heard of woodlice being destroyed by "carbonic acid gas," and if you create such a gas in your fernery as to drive away the woodlice, we think your own life and that of those entering it will be jeopardised, to say nothing of the destruction of the plants. You say you have followed our advice and catch them by hundreds, but you really do not see that it lessens the quantity. We can only say, Set more traps or baits. We are certain you will exterminate them.

Pruning Evergreen Trees and Shrubs (*A Subscriber*).—Arbutus you may cut in in spring, but unless it grows unshapely it should not be pruned at all, and it as well as Evergreen Oaks should not have any pruning beyond the cutting out of a long naked branch, or the shortening of irregular growths. This should be done in spring before they begin to grow. Portugal Laurels should be pruned early in May, cutting them in to any shape or form required, and if compact close heads are wanted they should be gone over again at the end of August. Laurels may be cut in June, or if they require much cutting it should be done early in April. We, however, cut ours at the end of May or early in June, and again in August. Aucubas should be cut in spring before the growth is made, and then only; and the Laurustinus should be cut early in May, and the young growths not afterwards shortened, as they flower from the ends.

Solanum capsicastrum Treatment (*H. G. B.*).—The plant of which you sent us a fruit and sprig is Solanum capsicastrum, a greenhouse or half-hardy shrub. It may be placed out of doors from now until October, but is best kept in a cold frame, or cool airy greenhouse.

Genista or Coronilla after Flowering (*Idem*).—If the plant requires repotting it should be done at once. A compost of sandy loam and one-third leaf mould, with a free admixture of sand, will grow it well, and it may be cut in if necessary; but this should be done previously to potting, the latter taking place when the new shoots are a few inches long. The plant may be placed out-doors in summer, it being kept well supplied with water.

Propagating Arabis variegata (*C. F. I.*).—This plant may now have the side runners slipped off, and, being placed in sand in a shady border, and kept moist, they soon root. This may be done from now up to September; but we prefer dividing the plants now, and the divisions form nice plants for autumn planting.

Propagating Cerastium tomentosum (*Idem*).—The best method that we have tried is to put in cuttings of the last year's growth at the end of March or early in April, two or three together where wanted, inserting them so that they may be two-thirds covered by the soil. They should be put in in little tufts, or two or three branches together, about 6 inches apart from plant to plant, or from tuft to tuft. They make a splendid edging by July. Cuttings strike freely if inserted in sand and placed in a cold frame or shady border, and more quickly if placed in a mild hotbed. The plant is easy of propagation by division.

Roses for Training to House (*Idem*).—There are no evergreen Roses such as you require, but we think the following would please you, though they lose their leaves in winter, as every good Rose does:—*Bourbon*, Acidalie and Sir Joseph Paxton; *Tea-scented*, Climbing Devoniensis, Gloire de Dijon, and Maréchal Niel; and *Hybrid Perpetual*, Maréchal Vaillant, Madame Louise Carique, Madame de Cambacères, Lord Raglan, Jules Margottin, Madame Julie Daran, and Eugène Appert.

Insects in Cucumber Frame (*Constant Reader, I. M.*).—We think from your description that the insects of which you complain are woodlice. They cannot be thrips, as these confine their excursions to the leaves and stems, and may be found on the under side of the leaves of plants attacked by them; besides, tobacco smoke will destroy them, which you say it does not those ravaging your plants. Procure a toad or two and place in the frame. They will clear the bed of woodlice in a short time. We keep them in constantly.

Ferns (*K. M. H.*).—Write to Mr. Sims, Nurseryman, Foots Cray, Kent.

Preserving the Colour of Dried Flowers (*Rus.*).—Arrange and press the specimen flat; then put it into a tin dish partly filled with dry sand, cover the specimen with more dry sand, and place in an oven at a heat that will dry the plant quickly without scorching. We are told that this mode preserves the colours. We shall be obliged by information on this subject.

Names of Plants (*C. F.*).—Andromeda mariana. (*Constant Reader*).—Asplenium adiantum nigrum: 1, Tradescantia virginica; 2, Metrosideros citrina; 3, Veronica gentianoides. (*T. B.*).—1, Pellæa geraniifolia; 2, Selaginella Kranssiana (?); 3, Asplenium rhizophornm; 4, Pellæa hastata; 5, Asplenium falcatum; 6, Adiantum trapeziforme. (*H. B.*).—1, Adiantum pedatum (?); 2, Adiantum capillus-Veneris; 3, Asplenium marinum 4, Pteris chinensis.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 4th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ROYAL AGRICULTURAL SOCIETY'S POULTRY SHOW AT BURY ST. EDMUNDS.

It appears that the Committee do not intend to pay any attention to the appeal of "Nemo," either by postponing the date of entry or rescinding the rule which imposes a fine of 10*s.* per pen if the poultry is not sent.

I thought I would try them, and so sent an entry, but refused to "engage to forfeit and pay a sum of £20 if the birds should prove on entering the yard to be suffering from any infectious disease," or "to pay a fine of 10*s.*" if they were not sent, the "only exceptions to the fine allowed being death or disease." As "Nemo" says, "a thousand circumstances may occur" in that time to prevent one from sending them—"the hens may be broody," or some of them may be stolen, &c. Some thieves paid me a visit a fortnight ago, broke into my Duck-house, and cleared the place. I might have had them entered, and, to make amends for my loss, I should have had to have paid a fine of 10*s.* for losing them! Further, the exhibitor is called upon to state exactly the very pair of birds he intends to send; their exact age to a "day" must be stated separately, and lest he should not be able, or willing, to state the precise age, the Committee ask for the date of their hatching! I suppose they think poultry fanciers keep a "register of births," or that, if they happen to have a dozen cocks and hens of the same kind, they shall not be able to send any but the identical pair entered, although the others may at the time of the Show be far more eligible than those it was first intended should be sent. There is neither sense, reason, nor good policy in such regulations. Do the Committee think poultry fanciers as a class are so short-sighted as to send valuable birds from home to be penned up for a week when they know they are suffering from disease? The probability is the birds would be dead long before the end of the Show. Or do they think that after paying an entrance-fee of 5*s.* per pen every one would not try to send his fowls if at all practicable?

Well, I sent an entry, but stated I would not "engage to do anything so absurd" as to subscribe to these rules, but would agree to "forfeit the entry money if not sent, which was enough for all purposes." Mark the result. My entry money is returned to me with a note to the effect that the Committee "cannot accept my entry unless on the terms printed on the certificate." Surely such policy is suicidal, for, as "Nemo" says, "be and many others" will, no doubt, "keep their fowls at home."—J. R. J.

COMB OF THE DORKING HEN.

Your statement that "the comb of a Dorking hen should be moderate in size, well serrated, and should hang over the side," seems to me to reveal a weak point in the present system of judging, upon which I should like to have the opinion of Mr. Hewitt, or some other good authority.

Nothing is more essential in a Dorking cock than that his comb should be straight, and yet the comb of the hen "should hang over the side." You are not alone in this assertion. Mrs. Arbuthnot states that the comb "should fall over on either side." If this rule be correct, how, let me ask, are you to breed perfect birds? If I wanted cocks with perfect combs, surely I ought to obtain hens as well as cocks whose combs do not fall over, either on one side or the other? Yet you say, that "those who are skilled in, and very observant of poultry, look 'awry' on very upright combs in hens."

It seems, then, to me, that a straight comb ought to be no drawback to a Dorking hen, but rather one of her qualifications, provided it be correct in other respects. Unless, indeed, the present rule be modified, I do not see how you can expect to breed prize cocks from prize hens.—E. M. B. A.

[We forwarded the preceding to Mr. Hewitt, and this is his reply:—"In giving my opinion as to the formation of the comb of a Grey Dorking hen, I quite agree with your published statement, that the comb should be of moderate size, well-serrated, and hanging over the face on one side. The theory propounded by 'E. M. B. A.' of breeding from what is commonly known as a 'prick-combed' Grey Dorking hen, has been again and again attempted, but I never yet knew a single individual who persisted in the experiment a second year, for disappointment was the invariable issue, and the chickens thus produced proved utterly useless for exhibition. If your correspondent purposes breeding Dorkings, I would strongly advise him to adopt the very plan he repudiates at present—viz., mate together a cock having a perfectly upright comb with hens whose combs fold and then turn over the face, it matters not on which side. He will then find, if well-bred stock birds, that all his chickens will have combs exactly of the same formation as the parent birds. In Spanish fowls the same rule again holds good. It is only great age or want of health and condition that will cause the combs of either Spanish or Dorking cocks to fall over, if they are truly-bred birds. In the latter case, it very frequently happens that restored constitution causes the comb to become again as erect and firmly fixed as ever. The different formation of the comb is, in the breeds referred to, simply characteristic of sex, as is the mane of a lion or the antlers of a buck.—Edward Hewitt."]

POULTRY AT THE BERKS AND HANTS AGRICULTURAL SHOW.

We are glad to note an upward tendency in this Show. The experiment of moving from town to town is a success, and enlists new supporters at every place visited. In common with other agricultural meetings this suffered by the absence of cattle; but the show of sheep, horses, &c., was so good that the yard was filled, and no ugly gap in the rows told of the existence of the "Pest" in some parts. Hampshire is, fortunately, free from it. These shows are now so thoroughly understood, that they become training schools for farmers who are still in search of knowledge and anxious to learn. Thus, the mowing machines are no longer exhibited in a row in the implement yard, but they have their trial at actual work one against the other. No one can overestimate the importance of seeing machinery in motion, and we believe that more can be learnt by spending an hour with the machines in action, than by a great amount of study of diagrams and lectures.

The progress, however, is not confined to horses, sheep, pigs, or machinery. Our department also increases, and the notabilities of the poultry world meet for a friendly joust at Basingstoke, Reading, or Winchester, as the case may be. We have published the prize list, which will afford an earnest of the quality of the birds. Colonel Lane's *Dorkings* were of the highest merit, as were also the second-prize birds. These latter owed their position principally to the fact the hens were unequal, one very good, one very inferior. The White Dorkings were unusually large and good. There was a bird of great size in pen 15, but so decidedly yellow in his hackle and saddle that he could not be considered a white bird. The *Cochins* were *very* good, especially Miss Millward's prize pen. *Game* left nothing to desire, the Brown-breasted Reds being the best birds. This Show has a name for *Polands*. Mrs. Pettat's Golden and Mr. Edwards's Black with white tops maintained their old reputation. The *Spanish* were the best that have been ever shown at this Show. Mr. Pittis's first-prize pen of Golden-pencilled is among the best we ever saw. Though we cannot say as much for the Spangled, yet we are warranted in saying the first and second prize pens were very meritorious. There was great competition in *Brahma Pootras*, some of the best yards being represented. The prize birds were nearly even, and a pen of chickens shown by Mr. Fowler deserves notice. They were early, and we thought them birds of promise. We come now to a class that fairly demands an increase of prizes. Two are not enough for twenty pens to compete for. There were eight deserving prizes and only two to award. We have seldom seen so many good Duckwings as at this Show. The Variety class, comprising Andalusian, La Flèche, Malay, Gueldres, Silkies, Crèvo Cœur, and nondescript, was amusing as well as attractive. It may give rise to discussion some day. There was a dumpy La Flèche, all the points well developed, save that she seemed a gallinaceous "Widdrington," and stood "upon her stumps." Then we had a vulture-hocked La Flèche cock. This is the first time we have seen such a monster. We make no doubt that in 1869 there will be a party declaring that vulture hocks are the correct thing for a La Flèche cock. We hereby enter our protest. The Malays were excellent.

Then we came to *Ducks*. Aylesbury and Rouen took their places first and second. Some beautiful small Buenos Ayrean, and a cage of very tame and graceful Pintail were obliged to be content with high commendations.

Pigeons are daily becoming greater favourites. The present Show was no exception. The Carriers, Tumblers, Fantails, Trumpeters, and Magpies, noticed in the prize sheet, were all highly meritorious. In the Magpie class, one pair that took second prize was of surpassing beauty. The Various class showed Nuns, Barbs, Jacks, Swallows, and White Jacks.

Then large downy *Rabbits*, with ears dropping and trailing on the ground, called for our attention, the first-prize one measuring 19½ inches in length, and 4½ in width; the second, 18¾ in length, by 4½ in width. Foreign brought pretty Himalayans, but we doubt whether any of the rough-haired are really "Foreign." The next was a large class for

Rabbits (to include all points). Many were very good, and deserved prizes.

Captain Booth, an amateur in the neighbourhood, sent a most attractive and remarkable collection. Two large cages, placed on a carriage, were decorated with flowers and evergreens. They had perches of peeled wood, that shone in the sun, and were tenanted by a score of Golden and Silver cock Pheasants, all in full plumage. These had for companions Doves—White and Barbary. Another cage held a Chamois, and another a Bartavelle. All seemed perfectly happy and fearless, and it was apparent to all it was not "their first appearance on the stage."

The band of the 60th Rifles, the trials of hunters over six hurdles, a charming "locale," and an excellent and numerous attendance, combined to make this a rural Fête, as well as a successful Show. A working Committee of gentlemen, and the zealous and experienced services of the Secretary, Mr. Downes, deserved no other result.

Dorkings (Coloured).—First, Lieut.-Col. Lane, Bracknell. Second, C. Cook, Shoreham, Sussex. Highly Commended, Mrs. St. John; Lieut.-Col. Lane. Commended, H. Portsmouth, Basingstoke.

Dorkings (White).—First and Second, H. Lingwood, Barking, Needham Market, Suffolk. Commended, G. Butler, Bullsdown, Bramley.

Cochin-China.—First, Miss J. Millward, Newton St. Loe, Bristol. Second, Rev. S. C. Stamerton, The North Gate, Warwick. Highly Commended, Rev. W. C. H Hughes D'Aeth, Arborfield, Reading. Commended, S. D. Forbes, Portsea; Mrs. St. John.

Game.—First, S. Dupe, Everereech, Bath. Second, S. Matthew, Stowmarket. Highly Commended, J. Seken, Eltham, Kent; J. Mason, Worcester.

Polands.—First, Mrs. Pettat, Ashe Rectory. Second, T. P. Edwards, Lyndhurst. Highly Commended, T. P. Edwards. Commended, Mrs. Pettat.

Spanish.—First, A. H. Drummond, Maidenhead Thicket. Second, J. Jenner, Lewes. Highly Commended, F. James.

Hamburghs (Silver or Golden-pencilled).—First, F. Pittis, jun., Newport, Isle of Wight. Second, H. Pickles, jun., Earby, Skipton.

Hamburghs (Silver or Golden-spangled).—First, Mrs. Pettat. Second, T. Walker, jun., Denton, Manchester. Highly Commended, Mrs. Pettat.

Brahma Pootras (Light).—First, R. Dowsett, Pleshey, Chelmsford. Second and Commended, J. Pares, Postford House.

Brahma Pootra (Dark).—First, J. K. Fowler, Aylesbury. Second, F. James, Peckham. Highly Commended, Lieut.-Col. Lane; J. K. Fowler.

Bantams.—First, F. Pittis, jun. Second, Mrs. Pettat. Highly Commended, W. Boutcher, Notting Hill, London; Rev. J. De L. Simmonds; E. Sheerman, Chelmsford; Miss R. Read, Nutley, Micheldever; F. Pittis, jun.

Any Variety not Before Mentioned.—First, J. K. Fowler (Crève Cœur). Second, J. Hinton, Hinton, Bath (Malays). Third, W. Weston, Bramley, Guildford (Andalusians). Highly Commended Mrs. St. John (Silkies); S. C. Phair, Southsea (Crève Cœur.)

Ducks.—First and Second, J. K. Fowler. Highly Commended, T. C. Harrison, Hull; Miss J. Millward.

PIGEONS.

Carriers.—Prize, H. Yardley, Birmingham.

Tumblers.—First, J. Ford, Monkwell Street, London. Second, — Martin, Hulme Barracks, Manchester. Highly Commended, J. Ford; H. Yardley; — Martin.

Fantails.—First, Miss J. Millward. Second and Highly Commended, H. Yardley.

Trumpeters.—First, H. Yardley. Second, A. P. Maurice, Herriard Grange.

Magpies.—First, — Martin. Second, F. Pittis, jun.

Any Variety not Before Mentioned.—First, H. Cawood, Thorne, Doncaster. Second, H. Yardley. Highly Commended, H. Yardley; Master W. Barton, Basingstoke; H. Cawood; G. Hill, Winchester.

Rabbits.—*Longest Ears.*—First and Second, G. Hill. *Foreign.*—First, H. Cawood. Second, Mrs. M. Churcher, Stratton, Micheldever. *Variety to include all points.*—First, G. Hill. Second, F. Blunden, jun., Basingstoke. Highly Commended, J. Ruff, Basingstoke; J. Astlett, Polhampton, Overton; P. Warren, Southampton; H. M. Maynard, Holmewood, Ryde; H. Child, Birmingham; F. Blunden, jun.

Judge.—Mr. John Baily, 113, Mount Street, Grosvenor Square, London.

LAUNCESTON POULTRY SHOW.

This was held on the 29th of May, in connection with the Show of the Royal Cornwall Agricultural Association. There were 160 entries, and in all classes there were good specimens of the several breeds. The prize list is as follows:—

Dorkings (Coloured).—First and Second, Rev. A. C. Thynne, Poustow, Stratton. Third, R. W. Beachy, Kingskerswell Commended. T. Smalo.

Dorking.—*Cock.*—Second, F. Phillips, Calstock.

Dorkings (White).—First, Lieut.-Col. Archer, Trelaske. Second, Mrs. Wollecombe, Stowford Rectory.

Spanish.—First, J. H. Reed, Clastock (Black). Second and Third, G. T. Sleeman, Pyworthy. Commended, J. H. Nicholls, Lostwithiel (Black.)

Cochin-China.—First, F. Phillips, Calstock (Buff). Second, Mrs. Wollecombe (Buff). Third, T. E. Hawken, Lostwithiel (White.)

Game.—First, J. Francis, Kilkhampton. Second, T. Pickard, Stratton (Black-breasted Red). Third, A. West, Bude (Black-breasted).

Game.—*Cock.*—First, A. West (Brown-breasted). Second, J. Callacott, Tavistock (Black Red). Highly Commended, J. Callacott (Brown-breasted). Commended, R. W. Beachey.

Brahmas.—First, R. D. G. Consols, Tavistock (Dark). Second, J. H. Nicholls.

Malays.—First and Second, H. Darch, Stratton.

Cornish.—First and Second, D. Maynard, Stratton.

Hamburghs (Golden-pencilled).—First, J. F. Delmar Stratton. Second, J. H. Nicholls. Commended, N. Barter, Plymouth; J. F. Delmar.

Hamburghs (Silver-pencilled).—Prize, N. Barter.

Hamburghs (Golden-spangled).—First, J. F. Delmar. Second, J. Medway, Menheniot.

Hamburghs (Silver-spangled).—First, S. Blanchard, Tavistock. Second, W. M. Lancaster, Thuborough, Holsworthy.

Polands (Golden-spangled).—First, S. Sly, Werrington. Second, T. E. Hawken, Lostwithiel. Third, T. Chudley, Plymouth.

Bantoon.—First, J. B. Lyle, Launcells. Second and Third, J. S. Perry, Whiterow. Fourth, W. J. Lyle. Fifth, J. H. Nicholls.

Bantams (Black and other colours).—First, H. M. Brazeley, Bideford. Second, — Morgan, Egloskerry.

Guinea Fowls.—First and Second, W. M. Lancaster.

Ducks (Aylesbury).—First, J. H. Nicholls. Second and Third, J. Binds, Bridgerule.

Ducks (Common).—First, J. Jackman. Second, J. K. Cotton, Marhamchurch. Third, D. Brent, Linkinhorne.

Ducks (Rouen).—First, W. Raddall, South Petherwin. Second, A. Jeffery, Lifton.

Pigeons.—*Common.*—First, J. Brock. Second, J. Heal, Buckland Brewer. Third, J. K. Cotton. *Carriers.*—Prize, R. Carter, Penzance. *Barbs.*—Prize, R. Carter. *Pouters.*—Prize, W. H. Scott, Exeter. *Fantails.*—Prize, R. H. Clay, Launceston. *Jacobins.*—Prize, R. Carter. *Trumpeters.*—Prize, R. Carter.

The Judges were Messrs. H. Tyrrell, J. Dunning, E. Carlyon, and H. Leeworthy.

NEW BOOK.

The Practical Poultry-Keeper. By L. Wright. Cassell, Petter, and Galpin. 1867.

Another book on Poultry! Surely the fancy is increasing rapidly, for many new works must show the advance of the subject in popular esteem. Another new work, and another good one too, and one containing a considerable amount of original matter.

I own to being somewhat influenced by the size and appearance of books. The booksellers manage these affairs, and they're cunning men, manage them well. Somebody said that the west end of every town was its best part; it was a theory which did not bear the test of proof, but my book theory will. For instance: there is the large, broad-margined, ornamentally bound book with beautiful pictures; well, that is meant for a drawing-room table ornament, and the pictures are the best part of it. Then, of course, we all know what three purple-clad volumes contain, and how they are not read, but skipped and rattled through by young ladies (Would they had something better to do!), and how they are secreted by school girls from the severe-eyed spinster who rules them—for their good. Then there are the two volumes, rather large, of travels; the one thick volume for the gentleman's business-room; and the neat-looking book, handy to hold, and which opens nicely, and is of good type. This volume is meant to be read and referred to, it lies open so easily, and is therefore full of practical matter.

Now just such a volume is Mr. Wright's. It is divided into sections, which sections I will review in their order. The first is headed, "The Management of Domestic Poultry, with a View to Profit." In this section and the one that follows, on "The Breeding and Exhibition of Prize Poultry," lie the strength of the book. They are evidently written from personal experience, and there has been also a quick eye and a handy pen at work. Mr. Wright starts with the idea that his reader may be "totally ignorant of poultry-keeping," but that he wishes to learn and prosper. Perhaps some may object to the somewhat positive and commanding way in which Mr. Wright gives his instructions. Thus he says, "The pages of this [the first] section are not intended simply to be read and commended," but the orders are "meant to be done;" and "such food must be regularly given." Well, nothing of this sort can be too plainly put or too strongly expressed, in order that it may be implicitly followed. What Sir Charles Napier said he felt to want at Meanee, and what he wished the great Duke would write, was a few positively written plain orders, which a general could not forget: so poultry-keepers want a few positive, plain, good rules, so put as to be always remembered. Our author writes as an old uncle speaks to a young nephew—"Now mind, young man, you must do this, and you must not do that," &c. If by thus writing Mr. Wright makes us feel young again—well, that is not objectionable.

Mr. Wright insists on personal attendance, and bringing up the children of a family to look after fowls; and the consequence will be that very soon they will grow to love their charges. He lays, also, strong emphasis upon the grand rule of cleanliness in the fowl-house, and that it must be "perfectly waterproof, yet well ventilated, and yet no draught, and that sunlight must reach the birds some time during the day." His plans of poultry-houses are good. In choosing fowls he gives a good description to guide the beginner as to knowing a young bird, and also the absolute need of having young birds

every year if winter eggs are desired. In his hints on feeding I coincide with him in his recommendation to give the last meal in the day of whole corn. Indeed, all Mr. Wright's practical remarks are worth notice. Thus, the water-vessel he recommends, having an opening at the top closed by a cork, is much preferable for cleansing to the ordinary stone fountain. The chapter on Incubation is full of good hints. The advice about moisture is perfectly correct. I would advise that if you must sit a hen in a box on wood, as in a hayloft, cut a large turf, and set the box on it, and wet the turf now and then. Rearing, Fattening, and Diseases are noticed in their turn.

Passing on to Section II. we come to Mr. Wright's advice concerning "The Breeding and Exhibition of Prize Poultry." Profit and fancy are usually two separate things, yet fancy poultry may frequently pay well. Be it so, yet I wish the English lower middle class could make ordinary poultry so profitable, that the money spent on foreign eggs could go into English pockets. The chapter "On Scientific Principles of Breeding, and the Effects of Crossing," may not convince all minds, but it is well written, and very interesting. One remark is undoubtedly true, "without foundation by long-continued selection no strain can be depended on." This I have found to be true over and over again. The remarks on "Treatment of Fowls Before and After Exhibition," should be tested by the reader's own present and future experiences.

The third Section on "Different Breeds of Fowls," is less new, as upon its subject so much has been of late written. All except Brahma fanciers will, I fear, think the chapter on that breed too long in proportion to the space given to other varieties; but, without doubt, those who have contributed descriptions of the breed understand it thoroughly. I may instance Mr. Pares, Mr. Hinton, and others. This latter remark applies to, other contributors to this section. The chapter on Game fowls is written by "Newmarket," who gives his name, and of whom I may, therefore, speak as Mr. Trevor Dickens. I wish this gentleman would publish a separate book on Game fowls. He understands this breed thoroughly, and combines the now rare knowledge of the bird in its former pugnacious character, and its present character as a bird for the show pen. I ask, too, because even in a recent and large work the chapter on Game fowls is very meagre. Such a book well illustrated would be valuable, for it would record permanently facts already dying out, because the pastime is gone; and certainly Mr. Dickens knows thoroughly the Game fowl in all its varieties, and would not pass them over as of mere local knowledge. After the English breeds, the French varieties are mentioned at large. I imagine the Houdan will in time be extensively bred in England. Then the Bantams are briefly noticed—too briefly; and lest any fowl should be offended, the very barndoor bird is written about. Looking at him in this pretty book, I say—

> "This bird we know is neither rich nor rare,
> The only wonder is, how ever he got there."

Section IV. treats of "Turkeys, Ornamental Poultry, and Waterfowl." Section V. of "The Hatching and Rearing of Chickens Artificially," and the sixth and last Section treats of "The Breeding and Management of Poultry upon a Large Scale," as shown in France, at Belair. The last section I read in Cassell's monthly number.

Thus I have briefly reviewed Mr. Wright's work, and pronounce it to be what its title declares. More pretentious books on poultry, and kindred subjects, are often made up chiefly of quotations from well-known works, and have no claim to originality. Not so this book. The illustrations are not equal to the letterpress, but the waterfowl are better than the land birds. None but a poultry fancier can well illustrate fancy poultry; even to a good artist a fowl is a fowl, and no more, and its points are not seen. Plainer backgrounds cause figures to stand out sharper and clearer.

In conclusion, I may state that Mr. Wright is the "Nemo" of our columns; *now* "Nemo" is somebody. — Wiltshire Rector.

INCREASE OF PRIZES FOR CANARIES AND RABBITS.

Permit me to make a few remarks on the great falling off in the entries of Rabbits and Canaries owing to the small amounts given as prizes. For instance, fanciers living at a distance are obliged to forward their stock by rail, the cost of so doing, even for a single Rabbit or Canary, being more than the value of the first prize should it be fortunately obtained.

Now, in the opinion of a large number of fanciers, and having the best intentions towards these exhibitions, the following alterations would be advantageous, and I trust Committees will take them into consideration:—Instead of giving the small prizes that are now given, and only charging small sums for entrance, we wish for £1 as the first prize, and 10*s.* as the second, and 2*s.* or some such sum to be charged for entrance fees. The entries would be largely increased.

It is well known that long-eared Rabbits are very valuable, also pure-bred Belgian Canaries; Rabbits often being sold for from £5 to £10 in these exhibitions, and Canaries often for very large amounts.—John Taylor, *Sheffield.*

BEE-KEEPING IN RUSSIA.

(*Continued from page* 304.)

A pound of drained honey costs in these countries from 1½*d.* to 3*d.* Honey in the comb is somewhat more expensive, costing 3½*d.* per lb. Honey is always filtered on a warm hearth through a sieve of bast, in order to separate it from the wax. Wax, which however is very often adulterated with tallow and pea flour, costs from 9½*d.* to 1*s.* per lb. All this, however, as far as regards prices, holds good only for the more southern governments, as, for example, Isaratoff, Irenburg, &c. In the more northern governments, especially Moscow, the prices are different, and are often more than double what is above stated. In Moscow, on the honey-feast, the 1st of August, a pound of honeycomb costs from 1*s.* to 1*s.* 4*d.* per lb.; in autumn 10*d.*, and in the months of February and March, during the great fast (Lent), from 1*s.* 6*d.* to 2*s.* During the great fast an enormous quantity of honey is consumed, as all the orthodox Russians are allowed to drink tea, which is the chief beverage, only with honey or raisins, as sugar is not "pure for fasting," because it is cleaned with burnt bones. A pound of wax costs from 2*s.* to 2*s.* 6*d.* in winter. In Petersburg the prices are the same.

He who would send *en gros* fine honeycomb in frames from Germany to Petersburg in February or March could make a very good business of it, as honeycomb in Russia is comparatively bad—*i.e.*, it is in small pieces and broken, while those who buy usually look out for larger pieces, which, however, as Dzierzon's system is not known there, it is difficult to obtain.

In the western governments the bees are treated in an entirely different way to the east. In the north-west of the Russian governments of Nowgorod, Pskow, and the formerly Polish provinces of Ismolensk and Witebsk, they leave the stocks in the open air on their stands in winter without surrounding them with straw, &c.; nay, they do not even take the trouble to close the rabbets, &c. with clay, &c. The stocks being lagers, resting at a small height from the gronnd, are often buried so far in the snow that only the higher point is to be seen; (they do not lie horizontally as has been mentioned). But, nevertheless, although they are lagers—as the head is raised they are to be considered as half-lagerstocks—and are exposed for six months to intense cold, which often reaches — 30° R. (32° below zero of Fahr.), and lasts long; most of them winter well. The snow, which almost buries them, is perhaps the cause of it; nay, in one of two stocks belonging to a neighbour of mine in the government Ismolensk, where I lived in the years 1860-1862, the lower door had fallen out in the winter of 1860-1, and the opening, more than 1 foot by 6 inches, remained open until spring without the stock dying. I tried the same experiment with my klotzbeuter in the winter 1861-62, of course on purpose. The lower opening remained the whole winter exposed to storm and snow, and on the 21st of April the bees very cheerfully flew out for the first time to clean themselves, and I counted at most from 100 to 150 dead bees. The following day they carried in pollen of Anemone pulsatilla.

In spring, as soon as the bees have held their flight for cleaning themselves, all the lower part of the comb in the stock is removed, so that only 18 inches remain.

This is considered necessary, that the bees may "work more industriously." After cutting out the combs, the stocks which are poor in honey receive a few pounds of honey, which is mostly granulated. The swarms which, in spite of the bad treatment, issue rather early here, often in the beginning of the first week in June, are all placed singly, in spite of their light weight of 2, at most 4 lbs.; the latter weight only occurs exceptionally. Only late swarms, which often weigh merely three-quarters of a pound, are united together. In the month of July honey is taken in proportion from all the old stocks, even from those that have given swarms, if only a few ounces, and 6 inches or somewhat more of the lower part of the combs, even if filled

with brood, is cut away that the bees may not "be idle." In autumn the honeycombs are cut out, and honey is given to all strong stocks which are poor in honey, according to their want. Empty combs are cut away at the top of the hive, and honeycombs are inserted instead, and they try by means of wooden pegs to give them a regular position.

Stocks which are too weak are destroyed, but the bees are not killed, nor united with other stocks, but they let them disperse where they like. In all these countries little honey is obtained, in spite of the luxurious vegetation. In spring the best gathering is from anemones, especially pulsatilla, different kinds of willows, poplars, maples, ashes; in summer from Rhamnus frangula, Prunus padus, Sorbus aucuparia, white thorn, and bilberry, from large areas of Thymus serpyllum, later from the very extensive buckwheat fields, and lastly, late in summer and in autumn, from the enormous quantity of heath. The pines and fir trees which alternately form large forests here, are of no use to the bees in these countries.

In the same manner as in the countries mentioned, the Esthen Letten and others in the provinces on the Baltic manage their bees, with this difference, that the klotzbeuter-ständers, which are the principal hives there, are taken into a cold chamber, &c., during winter. In the more southerly-situated western provinces of Russia and in Poland the stocks are taken for the winter into dry cellars, or under the floors of dwellings, after a few boards have been removed and a hole has been dug in the ground for this purpose.

The owners of a great many stocks dig large pits on elevated spots, place the stocks in them, and cover the pits with thin beams or refuse boards, on which is placed a thick layer of straw, and a sloping roof to shoot the water off. It is strange that the bees are wintered in the open air in a large part of the north-west, and in-doors, &c., in the milder south. In spring, when the snow is gone and great cold is no longer to be expected, the stocks are again placed in the open air, but no care is taken that every hive be put in its former place; this is nowhere in Russia attended to. The following day, after placing the stocks again in the open air, they are cleaned of dead bees, rubbish, mouldy combs, &c. All the lower part of the combs, to the first cross of the klotzbeuter, more than a foot high, is then cut away, just as we have seen in the more northern part of Russia. At the swarming season almost all the swarms which issue are placed singly, the smaller ones in smaller hives, which are often but 6 inches in diameter, but from 1¾ to 2 Prussian ells (3½ to 4 feet) long or high. Only late swarms and very weak ones are united. In autumn all the stocks, whether young or old, which have too much or too little honey for the winter, are killed with brimstone by the owner himself, and a similar mixture is obtained as in the east of Russia.

In South Russia, the desert districts, where straw cylinders are used, the bees are treated in the same way.

In Poland proper, partly the swarming system, partly the pruning method is employed, and in the same manner as with stocks with immoveable combs in Germany; the hives are kept in special bee-houses. The artificial increase of stocks, however, is as unknown in Poland as in all the other parts of the Russian empire. I was stared and laughed at in the different parts of Russia when I told the clergymen, &c., of artificial swarms, &c. That the drone is a male and the worker a neuter is quite strange to the people in all Russia. With regard to the queen, they are all clear about her in Russia proper; the queen they consider the female, and call her mother; but the workers are said to be the males. Only in many parts of Poland and the provinces on the Baltic the queen is taken for the male bee, the workers for females, and the drones for the nurses of the brood, for which they (the drones) are taken throughout the whole empire.

Boviat (fungue), is nowhere used for fumigation. Foul brood is only known in the western provinces; lately, however, it has appeared also in the government of Moscow, thus rather easterly; in the proper east, however, this disease is not known at all. Dysentery only appears but rather frequently in the west. Strange to say, this disease is unknown elsewhere, although the bees in Russia are obliged to remain inside the hive during the whole of six months.

With regard to klotzbeuters, I have still some remarks to make. They are mostly made of oak or fir trees, less frequently of lime trees, besides being worked more roughly. Inside they are hollowed out carefully (smoothly), and equally in diameter. They are distinguished from the German klotzbeuters by having a piece of wood driven in as a wedge outside, just in the middle, through the opening of the door, which piece of wood projects at both sides and forms two handles, and at the same time divides the stock outside into two equal parts, each of which receives a solid door—a thick board. In the western governments only where lager-klotzbeuters are kept they are not divided by a piece of wood. It may also be mentioned, that in all Russia proper some honey is taken from the strongest stocks at the end of July, besides the proper honey harvest in autumn, in order to be able to supply the public with honey on the 1st of August, the honey-feast, when every wealthy Russian provides himself more or less with honey.—Edward Assmuss.

A Bee City.—Mr. Carpenter, one of the great bee-masters of Hampshire, died a few days ago. He had two hundred stocks. He and his ancestors have resided at Godfrey's Farm at Beaulieu, in the New Forest, for upwards of a century.

OUR LETTER BOX.

Crève Cœur's Feathers Ragged (*C. E.*).—This is the time of year when the plumage of fowls is brittle and shabby. Feathers that are damaged and sickly now, will not be renewed till next moulting time, when, we have no doubt, your bird will regain a perfect appearance. Thousands of hens that enjoy every possible advantage are in the same plight as yours.

Killed by Over-kindness (*T. E. P.*).—Your chickens are over-stimulated; they do not require to be under glass, nor do they want so much egg as you appear to give. Move them out on to grass, doing so in the heat of the day, that the change may not be too great or sudden; keep the hen under the rip, but let the chickens run about. They will then do well. They are dying from being over-stimulated, and you may discontinue the egg altogether.

Dudding Scissors (*W. R.*).—We find no difficulty in obtaining them at any good cutler's. Those used by grooms for clipping horses answer the purpose very well.

Incubator Regulator (*K.*).—We never heard of a regulator which could be affixed to the ordinary gas burner of an incubator; such, for instance, as a mercury float that would, in rising and falling according to the temperature, turn on and diminish the gas.

Rice for Fowls (*Clara*).—Rice is the least nutritious of all the foods available for poultry. It may be given in moderate quantities, either during very hot weather, or when fowls have become too fat and it is desirable to reduce them.

Dorking Cock Paralysed (*C. G. S.*).—The loss of power in the legs, walking backwards, and staggering, are indications that a blood-vessel is ruptured on the brain. Keep the bird quite quiet and cool, and on low diet; the oozing then sometimes, but rarely, ceases, and we have known the birds afterwards recover.

Pigeons Laying Soft Eggs, &c. (*W. I. I.*).—Your Pigeon troubles have arisen from one chief cause—the birds being confined. Had they been at liberty, they would by exercise and picking up various things have kept themselves free of disease, which high feeding without air and exercise will frequently bring upon these birds, and Trumpeters are not very active, but will sit in the same place for hours. Our Pigeons walk about the garden, and at some periods of the year feast on green seeds, as their deeply dyed beaks plainly show. We would advise you to sow a large shallow box or pan with lettuce, cress, and cabbage seeds, and when nicely grown put the box in your loft. Pigeons like to pluck at green food when growing, but do not care for it when cut, apparently being better able to nip off a piece when the plant stands firm and fixed. Also feed low, avoiding tares and beans, and let your birds have a bath daily, and salt in the house. Mashed potatoes would also be beneficial, likewise a dose of castor oil. Inflammation from high feeding and confinement being the disease, the cure must rest in any means which will lower the system, and remove the fever.

Pheasants—Duration of Sitting—Feeding (*W. S. H.*).—Pheasants sit twenty-two days, but sometimes a day or two longer. You can keep cock Pheasants of every sort together, provided there be no hens—you cannot keep them together in pairs. The young require to be fed on eggs boiled hard, and chopped fine, on curd made of milk and pressed dry, bruised wheat, rice boiled in milk, dough made of oatmeal, and if they are sick, on ants' eggs.

Feeding Cygnets (*W. I. I.*).—Let the cygnets and the old Swan be shut up for three or four days. They should have a shallow vessel, with growing grass at bottom, some lettuce cut in long narrow strips, and oatmeal enough to cover the surface of the water. After they are at liberty, it is still well to feed them for a time in this way.

Chicken-eating Cat (*Edith*).—We like a cat on our hearthrug, but we like our chickens more; so if our cat killed the latter, we should condemn the cat to a watery death. You could only save your chickens and the cat too by having the chickens within a wire enclosure—wired at the top as well as the sides.

Queen Laying a Plurality of Eggs in One Cell—Frame Hives (*Edward Fairbrother*).—We do not fancy that there was any defect in the unfortunate queen, which was merely impelled to relieve nature by depositing a plurality of eggs in every available cell, owing to the circumscribed breeding space to which she was restricted in so weak a colony. Could you once have succeeded in raising the population to a sufficient extent, we have little doubt that she would have proved herself fully equal to the occasion. We perfectly coincide with you in your appreciation of frame hives, and in considering that apiarians generally are indebted to Mr. Woodbury for making public and disseminating his modification of, and improvements upon, this German and American invention.

Artificial Swarms (*W. H. Steer*).—Do not attempt to equalise the population by reversing the position of the hives, as by so doing you would risk the loss of one or both the queens. We should not attempt to artificialise under such circumstances, but should prefer waiting the issue of natural swarms.

WEEKLY CALENDAR.

Day of Month	Day of Week.	JUNE 13—19, 1867.	Average Temperature near London.			Rain in last 40 years.	Sun Rises	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last forty years, the average day temperatnre of tho week is 72.3°; and its night temperature 48.5°. The greatest heat was 93°, on the 19th, 1846; and the lowest cold 30°, on the 15th, 1850. The greatest fall of rain was 0.84 inch.

HUMEA ELEGANS CULTURE.

FROM the stateliness of its growth, the graceful disposition of its silvery-brown plumes, and its agreeable fragrance, Humea elegans must be considered one of the most pleasing of decorative plants. Planted at the back of a border of bedding plants, dotted here and there in extensive arrangements of these, placed in the centre of a large bed, or grown as a specimen on a lawn, any shortcoming which it may have as regards showiness of bloom is more than compensated for by its distinctness of habit and elegance of form.

The plant was grown much taller (some say finer), fifteen or twenty years ago than now; one might then have seen Humeas with stems as thick as a Dahlia-stake, and quite as long, without so much as a leaf—wonderful were the Humeas of those days—but since then symmetrical plants well provided with foliage and bloom, without the disfigurement of a long bare stem, are the objects aimed at.

Those who cultivate the Humea should remember that it is a biennial; the moment the seed has germinated the tendency of the plant is towards flowering; it grows one year and flowers the next, being vigorous and compact, or tall and ungainly, according to the treatment. If tall "leggy" plants are wanted, then sow the seed in spring, keep the plants pot-bound throughout the summer, allow the foliage to flag from want of water, keep them as closely together as trees are planted in a coppice, and warm and at a distance from the glass in winter; but if you wish for fine plants with spray touching the ground or stretching beyond the rim of the pot, they must from the day they appear above the soil be kept gently progressing, must never flag from want of pot-room or water, and must have the same advantages as a specimen Pelargonium or Cineraria—namely, plenty of air, light, and room.

The seed may be sown any time during May, but from the 1st to the 15th is to be preferred. It is not, however, now too late to sow the seed, more especially for planting-out in the following year about this time. A pan a foot in diameter will be sufficient to grow plants for a large garden, and a shilling packet of seed will be ample. The pan should be well drained, and filled to the rim with fine soil, sifted through a half-inch sieve, an inch or so of the riddlings or rough portions being placed over the drainage, and then the fine soil. The compost may consist of two-thirds light loam, one-third leaf mould, and one-sixth of silver sand. Previous to sowing, the surface should be made quite smooth by patting it gently with the bottom of a flower-pot, and after the seeds have been scattered evenly over the surface they should be just covered with fine soil. A gentle watering must then be given, and the pan, having been placed in a hotbed, the soil should be kept shaded and moist. A Cucumber or Melon-frame, or any ordinary hotbed will do. The soil should be kept moist but not wet, and in a few days the plants will appear. The pan ought to be kept near the glass, and air must be given daily, and water when necessary. When the plants show their second or rough leaves, the pan should be placed near the glass in a cold frame, or, which will answer better, it may be set in a position shaded from the midday sun, and covered with a hand-glass, the top being put cross-cornerwise early every morning. Give a gentle sprinkling overhead at 4 P.M., and put on the top closely. If placed in a frame the pan ought to be shaded from bright sun in order to prevent the soil becoming dry, and air should be liberally admitted, but in the morning only, closing early in the afternoon after gently sprinkling with water overhead.

The plants will not appear to make much progress at first, but when one can take them between the finger and thumb, and with a stick lift them from the pan, pot them off singly in pots from 2½ to 3 inches in diameter, using the same compost as at the time of sowing, and set the pots closely together on sand in a cold frame. Give a gentle watering after potting, put on the lights, keep close, shade from 9 A.M. to 4 P.M., and at the latter hour give the lightest possible sprinkling of water, and shut up closely. In a few days the plants will recover; then admit air early in the morning, shade for an hour or two during the hottest part of the day, shut up closely by 4 P.M., and give a gentle watering overhead. Water should also be supplied in the morning, for the soil in the pots must be kept moist.

Under the above treatment the plants will grow rapidly and strongly. They must not stand still an hour: therefore when their pots are full of roots at once shift them into four-inch pots. Afterwards keep them in the frame, pursuing the same treatment as before, and in a fortnight they will have filled the pots with roots, and should have six-inch pots without delay, employing the same compost and affording the same treatment as before, only they must have room. These pots will soon be filled with a mass of roots, and now for a change of treatment. Tilt the lights back and front from 7 A.M. to 5 P.M., the lights being drawn on at the former hour and off at the latter. The plants will therefore be covered by the lights tilted over them by day and be exposed at night. Water overhead when the lights are drawn down, but before doing so water at the root if the soil is dry, using weak liquid manure if necessary. By the early part of August the plants will have hard balls of soil and roots; choose then an open situation, but sheltered from winds, and prepare a bed 1 foot deep in every way the same as for pricking-out Celery, using good loam enriched with a dressing of 3 inches of rotten manure and 3 inches of rough leaf mould. Give the plants a good watering before turning them out of their pots, and plant them in the bed in quincunx order at 1 foot apart every way; then well water them overhead at once, and afterwards whenever the weather is hot and dry; in such periods watering at the root must also be well attended to.

About the middle of September, and not later than the end of the month, the plants should be lifted very carefully with a fork, on a damp day if possible. Preserve the old ball entire, but shake away the loose soil; then place them in nine-inch pots, affording liberal drainage, and using a compost of one-third loam from rotten turf—that from a pasture where the soil is a rather strong yellow loam is to be preferred—one-third thoroughly decomposed cowdung, and a like proportion of rough or three-parts-decayed leaf mould, with the addition to the whole of about one-sixth sharp sand. The loam should be torn in pieces with the hand, the cowdung should be so dry as to be easily broken with a spade, the leaf mould ought to be passed through a three-quarter-inch riddle to free it from sticks, and all should be well mixed and incorporated. The soil must be well worked in amongst the roots, and the plants ought not to be potted deeper than they were before, or only very little. They may, after potting, be placed in a cold pit, a gentle watering and a slight syringing overhead being given, and the frame kept close and shaded for a few days until the plants recover from potting so as to endure sun and air without flagging. After they have become again established, air should be given very freely whenever the weather is mild, and protection must be afforded them by mats placed over the lights. They may remain in the cold pit or frame until the close of November, or even later if the weather be mild, when they should be removed to a cold and airy greenhouse, where they cannot have too light and roomy a position. The plants must be watered to keep them gently growing, in fact the foliage should not be allowed to flag; no water, however, is to be given until the soil becomes dry, then afford a watering sufficient to show itself at the drainage. This is the grand secret of watering, for it is positively injurious to water a plant when the soil is wet, and it is equally hurtful to allow it to droop from the soil being too dry. As regards temperature, it is sufficient during winter if the plants be kept from frost; even a few degrees below freezing with a dry atmosphere will be better than a few degrees too much heat. Protection from frost is all they require, and air on all favourable occasions.

In February the plants may be shifted into 12-inch pots, employing the compost already mentioned, and this is all the potting I consider necessary for subjects intended to be planted out in the flower-garden. Let the plants continue in a cool house until the end of March; then place them in a cold pit, and let them remain there until the end of May, giving air on all favourable occasions, and keeping them as cool as possible, but protecting from frost. Sometimes when I have had little room I have not potted them early in spring, but have fed them with liquid manure instead; but the plants were not so fine as those which had had a shift.

The ground where Humeas are to be planted should have a liberal dressing of manure and leaf mould, or holes, each sufficiently large and deep to hold a barrowful of the compost named for potting, should be dug for the plants. After planting give a good watering.

If specimens are required for the greenhouse or for other purposes, some of the most promising plants may, early in January, be potted in 12-inch pots and kept in a cool house. By the end of February they will have filled the pots with roots; they may then have a final shift into 15 or 18-inch pots, and at this potting the soil may be rougher but not richer, though the loam may be of a stronger nature. They should be carefully watered until the roots are working in the fresh soil, and may after February have a sprinkling of water overhead night and morning, but nothing approaching to a close atmosphere. Of air and light they cannot have too much, and they cannot be kept too cool so long as they are merely protected from frost. They must have plenty of room, and if inclined to grow on one side more than another the pot should be reversed, placing next the light that side of the plant which seems disposed to grow least. When they have filled the pots with roots they may have liquid manure at every alternate watering, and afford a liberal supply of water when it is required. If aphis appear fumigate with tobacco paper, and thrips may be disposed of in the same manner; but either of these insects attacking Humeas show the air to have been too close, warm, and dry. Keep cool, airy, and well watered.—G. Abbey.

Retinospora filifera.—The first-class certificate for this plant, which was exhibited on Tuesday, the 21st of May, was awarded to Mr. John Standish, of the Royal Nursery, Ascot, and not to Messrs. J. Veitch & Sons as was stated. Mr. Standish holds the entire stock of this splendid Conifer, which he is now sending out.

A VISIT TO LEIGH PARK.

I recently accompanied a friend to the gardens appertaining to Leigh Park, near Havant, Hampshire, the residence of W. H. Stone, Esq., M.P.; and amidst the varying lights and shades of an April day, passed a few hours most agreeably amongst the objects of Nature's handiwork which are met with there.

The neat little town of Havant, lying on the South Coast Line, about seven miles from Portsmouth, is easily accessible to holiday-seekers, and the attractions of the Park are fully appreciated in summer by visitors from miles around. The entrances to the place are from the Portsmouth turnpike road; that which afforded us ingress is about a mile and a half from Havant, and is provided with a handsome lodge, the architectural design of which is the first evidence of taste which attracts the eye of a stranger. After entering at this place, and following a carriage drive winding amongst "ancestral trees," we came to a slight wire fence separating the shrubberies and precincts of the mansion from the park without. Passing this, my attention was first arrested by a curious-looking building, of which the masonry, grey with age, proclaimed its antiquity. A most intelligent guide who accompanied us through the grounds informed us that this was the old library, the present mansion being a modern erection, and occupying a different site from that of the old house. The library is a beautiful octagonal building, and its eight oriel windows contain excellent paintings relating to the Staunton family, to whom the estate formerly belonged. The harmonious blending and richness of the colours in these windows is very attractive to the eye, and the skilful workmanship displayed in the carved surroundings enhances their beauty.

From near this place a straight path diverged towards the aquatic-house, where the Egyptian Paper plant (Papyrus antiquorum), Bullrushes of the Nile, interspersed with the blossoms of the Victoria regia and other water plants, displayed themselves in natural perfection. The gold fish here were remarkable for their tameness as well as beauty.

Leaving the aquarium we passed into the Orchid-house, which is connected. Here are many new and rare species of Orchids, some of which are very fine specimens. Of these most of the names have escaped my memory; but my attention was forcibly attracted by a profuse-growing Allamanda Schottii trained to the roof, which it traverses. Besides looking very ornamental, it excellently guards off the direct rays of the sun.

Leaving this house, and going westward of this range, we passed through two vineries and a Heath-house. In the latter the numerous varieties were most brilliant and lovely—so lovely, that in gazing on the beauty of the Australian plants I was reminded of those lines—

> "Another Flora there of bolder hues
> And richer sweets, beyond our garden pride,
> Plays o'er the fields."

I lingered amongst these charming plants, and shall always retain a pleasing recollection of the Heath-house at Leigh Park. Here a glass case 4 feet wide is connected, and extends the whole length of the west wall. This is made serviceable for many purposes as well as the protection of the trees on the wall from late spring frosts, and preventing the fruit from being damaged by heavy rains when approaching maturity.

Retracing our steps to the Orchid-house, and making our way through the entire range, we were next introduced to two more vineries, one of which contained coloured Grapes, all, I believe, of the Black Hamburgh kind, and admirably trained.

The Peach-house completed this range. Two other vineries were passed, and then we came to the pineries, consisting of four ranges, two of them lean-to's and the other two span-roofed pits. The two latter contained successions of fruiting Pines, all presenting a very healthy appearance.

Next we were shown a large and lofty stove, in which were fine specimens of flowering and ornamental-foliaged plants and tree Ferns—viz., two plants of Maranta Porteana, and also of Maranta zebrina, two handsome specimens of Cycas revoluta, Zamia Lehmanni, Philodendron pertusum, Musa Cavendishii, in fruit, Ixoras, &c. Among the tree Ferns were Dicksonia antarctica, Alsophila australis, Cyathea dealbata, C. me-

dullaris, and Cibotium princeps. Some seedling Gymnogrammas were also worth mentioning.

A propagating-pit was the next building we entered. This contained cuttings of plants of valuable species, all affording good evidence of their careful culture. We were then conducted along the back of the building, taking the orchard-house on our way; and passing by a side walk towards the east we entered the new kitchen garden. This has only been recently formed, but promises full well under the management of Mr. Young, the head gardener. It is three acres in extent, admirably laid out, and walled in, and the various crops are in a thriving state. There is a number of new pits for forcing vegetables, and Cucumbers and Melons were in a flourishing state.

Passing out of the kitchen garden, through the shrubberies, we soon arrived at the new carriage drive, on one side of which is a thickly-planted border of Rhododendrons, and on the other a neat plantation of choice Conifers on a well-kept piece of turf. We continued our walk along this winding and ornamental drive towards the mansion, which is about 350 yards north-west of the kitchen garden. A new conservatory, a lofty and imposing structure, graces the south front to the mansion. Being unfinished there is nothing worthy of remark here, save the extensive and lovely landscape which is opened to the view, bounded by the hills of the Isle of Wight, and with the sea in the foreground. Hayling Island is distinctly seen, and right and left is spread a panorama of picturesque scenery as beautiful as any in this country. A narrow spiral staircase conducts from this conservatory to a vaulted corridor, open to the west, on the lowest level of the west front. This is designed as a promenade on rainy days. From this corridor we passed on to the green turf before the house. It is an elegant edifice, very unlike the general massive and stately architecture employed in England. The style is pure Swiss, with all the gables and terraces prominent as in a mountain château.

Descending about 500 yards of gentle slope we came to the borders of a sheet of ornamental water. This miniature lake, three acres in extent, has an island in the centre nearly covered in the season with brilliant Rhododendrons. We were told that a former owner of the estate had a regular war sloop lying here completely rigged and manned, and a ruined fort is still shown on the island, which was made to resist mimic bombardments, for the amusement of a generation that has now passed away. There are various points of attraction in the grounds we traversed around the water, such as the rustic bridge connecting the island with the mainland, some rustic shady retreats, a very pretty grotto, and a rockery, where hardy Ferns were flourishing amongst early spring flowers.

Leaving this we ascended the hill towards the Conifer ground. Having gained one of the walks which wind through a part of the pleasure grounds, we passed one of the Rose gardens and along the south and west side of the fruit garden. Here we saw Camellias in full bloom trained to the wall. Not one of them had suffered by the severity of the late winter. We were now among the Conifers. All these are certainly worthy of remark individually, and the least that I can say is, that amongst others two magnificent plants of Araucaria imbricata may be seen there without a blemish in any tier from top to bottom; also, a Picea pinsapo, superior to any which I have seen in uniform growth and size. A few steps further brought us past another Rose garden to the old conservatory, the freshness and beauty of its tenants being unsurpassable, and the grouping and arrangement excellent.

Making such a hurried visit I had not time to pay attention individually to the various specimens of plant life with which this place is enriched.

Altogether Leigh Park is a very charming place; and as Mr. Young (to whose courtesy I shall always feel indebted), is continually making improvements, in which he is warmly supported by the owner of the estate, I have no doubt that in the course of time it will become one of the finest residences in England.—George Newlyn, *Dangstein.*

EFFECT OF FROST ON PITH OF ROSES.

I observe that your correspondents "D., *Deal,*" and Mr. Radclyffe, have alluded to the dark brown colour in the middle of the wood of many Roses, and it is a very interesting question why some trees were injured in the bark, and others in the centre of the wood. Can it be that the discoloration of the centre was the effect of the frost on the roots?

Three facts have suggested this explanation:—1st, The rods when pruned were mostly discoloured near their base, and were in many cases quite untouched towards their tips. 2nd, Those pruned in April were much more discoloured than those pruned in March, though of the same sorts and in some cases even on the same plants, from which I think we may conclude that the colour was connected with the rise of the sap. 3rd, I found some briars as much affected as the most tender Roses.

It would also be interesting to know what is the effect of the brown colour on the health of the plant. Some which I gave up as hopeless, have made thus far very vigorous shoots; while others which appeared at first more promising have withered and died.—E. H.

THE CLOUDS AND SUNSHINE OF ORCHARD HOUSE CULTURE.

I have been much charmed with the letter of your correspondent, "A Constant Reader," page 342, in which that great end is attained—instruction without dulness. How fatigued one often feels with some of our good gardeners because they cannot tell what they know without being constrained. I feel half ashamed to contribute my experience of orchard-houses something after the manner of our friend and instructor; it seems something like those authors who, after Cervantes, could never write a novel without a species of Sancho Panza in attendance on their hero.

Sunny.—My Cherry trees, all pyramids in pots, are crowded with fruit, from some of which I gathered ripe fruit May 24th. I have had a Cherry feast daily since, and shall continue to do so till the end of July. My earliest sorts, some of them now (June 3rd), dead ripe, are the Early Purple Guigne, Guigne Très Précoce, and Empress Eugénie. The trees are in 13-inch pots; they were top-dressed early in November by taking out the surface soil 4 or 5 inches in depth round the sides of the pots, and replacing it with loam and rotten manure.

Cloudy.—Some fine seedling Peach trees three and four years old in 11-inch pots, after blossoming abundantly and giving much promise, shed all their blossoms without setting any fruit. The cause I attribute to their roots being slightly injured by the severe frost in January. The pots were protected with hay, but not sufficiently to resist the severity of the frost of that month, when on the 5th the thermometer outside registered 28° of frost.

Sunny.—Some larger seedling Peach trees in 13-inch pots, and all my Peach and Nectarine trees budded on Plum stocks, are bearing fine crops. They were top-dressed early in November, were soundly watered a week afterwards, and remained dry all winter.

Cloudy.—Some fine standard Peach trees growing in the border of the house, and capable of bearing a peck each, shed their blossoms, and have set but very few fruit, while those mentioned in the preceding paragraph, in pots, and standing on the floor of the same house, are full of fruit. I am at a loss to account for the failure of the standard trees, as they are in the most vigorous health.

Sunny.—My numerous Apricot trees in pots are full of fruit. They have been treated according to the new rules given to us by Mr. Rivers in his paper written for the Congress last spring—that is, not top-dressing them in autumn as usual, but giving them a sound watering about the first week in November, and allowing the pots to remain dry till the first week in March; they are then watered; and in May, as soon as the fruit are the size of horse beans, the surface mould is scraped off to about 2 inches in depth, and a surface-dressing of finely chopped manure, or horse-droppings from the roads thoroughly saturated with strong manure water, is placed on the surface of the pots 3 or more inches deep, so as to be above the rim of the pot, and made concave to retain water. It is good practice to add malt combs to this compost. This dressing should be renewed in June and July if it settles down sufficiently. This is the grand secret of Apricot culture in pots under glass, and has never failed.

Cloudy.—Some fine old Apricot trees, which were top-dressed last October, and which blossomed abundantly, have set but a scanty crop of fruit. This top-dressing was an experiment. I am now quite satisfied that the new method is the best.

Sunny.—My pyramidal Pear trees in pots, which blossomed beautifully in my orchard-house in April, have set fine crops of fruit. I was sorely tempted to place them out of doors during the hot weather in May, thinking that summer had

arrived, but I resisted it, and thus escaped the lamentable frost of the 25th ult. I may add that I have been equally fortunate with my Plum trees in pots.

Sunny.—Mulberries in pots have a fine crop on them. Those out of doors are all destroyed by the late frost.

Sunny.—Expecting frosts on the nights of the 22nd, 23rd, and 24th of May, I had my ground vineries covered with mats. Not a sheet is touched, and there is a fine show of bunches. Vines on walls are much injured, and in some places the fruit all destroyed.

My orchard-house trees have been treated exactly as recommended in your columns and elsewhere, having had the soil renewed in autumn—with the exception of the Apricots referred to—and surface-dressed in spring and summer. Last April while the trees were in full bloom my house was open night and day, as the weather was mild and humid. I have found the treatment of my trees, as described in this article, attended with unvarying success. I mention this because your correspondent "C. P.," page 394, seems to have discovered a newer and a better way of treating his trees; for he says, referring to Mr. Rivers by name, "I have departed from his rules more and more every year with manifest advantage." This is a serious assertion, and I think Mr. Rivers and many of your readers will feel greatly obliged by his saying promptly how he manages his trees, and stating his climate and soil. We, your readers, have apparently something of consequence to learn, and I feel assured that Mr. Rivers will thank him for giving a fresh stimulus to orchard-house culture. —Hortulanus.

MANCHESTER NATIONAL HORTICULTURAL EXHIBITION.

Mr. Findlay's great undertaking may be looked upon as a grand success. We have only seen one exhibition to surpass it, and the Manchester people may well be proud of the success attending the efforts of the able Curator of their Botanic Garden in getting up an Exhibition very little inferior to the Great International Horticultural Exhibition held at South Kensington last year. Friday and Saturday were very unfavourable. The rain pouring down on Friday deterred many intending visitors from going to the Exhibition; but in the afternoon the weather cleared up, and the sun shone out brilliantly for an hour or so. Visitors to the number of three thousand then assembled to witness the grand sight prepared for them. Saturday morning opened more favourably, and the day continued very fine up to about two o'clock, when the rain fell again; but in spite of this a good company assembled, and towards evening the weather cleared up, and the number of visitors increased.

Roses were the only subjects which we thought were not so well represented as at Kensington last year; they were, however, very good. The Orchids were wonderfully fine. The splendid collections shown by J. A. Turner, Esq., were, probably, the finest ever seen at any provincial exhibition, and the magnificent groups of new and rare plants sent down by Messrs. Veitch & Sons attracted much attention. These were grouped on a circular stage in the centre of the Exhibition-house, and were seen to great advantage. On one side of them were arranged the designs for table decoration, on the other the fruit. For the time of the year, this was well represented. Mr. Meredith and Mr. Dixon were placed equal first for two bunches of Black Hamburgh. Mr. Meredith's, although much finer and better-grown bunches, were not so well coloured as Mr. Dixon's. We think the Jurors acted wisely in giving an equal first to both exhibitors. Mr. Dixon exhibited Grapes largely. He certainly proved at Manchester that he is capable of growing good Grapes, as well as writing a good book on raising Tricolor Pelargoniums.

On entering the Exhibition-house we were pleased to see a box of Ixias and Sparaxes; these were contributed by Mr. R. P. Ker, of Liverpool, and were very beautiful. It is to be hoped that this fine class of bulbs will become more generally grown. The collection exhibited on this occasion contained colours of every conceivable shade. Near it we observed a most beautiful plant, Anthurium Scherzerianum, as well as the curious Amorphophallus nobilis, exhibited by Mr. Bull, of Chelsea. The stove and greenhouse plants staged in the Exhibition-house were remarkably fine; those exhibited by Mr. Baines, gardener to H. Micholls, Esq., were especially good. Mr. Mitchell, gardener to the Duke of Hamilton, likewise exhibited fine collections; he had also a splendid collection of fine-foliaged plants, which, though they had travelled up from Scotland, were in excellent condition. Mr. B. S. Williams was an extensive and very successful exhibitor, his plants being in very fine condition. His collection of fine-foliaged plants was very beautiful, and so were his Orchids and stove and greenhouse plants.

At the conclusion of the labours of the Jurors, the Council of the Manchester Botanical and Horticultural Society and the Judges, sat down to an excellent cold collation in a tent in the gardens. In the unavoidable absence of the President of the Society, J. A. Turner, Esq., Sir J. Watts presided, and after the loyal toasts, proposed "Prosperity to the Society and the Exhibition." The Rev. Canon Gibson responded, and proposed "The Judges," coupled with the name of Mr. Mitchell, who replied in a very able and satisfactory manner. Mr. W. Thomson, of Dalkeith Palace Gardens, also made a very interesting speech, and endeavoured to impress upon the Council of the Society the necessity of giving greater prominence to fruit in their future exhibitions. This object, Mr. Thomson said, would be gained by offering better prizes. Mr. Thomson spoke in very flattering terms of the success of the Exhibition, and said, excepting the Great International of last year, it was the best he had ever seen. Mr. Thomson in the course of his remarks said that he thought the Manchester people were exceedingly fortunate in having in Mr. Findlay a gentleman so well able to manage their horticultural exhibitions, and although he had never seen Mr. Findlay before that day, he was very glad to congratulate him on his great success. Sir J. Watts gave the "Health of the Exhibitors," to which Dr. Ainsworth responded, and after speaking in high terms of the arrangements, thanked Mr. Findlay, on behalf of the Council, for the great exertions he had made, and said the Council would adopt the suggestions Mr. Thomson had offered them, and would in future offer more liberal prizes for fruit. Mr. B. S. Williams, of Holloway, also responded, remarking that he was the oldest exhibitor in London, and, therefore, he had had that experience which justified his saying that after the International of last year, this was the best flower show that had ever been seen. Mr. Williams, in the course of his remarks, said he hoped the gentlemen present, and others, would not allow the Manchester Botanical Society to remain any longer in debt; it was a disgrace, he said, to Manchester. He hoped they would put their shoulders to the wheel. He was willing to give, on his part, something towards it, and if they would only help him they might soon have a very flourishing society, free from debt and care. Other speakers followed, all expressing their gratification at the success of the Exhibition. The Chairman next gave the health of the Curator, Mr. Findlay, which was received with great applause. Mr. Findlay returned thanks in a very feeling and appropriate speech, in the course of which he said he thought there was nothing calculated to enlighten and elevate the minds of the inhabitants of large towns so much as horticultural exhibitions. The health of the Chairman was then given, and in returning thanks he very warmly commended Mr. Findlay for his origination of the Exhibition, and for the excellence of the arrangements which he had superintended.

The following is a list of the principal awards:—

AMATEURS.

Fourteen Stove and Greenhouse Plants, in flower—1st, Mr. H. L. Micholls, Bowdon; 2nd, Sir J. Watts, Cheadle; 3rd, the Duke of Hamilton.

Twenty Exotic Orchids, in flower—1st and 2nd, Mr. J. A. Turner, Pendlebury; 3rd, Mr. T. Jones, Whalley Range.

Eight Greenhouse Azaleas, in flower—1st, Mr. L. Hanmer, Woodford; 2nd, Sir J. Watts; 3rd, Mr. J. Stevenson, Lark Hill.

Ten Fine-foliaged Plants—1st, the Duke of Hamilton; 2nd, Mr. J. Stevenson; 3rd, Mr. T. Hobson, Wilmslow.

Eight Stove or Greenhouse Ferns—1st, Mr. T. Hobson; 2nd, Mr. J. Stevenson; 3rd, Mr. J. Broome, Fallowfield.

Twelve Hardy Ferns—1st, Mrs. Hampson; 2nd, Mr. W. Pearson, Prestwich; 3rd, Mr. J. F. Rowbotham, Chorlton-cum-Hardy.

Ten Zonal Pelargoniums, in flower—2nd, Mr. H. K. Balstone, Bowdon.

Ten Variegated Pelargoniums—1st, Capt. Starkie; 2nd, Mr. E. Phillipi; 3rd, Mr. J. Lees, Hawkwood.

Six Show Pelargoniums, in flower—1st, Mr. T. Agnew, Manchester; 2nd, Mr. J. Broome.

Six Fancy Pelargoniums—1st, Mr. T. Agnew; 2nd, Mr. J. Broome.

Six Rhododendrons, in flower—3rd, Mr. T. Hobson.

Six Amaryllis, in flower—1st, Dr. Ainsworth, Manchester.

Three Palms—1st, the Duke of Hamilton; 2nd, Mr. J. Broome.

Three Tree Ferns—1st, Mr. H. Micholls, Manchester.

Six Fuchsias, in flower—1st, Mr. H. K. Balstone; 2nd, Mr. W. Bindloss, Eccles; 3rd, Mr. W. Chittick, Bowdon.

Eight Stove and Greenhouse Plants, in flower—1st, Mr. J. Stevenson; 2nd, Mr. T. Kendall, Cheadle.

Eight Greenhouse Azaleas, in flower—1st, Sir J. Watts.

Twelve Exotic Orchids, in flower—1st, Dr. Ainsworth; 2nd, Mr. J. A. Turner; 3rd, Mr. T. Baker, Manchester.

Six Herbaceous Calceolarias, in flower—1st, Mr. E. Tootal, Weaste; 2nd, Mr. J. Keymer, Timperley; 3rd, Mr. R. Andrew.

Six Shrubby Calceolarias, in flower—1st, Mr. J. Keymer.

Four Greenhouse Azaleas, in flower—1st, Mr. L. Hanmer; 2nd, Mr. H. Micholls; 3rd, Sir J. Watts.

Ten Miscellaneous Plants—1st, Mr. S. Schloss, Bowdon; 2nd, Mr. T. Kendall; 3rd, Mr. H. Micholls.

Eight Exotic Orchids, in flower—1st, Mr. J. Stevenson; 2nd, Mr. T. Kendall; 3rd, Dr. Ainsworth.

Six Fine-foliaged Plants—1st, Mr. S. Schloss; 2nd, Mr. E. Philippi.

Twelve Miscellaneous Softwooded Plants, in flower—1st, Capt. Starkie.

Four Stove and Greenhouse Plants, in flower—1st, Mr. T. Kendall; 2nd, Sir J. Watts; 3rd, Mr. E. Philippi.

One Azalea, in flower—1st, Mr. L. Hanmer (Juliana); 2nd, Mrs. Hampson; 3rd, Mr. T. Kendall.

One Exotic Orchid, in flower—1st, Mr. T. Kendall (Saccolabium retusum); 2nd, Mr. T. Jones; 3rd, Dr. Ainsworth.

One Cape Heath, in flower—1st, Mr. T. Kendall (Erica ventricosa coccinea).

One Rhododendron, in flower—1st, Mr. L. Hanmer.

NURSERYMEN.

Twelve Stove and Greenhouse Plants in flower—1st, Mrs. E. Cole and Sons, Withington; 2nd, Mr. B. S. Williams, Holloway.

Six Greenhouse Azaleas, in flower—Mrs. E. Cole & Sons; 2nd, Mr. B. S. Williams.

Ten Roses, in flower—1st, Messrs. H. Lane & Son, Great Berkhampstead; 2nd, Mr. R. Ashcroft, West Derby.
Sixteen Roses, in flower—1st, Messrs. Paul & Son, Cheshunt; 2nd, Mr. J. Shaw, Bowdon.
Ten Show Pelargoniums, in flower—1st, Mr. H. May, Bedale.
Ten Fancy Pelargoniums, in flower—1st, Mr. H. May; 2nd, Mr. C. Rylance.
Twelve Exotic Orchids, in flower—1st, Mr. B. Williams; 2nd, Mr. J. Shaw; 3rd, Mr. S. Stafford, Hyde.
Eight Cape Heaths, in flower—1st, Mr. B. S. Williams; 2nd, Mrs. E. Cole & Sons; 3rd, Mr. J. Shaw.
Twelve Fine-foliaged Plants—1st, Mr. B. S. Williams; 2nd, Mr. J. Shaw; 3rd, Mr. S. Stafford.
Twelve Amaryllis, in flower—1st, Mr. B. S. Williams.
Thirty-six Hardy Ferns—1st, Mr. J. Shaw; 2nd, Mr. Ashcroft; 3rd, Mr. S. Stafford.
Twenty Hardy Rhododendrons, in flower—1st, Messrs. G. & W. Yates, Manchester; 2nd, Mr. J. Shaw.
Ten Hardy Rhododendrons, in flower—1st, Mr. J. Shaw; 2nd, Msssrs. G. & W. Yates.
Six Tree Ferns—1st, Mr. B. S. Williams; 2nd, Mr. J. Shaw; 3rd, Mr. S. Stafford.
Ten Zonal Pelargoniums, in flower—1st, Messrs. G. & W. Yates; 2nd, Mr. R. Barnes, Macclesfield; 3rd, Mr. J. Shaw
Ten Variegated Pelargoniums—2nd, Mr. R. Barnes; 3rd, Messrs. G. and W. Yates.
Twelve Miscellaneous Plants—1st, Mr. B. S. Williams; 2nd, Mr. J. Shaw; 3rd, Mr. S. Stafford.
Fourteen Greenhouse Azaleas, in flower—1st, Messrs. H. Lane & Son; 2nd, Mr. B. S. Williams; 3rd, Mrs. E. Cole & Sons.
Fifty Hardy Evergreen Trees and Shrubs—1st, Mr. J. Shaw, Bowdon; 2nd, Messrs. G. & W. Yates; 3rd, Mr. S. Stafford.
Fifty Hardy Alpine and Herbaceous Plants—1st, Messrs Dickson and Brown, Manchester; 2nd, Mr. S. Stafford; 3rd, Messrs. G & W. Yates.
Twenty-five New and Rare Plants—1st, Messrs. J. Veitch & Sons, Chelsea; 2nd, Mr. B. S. Williams; 3rd, Mr. J. Shaw.
Three Pots of Lilium auratum, in flower—1st, Mr. B. S. Williams; 2nd, Mr. J. Shaw.
Six Fancy Pelargoniums, in flower—2nd, Mr. C. Rylance.
Eight Yuccas or Beaucarneas, 1st, Mr. B. S. Williams; 2nd, Mr. J. Shaw.
Six Stove and Greenhouse Plants—1st, Mrs. E. Cole & Sons; 2nd, Mr. B. S. Williams.
Eight Dracænas and Cordylines—1st, Mr. B. S. Williams; 2nd, Mr. S. Stafford.
Ten Stove or Greenhouse Ferns—1st, Mr. B. S. Williams; 2nd, Mr. J. Shaw.
Six Roses, in flower—1st, Messrs. Paul & Son; 2nd, Messrs. H. Lane and Son.

FRUITS.

Ten Orchard-house Trees, in fruit, in pots—1st, Messrs. H. Lane and Son.
Two Vines, in pots—1st, Messrs. H. Lane & Sons; 2nd, Mr. T. Statter, Stand
One Queen Pine Apple—1st, Mr. T. N. Miller.
One Providence Pine Apple—1st, Capt. B. Glegg.
One Smooth Cayenne Pine Apple—1st, Mrs. Holland, Altrincham.
Two Bunches of Black Hamburgh Grapes—1st, Mr. T. Dixon, St. Helens, and Mr. J. Meredith, Garston, equal; 2nd, Capt. B. Glegg; 3rd, the Bishop of Manchester.
Two Bunches of any other Black sort—1st, Mr. T. Dixon; 2nd, Mr. H. J. Hopwood; 3rd, the Bishop of Manchester.
Two Bunches of Muscat of Alexandria Grapes, 1st, Mr. W. Chittick, Bowdon; 2nd, Mr. T. Dixon; 3rd, Mr. E. Greaves, Barford.
Two Bunches of any other White kind, 1st, Mr. T. Dixon.
Four kinds of Grapes—1st, Mr. T. Dixon, and Mr. H. J. Hopwood equal; 3rd, the Bishop of Manchester.
One Green-fleshed Melon—2nd, Mr. J. Meredith; 3rd, Mr. H. Littledale.
One Scarlet-fleshed Melon—3rd, Mr. W. Chittick.
Six Peaches—2nd, the Duke of Leinster; 3rd, Mr. R. O. Leycester, Knutsford.
Six Nectarines—1st, Capt. B. Glegg; 2nd, the Duke of Leinster; 3rd, Mr. H. J. Hopwood.
Six Dishes of Fruit—1st, Mr. H. J. Hopwood.

TOBACCO DUTY-FREE FOR GARDENING PURPOSES.

I HAVE noticed in your valuable paper one or two communications respecting ground tobacco and tobacco powder, and your correspondent "P. H. G." puts several questions, to which you will, perhaps, kindly permit me to reply. I am the more anxious to do this because I have been for some time in correspondence with the Government on the subject of duty-free tobacco, and the Company I have the honour to represent has spared no trouble or expense to induce the Lords of the Treasury to accede to the wishes of the gardening public. Indeed, if I mistake not, you noticed in your pages last year the efforts made in this direction.

Now, the boon spoken of by your correspondent "P. H. G." is granted, but under such conditions that it may be useful if I explain them as briefly as possible.

The Honourable the Board of Customs will permit the tobacco to be prepared only in a warehouse bonded according to the usual regulations imposed upon all bonded premises, and the process of grinding and mixing must be carried on under the direct superintendence of the crown officers. The tobacco so prepared has to be mixed with certain proportions of sulphur and assafœtida, and it can be issued to the gardener for use. The drugs are added by the Government to protect the revenue against fraud, by rendering the tobacco unfit for the purposes to which it is usually applied.

Of the advantages conferred by the Government in this concession I need say nothing, as the gardening public know the great value of tobacco.

On a former occasion the Government authorised our Company to prepare tobacco juice, and stipulated that the juice should be treated with logwood in order to protect the revenue, and this preparation also has been widely used by Hop-growers. —J. F. TAFE, *Secretary, Richmond Cavendish Tobacco Company, Liverpool.*

HARDY PLANTS IN FLOWER DURING APRIL, 1867,

AT BITTON, GLOUCESTERSHIRE.

April 1. Vinca minor
minor alba
minor fl. pl.
" 3. Anemone ranunculoides.
Narcissus aurantius plenus
Cypri
" 4. Adoxa moschatellina
Fragaria vesca
Lathræa squamaria
Oxalis acetosella
Draba aizoon
" 5. Almond
Crocus obesus
" 6. Plum
Double-flowered Peach
Kerria japonica
Pulmonaria azurea
Narcissus, Double Jonquil
Queen Anne's Jonquil
Macleayi

MR. JOHN WATERER'S RHODODENDRON EXHIBITION.

NOTWITHSTANDING the excessive cold of the past winter and the frosts of May, Mr. Waterer's display of Rhododendrons in the Royal Botanic Society's Gardens, Regent's Park, is as extensive and beautiful as in former years. It is just now in perfection; how long it will continue so we cannot venture to say, for it is to be feared that the present intensely hot weather will somewhat abridge the duration of the bloom. Conspicuous among the newest varieties is Michael Waterer, which has been exhibited under the name of Annihilator. This Mr. Waterer considers the best hardy late crimson variety known. Joseph Whit-

worth, deep purplish lake, is, as last year, remarkable for its large flowers and conspicuous anthers; Madame Masson, white, with orange spots, is pleasing; and Sir Robert Peel, crimson, is a very bright-coloured, free-blooming variety. Duchess of Sutherland, Mrs. Fitzgerald, Lady Alice Peel, Sidney Herbert, and Warrior, maintain their character as fine varieties. Most of the older kinds are well represented, and of these Bulleriannm, Bylsianum, Lneiferum, Lady Eleanor Cathcart, Mrs. John Waterer, Lady Godiva, and John Waterer, are very fine.

FRUITFUL VINES BECOMING UNFRUITFUL.

In the autumn of last year I took charge of a large vinery, and at that time it was crowded with young wood; likewise there were, I thought, too many canes, and a very heavy crop, the half of which ripened; the remainder shrivelled. The overcrowding I remedied by thinning out; and at the pruning season, each Vine having two leaders, I cut one off. The excessive crop I conjectured was too far advanced to do any good by thinning, consequently I allowed the bunches to remain. This spring all the buds readily started and have made strong shoots; but, much to my surprise, the trees have scarcely shown any fruit. They have had every necessary attendance, disbudding being duly practised, as soon as the shoots were of size to choose from. The Vines are planted in an outside border, and were watered in the first week in May. Can I do anything to enable me to have a few bunches this year? Would cutting back this year's wood to the first joint be of any service?—A Subscriber.

[Yours is a puzzling case. No doubt you did right in thinning-out the wood, and lessening the number of canes in winter, so far as the future welfare of the Vines is concerned; but you may have overdone the cutting off of shoots and wood, so far as the first season afterwards was concerned. At any rate, several times in Mr. Fish's practice, when he has lessened the space on the roof occupied by an old Vine, expecting it to come much stronger in consequence, he has found there was no improvement, perhaps the reverse, the first season afterwards, though in the second season there was a manifest improvement. There being less top branches to carry, the roots seemed at first to receive a paralysing influence from the want of the usual correlative action. In one case, some ten years ago, a very fruitful Vine yielded very little fruit the first season after such a severe lopping, but, as in your case, it made fine wood and bore well afterwards.

We attribute your want of fruit chiefly to two causes. First, the excessive crop left on the Vines, which would have a tendency to exhaust them as respects fruit-bearing; and, secondly, the wet and sunless autumn, unless fire was used, would be apt to leave the wood in an immature state, and this we are more inclined to believe, as the Vines show such vigour of growth this season.

As to what you propose, we would decidedly advise you to rest satisfied with the good wood the Vines are making, getting it well browned and hard by October, and to look for next season to repay you for your attention. We have known several cases of fruit being obtained by cutting back the young green wood of this season's growth to the first and second joint; but we never knew that to be done except under two circumstances. The cutting took place at the end of February or the beginning of March, on Vines that were started early, but did not show fruit to please; and then the pruning-back had to be applied to the whole Vine. If a few shoots were left unpruned they took all the growth; and the shoots made this year, when cut back, broke very weakly in consequence. Even then the Vines were greatly injured. Mr. Fish says that when a young man he helped to conduct a large experiment. Vines in a Pine-stove broke well and showed fairly, but the bunches almost wholly ran to tendrils instead of flowers. The roots were all outside. He attributed the evil less to a deep border than to the border being flat, if anything sloping to the house, to an unusually wet cold autumn, and to a severe frost, when the Vines had broken and the shoots were some 2 inches in length, there being nothing to protect the border. He always thought the chill and the want of action at the roots caused what would have been bunches to lengthen out into something like tendrils, on which the flower-buds that showed all shrivelled up or dropped off. The gardener, after much consultation and self-communings, pruned the Vines back in March just as proposed, and though fruit was obtained, it was neither abundant nor fine, and the wood was much weaker than usual. In fact, the sight of the Vines was quite sufficient to show that such pruning should not be done.

Mr. Fish adds, that a considerable amount of care had to be exercised to bring the Vines back to their original condition, and he recollects that in two or three cases the Vines showed scarcely any fruit after this second pruning, and in their case he selected the best shoot that came from near the base, trained it without stopping, and took off all the other shoots as it reached them, until about the middle of July the old stem was cut out altogether, and the one shoot then had all the strength of the Vine, and the following year this shoot showed abundantly, and fine bunches too.

Mr. Fish knows something of having two crops from the same Vines in the twelvemonth, but no one would think of this as a matter of prudence or economy. He has several times in pits cut back Vines in June that had borne a crop, selected a young shoot, and had it well ripened in autumn to bear early the following summer; but that is very different from what "A Subscriber" proposes. Had Mr. Fish pruned back such shoots on the Vines that bore fruit in June he would have had a fair chance for a late crop, though most likely he would have been deprived of an early one next summer; but the cutting of such ripe wood in June is different from cutting green wood that, it is presumed, did not start until March or April. His advice, then, is to make the most of the good wood for next season. Lest, however, "A Subscriber" is resolved to try, or some correspondents may give other advice, a circumstance may be mentioned in connection with the experiment already referred to, and which the gardener could not account for. Before he pruned back these unfortunate Vines the temperature of the house was considerably lowered for eight or ten days, and this was continued for about ten days afterwards, the temperature at night averaging from 50° to 55°, instead of from 60° to 65° and onwards, it being considered that this lower temperature for a time would do no harm to the Pines beneath the Vines. This was done upon the supposition that the Vines would break a second time better if they enjoyed a comparative rest. Afterwards Mr. Fish came to the opinion that it might have been better if the temperature had not been lowered, but kept at the usual rate before and after cutting. He cannot say that up to the present day he has quite decided on that point, but has no hesitation in advising "A Subscriber" to make the most of the present growth.]

THE CYLINDER OR TOWER VINERY.

This is a new invention by the originator of the ground vinery. The above form of vinery or plant case has been invented, not to supersede the ground vinery, which is a very neat, useful, and, if made after the plan of its originator, a very economical structure, costing as few shillings almost as pounds are being charged for it; but this I will enter further into in a future paper.

The cylinder vinery has many advantages. It stands erect, and thus all the beauties of the plant are seen. Sorts required to be thinned can be grown in such vineries. The plants become covered with dew in warm nights, if the top be left open. The continual circulation of air (resembling ebullition), without draughts, is an important feature. Light is in every direction admitted to the leaf and fruit. The plants are not subject to be infested by vermin of any kind. The whole structure is air-tight when closed. Air can be admitted at the bottom of the cylinder, but it has not been found necessary, a constant circulation being sustained by the warm air rising, and the cold air passing downwards. The structure is very light and novel; it can be made of any height, up to 15 feet, or more; it is very strong, from the scientific principle on which it has been constructed, and it is the cheapest of glazed structures.

I will now endeavour to describe it. The materials used are glass, wood previously boiled in creosote to render it indestructible, a few slips of iron, and a small quantity of rather stout copper wire, no putty or paint being used. The vinery can be erected in a few hours by any one of common intelligence. I will describe a structure of 10 feet in height and 11½ feet in circumference, capable of holding three Vines. For this six wooden bars 2½ inches square, and 12 feet long, are required, the glass being 20 inches by 15, 21-oz., fourth quality, costing about £1 2s. 6d. These bars (rendered as hard, and almost as heavy as ebony, by being boiled in creosote, which gives a brownish colour, and if taken out of the boiler hot becoming dry in a few minutes, are grooved to the depth of five-eighths of an inch at the two inner angles, the grooves being

so formed as to grasp the glass tightly. Each bar is driven 2 feet into the earth, and they are about 19 inches one from the other, so as to form a six-cornered figure, giving two sheets of glass 21 inches wide to each Vine.

In order to prevent the edges of the glass being too much pressed on by the glass above, and also to prevent the sheets being broken when the whole edifice is bound tightly by the copper wire, a very simple contrivance has been adopted—an iron bar of the same thickness as the glass, one-fourth of an inch wide, and one-eighth of an inch longer than the width of the glass, is forced down the grooves on to the glass. The copper wire being threaded through the wooden bars over the iron ones, is then drawn tight, and the structure becomes quite firm; but the cone is not fixed until all the glass has been inserted in the grooves. Instead of the iron bar being inserted on the last sheet of glass, a wooden one, 2 inches wide, makes a better finish. I have thus a firmly-erected, glass, six-cornered tube, 10 feet in height, and about 3 feet 9 inches in diameter, a light frame, in which four sheets of glass are inserted, forming the door. As there is no draught the heat accumulates to a great extent during the day. In one of these structures with slate at the north side, a thermometer (shaded) marked 99° Fahr.

These vineries are now being made of a conical form, on the same simple principle, when, perhaps, it may be found necessary to give air below. The heat given off from the earth at night, can be retained by having the wooden bars double-grooved and double-glazed, a stratum of motionless air being then enclosed. This extra expense would not exceed £1 10*s*.

The structure which I have endeavoured to describe would cost about £2 2*s*. This, for three Vines, is rather different from the £5 now charged for a ground vinery holding only one Vine, an expenditure never contemplated by the originator, and one which must be a complete obstacle to his system of growing Grapes for the million. I will shortly describe a structure made of indestructible materials, and costing only 14*s*.—A Looker-on.

TOWN SEWAGE.*

The book upon sewage by Mr. Krepp has been laboriously written, contains a description of almost all that has ever been attempted for the disposal of town sewage, and is in reality composed to advocate the system propounded by a Captain Liernur—a plan which in this work is elaborately described and illustrated by various engravings.

It was said of the critic Dennis that he was the fairest of critics, for he industriously pointed out what other poets should do in his reviews, and showed them what they should *not* do by his own poems. This remark well applies to the work before us. We here find an account of the chief sanitary attempts from Deut. xxiii. 13 to the present day—till Mr. Krepp arrives at his climax (p. 205), that "Captain Liernur's Engineering Agency is at 2, Royal Exchange Buildings, London, E.C."

Of that plan, which consists in the separation of human excreta from other sewage and its removal by carriages, it is needless to speak; no local board of health will ever dream of adopting so absurd, so impracticable a process. The far greater number of sanitary schemers forget that the removal of human excreta from populous places is only a portion of the great objects to be obtained by boards of health. Such persons do not consider—1st, that a more copious supply of water, which is in almost all towns required, leads to an increase in the amount of sewage—this must be provided for by sewers; 2nd, that the rainfall must also be conducted into the drains, and this rain water, which is rendered impure by the washings of the streets and houses, must also be provided for—it becomes a weak liquid manure, containing, besides other foreign matters, ammonia, and, in the case of granite-formed ways, a considerable portion of potash. This impure liquid must not be conveyed into the adjoining stream; it can only be sufficiently purified for its admission into a river by being previously employed in irrigation. If, therefore, it were practicable to separate the excreta from the other matters of town sewage, this would not obviate the necessity for sewers. They must still be constructed, and must also be regularly flushed by water. These requirements must all be considered by the sanitary improver. By separating the excreta from the other portions of town sewage as proposed by Captain Liernur, you would add largely to the expense, and add to the discomfort of the inhabitants.

As it has been observed in another place, such sanitary difficulties commence as soon as men begin to dwell in fixed habitations. As long as they live a wandering life they have little need to regard the refuse matters of their families, since they find it easy to often remove their tents to a fresh locality. When, however, men began to congregate, a different state of affairs arose. Of course the most primitive mode of disposing of such refuse matters was by throwing them into the street, a practice that to a very late period was adopted in some of our cities, a plan even yet followed in many of the plague-haunted cities of the East.

After a time, as towns increased in size, this disgusting practice gradually began to be superseded by another bad system. Cesspools were introduced. And now another very injurious sanitary effect was very slowly discovered. These cesspools could only be useful by being constructed in a porous soil, and lined with bricks without cement, so that the sewage daily poured into them from the houses could soak away into the soil. The result was, that the sewage very speedily descended into the earth until it reached the water-bearing stratum, from which the house-well obtained its water. Thus the water used for domestic purposes became tainted, and was in fact only a very diluted filtered sewage. The earth through which that sewage flowed in its way to the well (as was then but very little understood), merely removed the mechanically suspended matter, but not the chemically combined substances of the foul stream.

Then came the period, about a quarter of a century only since, when these facts were vigorously explained to the public at large. Long before this time, however, sewers had been constructed, even as early as the ages of imperial Rome; but they were only partially used by the citizens, were conetructed upon very erroneous principles, and emptied their noxious streams into the adjoining river, such as the Tiber, or the Thames.

Then came the days of the Public Health Act in 1848, when good sanitary principles began to be better understood. Sewers of a better character were then made; the sewage of various towns was completed; the sewage of the district was conducted to a common outfall, and that point was too certain to be at the bank of the adjoining stream. A new and very important difficulty now presented itself: the large mass of sewage thus for the first time collected and poured into the river rendered the stream too noxious to be endured by those dwelling on its banks. Courts of Equity were, therefore, speedily applied to; injunctions were granted, and in consequence boards of health were compelled to try and abate the nuisance. Here other mistakes were speedily made by those who were honestly endeavouring to benefit their fellow-creatures. It was deemed possible to deodorise the sewage before it reached the river. A small flight of schemers soon made their appearance, each with a plausible plan. These comprehended every possible variety of modes—settling tanks, filtering machines, precipitants, deodorisers, and combinations of two or three of these. The fate of these has been uniform: they have been and will be all failures. They neither accomplished the object sought to be obtained, nor, if they had done so, would they have been otherwise than a costly and needless expense to the inhabitants of the sewered districts, to say nothing of the utter waste of fertilising matter which they all involve. Several of these plans were carefully tried at the town of Croydon; but after every effort had been made, recourse was had to the employment of the sewage in irrigation. This plan, first adopted by the Local Board of that town, is now being successfully adopted by other populous places. It possesses the great advantages of being not only effectual, but of more than paying its necessary expenses.

It is, indeed, idle to assert that the use of sewage in grass irrigation is profitless; for when we know that the fields of Edinburgh let for £25 to £30 per acre, that the four hundred acres of sandy land at Mansfield (once let at 2*s*. an acre), have been converted by the Portland family into the richest grass land in Nottinghamshire by watering it with the sewage of Mansfield; when we further learn that the sewage-irrigated alluvial soil of Croydon produces annually at least thirty tons of grass, and that thirty-six acres of land on the London basin clay at Norwood, in the same district, yield a still larger amount of grass, it is useless to deny the fact that the irrigation system is successful and profitable. In adopting that system the error must be carefully avoided of applying the sewage to the land

* "The Sewage Question: Being a General Review of all Systems and Methods. By Frederick C. Krepp." Pp. 205, royal octavo. London, Longmans & Co. 1867.

in insufficient quantities. It is almost only to grass that the application is valuable, and to grass the quantity most successfully employed is annually from 3000 to 5000 tons per acre. The ground, indeed, must always be kept in a state of great moisture; the habits of the grasses must be, as it were, changed; an artificial demand for food must be created in the plant, and constantly supplied, and this is materially interfered with if the soil is allowed to become as dry as in its natural state. We must not forget that when we apply, say, 3000 tons of sewage to our land, this is only equal to a fall of rain of 30 inches, and this is about the actual difference in the rainfall between the western or grass-growing side of our island and the eastern or corn-producing side.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Amaryllis pardina (Leopard-spotted Amaryllis).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia. "A truly magnificent plant." Native of Peru. Found by Mr. Pearce, Messrs. Veitch's collector. Flowers yellow, densely studded with scarlet spots.—(*Bot. Mag.*, *t.* 5645.)

Bletia Sherrattiana (Sherratt's Bletia).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. "Perhaps the prettiest of the Bletias." Native of New Grenada. Imported by Messrs. Low. Flowers rosy purple; lip striped with yellow.—(*Ibid.*, *t.* 5646.)

Billbergia sphacelata (Withered Billbergia).—*Nat. ord.*, Bromeliaceæ. *Linn.*, Hexandria Monogynia. "Very handsome, conspicuous for its magnificent crown of leaves, each from 4 to 5 feet long." Native of Chili, near Conception, where it is called *Chupon*. Its fruits, sweet and pulpy, are called *Chupones*, and are the delight of the native children. Flowers lilac.—(*Ibid.*, *t.* 5647.)

Stemonacanthus Pearcei (Mr. Pearce's Stemonacanthus).—*Nat. ord.*, Acanthaceæ. *Linn.*, Didynamia Angiospermia. Named after Mr. Pearce, collector for Messrs. Veitch. Native of Bolivia. Flowers scarlet.—(*Ibid.*, *t.* 5648.)

Dendrobium macrophyllum, *var.* Veitchianum (Veitch's Large-leaved Dendrobe).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Java. Found by the late Mr. Lobb, Messrs. Veitch's collector. Flowers greenish yellow; lip streaked with purple.—(*Ibid.*, *t.* 5649.)

Scilla sibirica.—Dark blue.—(*Flore des Serres*, 1677.)

Ranunculuses.—Six varieties.—(*Ibid.*, 1679.)

Crocuses.—*Omer Pacha*, white, purple-edged. *Grand Jaune*, yellow. *Scottish*, white, crimson lines. *Mammoth*, very large, ivory white. *Drap d'Or*, yellow, crimson streaks. *Louis Napoleon*, very large, crimson purple. *Albion*, white, tinged and streaked with crimson. *Le Nuancé*, ivory white, crimson base. *Argus*, white, crimson-feathered. *Mont Blanc*, white. *Beranger*, lilac purple.—(*Ibid.*, 1680-1.)

Single Tulips.—*Junger Gelber Prinz*, yellow. *Jagt van Rotterdam*, white, crimson flakes. *Pottebakker blanc*, white. *Camelcon*, sprinkled with scarlet. *Matelas rose*, crimson, white-edged. *Dorothea*, white, crimson-flaked. *Grootmeester van Malta*, white, crimson-flaked. *Gouden Standard*, yellow, crimson-flaked. *Ville de Haarlem*, white, slightly flaked with purple.—(*Ibid.*, 1682-4.)

Double Tulips.—*Couronne de Roses*, crimson, white-edged. *Gloria Solis*, scarlet, yellow-edged. *Mariage de ma Fille*, white, crimson flakes. *Regina rubrorum*, yellow, crimson flakes. *Rex rubrorum*, deep crimson.—(*Ibid.*, 1685.)

Single Early Tulip.—Flower crimson, white-edged; leaves yellow-edged.—(*Ibid.*, 1687.)

Cattleya citrina (Yellow-flowered Cattleya).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Mexico. Flowers yellow, lip streaked with orange.—(*Ibid.*, 1689.)

Scutellaria costaricana (Scutellaria of Costa Rica).—*Nat. ord.*, Labiatæ. *Linn.*, Didynamia Gymnospermia. Introduced by M. H. Wendland, from Costa Rica, in Mexico, where it grows at an elevation of 6000 feet. Flowers scarlet with orange throat.—(*Ibid.*, 1690.)

Maranta illustris.—Leaves with white zone, purple under-surface.—(*Ibid.*, 1691.)

Magnolia Lennei.—A cross-bred between Yulan and purpurea, and named after the Director-general of the royal gardens of Prussia. Flowers pale rose, edged with white.—(*Ibid.*, 1693.)

Cratægus oxyacantha coccinea flore-pleno (New Double-blossomed Crimson Thorn).—"As a hardy ornamental tree for planting in the shrubbery and flower garden, we loop upon this Thorn as the grandest acquisition that has been obtained for many years; and as a forcing plant it is equally desirable, for the young plants appear to flower freely when only a few inches high. This, indeed, has been sufficiently shown by the examples which have been exhibited by Mr. W. Paul at the Royal Horticultural Garden, South Kensington, and at the Royal Botanic Garden, Regent's Park, several times during the spring of the present year.

"As there has been some doubt created in the mind of the public as to whether there are not two new double Crimson Thorns, issuing from different establishments, under similar names, we are glad to be able to dispel the mystery. We speak advisedly when we say that the plants shown by Mr. William Paul, and the branches shown by Messrs. George Paul & Son, are identical both in leaf and flower. The variety is a sport from the double Pink Thorn, and originated in the beautiful and well-kept garden of Christopher Boyd, Esq., of Cheshunt Street, near Waltham Cross, where it still exists. It has, therefore, never been the exclusive property of any one nurseryman.

"The history of the sport is briefly this: About seven or eight years ago some flowers of this intense hue were observed on a plant of the double Pink Thorn, and on examination it was found that a strong branch had started up from near the centre of the tree, with leaves as well as flowers differing from its parent. The branch was encouraged, and year by year increased in size, retaining the colour and character originally observed. The parent plant is apparently about twenty-five years old, 30 feet high, and as much in diameter, measured from the outermost branches at its greatest width. There is still only one stout central branch of this deep colour; the other branches, which are profusely adorned with flowers, being of the original pale pink so well known to horticulturists. When looking at the tree recently, so great was the contrast between the sport and the original, that we could not rid ourselves of the impression that the parent variety was in this instance paler than usual, and we asked ourselves whether the colouring matter had not been drawn from the larger surface and intensified in this particular branch by one of those secret processes which the student of Nature is often called upon to behold and wonder at, without being able to account for or explain. This may be fanciful, but here is certainly a *lusus naturæ* worthy of the attentive consideration of our vegetable physiologists.

"We do not hesitate to advise every one who has a garden, to purchase this plant at once."—(*Florist and Pomologist*, vi., 117.)

DESTROYING WORMS BY CORROSIVE SUBLIMATE.

Can you inform me the proper quantity of corrosive sublimate per gallon to dissolve in water in order to destroy worms in lawns? I have tried it during the evening on a small piece of grass, and the number of worms it brought out was surprising. The quantity used was about as much as would lie on a sixpence to a six-gallon watering-potful of water. Do you think this is strong enough to injure the grass?—Philip Crowley.

[The quantity of the virulent poison you employed would not injure the grass; but birds or poultry swallowing the worms would be injured or killed. One ounce to fifteen gallons of water is the quantity usually employed. Lime water is as efficacious as the solution of corrosive sublimate, and involves no danger. We are of the number who think it is better to disperse the wormcasts every morning with a broom, than to destroy the worms. We are of opinion that those wormcasts, and the admission of air to the interior of the soil by the holes made by the worms, are very beneficial to the grass.]

NOTES AND GLEANINGS.

We are requested to state that the following error was published in the advertised prize list of the Royal Horticultural Society's Show in our last number. In class 7, for six new Roses not sent out previous to 1864–5, in any sized pots (open), it was announced that Mr. William Paul obtained the first prize; whereas the first prize was awarded to Messrs. Paul & Son, and the second prize to Mr. William Paul. In our reporter's original report his notes were correct, and at the last moment, when he saw the official prize list, he altered his

own report, being unaware that any change in the prize cards had been made. That change was unauthorised and erroneous.

—— The Council of the Royal Horticultural Society, with the consent of the exhibitors, determined to extend the time of keeping open the Great Show to Whit-Monday and Tuesday to allow holiday-folks an opportunity of seeing such a magnificent display, and this concession was taken advantage of by a large number of persons. The attendance of visitors during the Show has been as follows:—Tuesday, June 4th, 5060; Wednesday, 1154; Thursday, 3351; Friday, 3107; Saturday, 1964; Monday, 3826; Tuesday not yet ascertained.

—— According to the "Journal of the Society of Arts," the following prizes were adjudged to gardeners at the final examinations, conducted under the auspices of the Society. The first prizes for Botany and Floriculture, of £5 each, were awarded to Robert Creaser Kingston, aged 20, Richmond Parochial Library and Reading Room, gardener. The second prize of £3 for Floriculture, was allotted to William Pritchard Roberts, aged 27, Bromley Literary Institute, gardener. The first prize for Fruit and Vegetable culture, £5, was adjudged to John Charles Higgs, aged 26, Southampton Athenæum, gardener; and the second prize to George Stanton, aged 26, Slough Mechanics' Institute, gardener. The Royal Horticultural Society's prizes were awarded as follows:—In Botany: first prize, £5, to Robert Creaser Kingston, 20, Richmond Parochial Library and Reading Room, gardener. Second prize, £3, Richard Lee Keenan, 23, Richmond Parochial Library and Reading Room, gardener. No other candidate qualified to receive a prize. In Floriculture: first prize, £5, Robert Creaser Kingston, 20, Richmond Parochial Library and Reading Room, gardener; second prize, £3, William Pritchard Roberts, 27, Bromley Literary Institute, gardener. In Fruit and Vegetable culture: first prize, £5, John Charles Higgs, 26, Southampton Athenæum, gardener; second prize, £3, G. Stanton, 26, Slough Mechanics' Institute, gardener. The "Gardeners' Chronicle" Prize of £3 is awarded to Robert Creaser Kingston, 20, Richmond Parochial Library and Reading Room, gardener.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Prepare ground for planting out Brussels Sprouts, Borecole, Broccoli, Cauliflowers, and Savoys. *Peas*, sow Knight's Marrows; if dry weather continue, the drills for Peas, Kidney Beans, &c., should be rendered moist before sowing, and if the seeds are previously steeped in water for eight or ten hours rapid vegetation will be insured at this period of the season. *Turnips*, take advantage of the first cloudy weather to sow a portion of the main crop of winter Turnips. They should be sown in drills whilst the ground is freshly prepared, placing in the bottom of the drill a compost of rotten dung, in order that roots may be emitted at once, and that the plants may form rough leaves sooner, so as to be out of the reach of the fly.

FRUIT GARDEN.

Particular attention will now be required with regard to wall trees planted last season. In the case of Pear trees it will be desirable that a central shoot be trained upright, and one on each side to form the lower tier; but in order that the latter may acquire greater vigour, they should not yet be brought to a horizontal position. If they appear of equal strength, they should diverge at the same angle, but if unequal the weaker should be allowed the greater elevation. The lowest side shoots of Peach and Nectarine trees should also be encouraged by as much elevation as can be afforded, consistently with the possibility of bringing them to their ultimate position, that of an angle of about 45° for a little distance from their origin, and then nearly horizontal. If the central shoot exhibit too great luxuriance, its point may be inclined to either side; a few of its laterals may yet be permitted, lest by stopping them the lower eyes should break prematurely. Disbud Figs, retaining no more wood than is required for the next season. Be sure to select the short-jointed wood.

FLOWER GARDEN.

Attend to the tying-up herbaceous plants that are tall or showing flower, such as the different kinds of Rockets, Pæonies, double and single Lychnis, &c., in order to prevent their being injured by the wind. Take up Anemone pavonina as soon as the foliage begins to die off, clean the roots, and store them away in an airy cool shed or loft to dry. Collect seed of the Poppy Anemone as it ripens, and sow it at once in a seed-bed; the plants will bloom next season if seed is sown during this month. Dog's-tooth Violets will succeed well if taken up, parted, and replanted as soon as the foliage is matured. Mow lawns often during this growing weather. Hoe and rake borders; remove dead leaves and blossoms, and water any of the recently-planted beds in which plants have not taken sufficient hold of the ground. Verbenas, Petunias, and similar plants should be pegged down where it is requisite to cover the surface of the beds. Fine specimens of Fuchsias may be planted out on lawns, also large Pelargoniums, chiefly of the scarlet kinds, and should be well staked. Ten-week Stocks may yet be sown for a display in September and October, and a little late Mignonette, as also a few of the best annuals for autumn work. Ranunculuses are in bloom in early localities, shade from the powerful rays of the sun, and occasionally water with soft water between the rows. Look sharply after a green caterpillar exactly the colour of the stem. It will generally be found just under the blooms. Pinch off the laterals, and thin the buds of Pinks, in order that those intended for exhibition may increase in size. Water those grown in pots during the evening, and tie with waxed thread the pods of those which are sufficiently advanced. Carnations and Picotees will now require considerable attention, examine the ties and see that no stems are pinched or contracted; continue to fasten others as they elongate; remove laterals, and use every means to encourage robust growth. Pansies for exhibition should have a slight awning over the bed.

GREENHOUSE AND CONSERVATORY.

Now is the time to encourage a rapid and sturdy growth in Corræas, Epacrises, Pimeleas, Chorozemas, Leschenaultias, Polygalas, Ericas, &c. A constant stopping of gross shoots will be necessary, in order to equalise the sap, and encourage the lower part of the plant. Let liberal shifts be given during the season, in order that the pots may be tolerably well filled with roots before the approach of winter, thereby guarding against stagnation in the soil. As a general compost for the most of these tribes, we would recommend three parts of a fibrous heath soil in a lumpy state, and abounding in sharp grit, to one part of a free turfy loam; a good sprinkling of charcoal from the size of a Pea to that of a Broad Bean, with a portion of pounded crocks of similar size, should be added to the mass. It is hardly necessary to urge the necessity of thorough drainage; let it, however, be thorough. Crocks carefully placed to provide outlets for the water, and these again covered with a smaller size of pounded crocks and charcoal, and finally with the roughest part of the compost, to place the ball on, will be found, although apparently troublesome at first, to be by far the least so in the end. This mode of arranging the parts of a compost, as also the drainage, will be found very essential, if not absolutely necessary, where liquid manure is constantly used. Cinerarias done blooming may be cut down, dipped in tobacco water to clear the aphides, and turned out into a raised bed in the kitchen garden or reserve ground; they will produce an abundance of suckers by the end of August, and may then be increased.

STOVE.

The principal work in this house is to attend to the climbing plants; see that they are all properly trained either to stakes or trellises. Some of them may require stopping to cause them to throw out a greater profusion of shoots. The beauty of these useful plants depends much on the training which they receive during the period at which rapid growth is going on; many of them are ruined owing to the want of timely attention in this respect. Keep down the green fly by fumigation, the red spider by syringing, and the mealy bug with the finger and thumb. The thrips, one of the worst of enemies to gardeners, may be subdued by constant smoking, and occasionally syringing with lime and soot water in a perfectly clear state; but this, and all other insects, when once they make their appearance, must be followed up in right earnest until they are completely destroyed. Where a great amount of heat is indulged in to promote the rapid growth of Orchids, some of the Guatemala kinds, the Lælias, and those from cool and mountainous regions, should be separated, if possible, from the main stock. A vinery in which a trifling amount of heat is kept up would do. Abundance of moisture in the atmosphere must, however, be provided.

PITS AND FRAMES.

Put in cuttings of the most choice kinds of Phloxes or other herbaceous plants, in order that they may be rooted before the frames are again required for autumn cuttings. Shade during the day, sprinkle and shut up early in the afternoon.

FORCING-PIT.

The young stock of Gardenias are the chief occupants here,

and now begins the propagation by grafting of Camellias, Rhododendrons, and Azaleas; when expedition is preferred, these may be kept in a strong, moist, and close heat till they are united, but they will do perfectly well in a close cold frame, well shaded, only they take longer time in this way.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The routine has been very much the same as last week—hoeing, planting, and taking means to forward crops that were injured by the frost. Pricked out plenty of *Celery*, and fully exposed what will be the first crops, as we have not yet manure at hand to plant in the trenches, or, rather, three-rowed beds, but we shall be able to attend to that presently. One advantage of planting large plants with good balls is, that the base of the plant can be examined, and everything like subsidiary shoots or suckers removed before final planting. When the plants are turned out young this dressing must, in a great measure, be done after they have grown in their allotted places, and with much more trouble than at planting-time. Large plants with good balls can be moved without the necessity of taking away a leaf, except with these axillary shoots or suckers. Although in very sunny weather the plants may require an extra sprinkling overhead, this, even, will not be necessary if they can have the flickering shade of staked rows of Peas between the beds.

Cauliflowers that were brought forward under hand-lights, and a good portion of which still remains, were finally banked up by digging a trench between the rows where the glasses were, and then for keeping them moist enough at the roots they were well banked up with short grass. They are much benefited by this mulching, especially when on a bank sloping to the south. Looked after succession crops, pricked out seedlings, and sowed for the last crops out of doors. We have had good returns by sowing in the beginning of July in patches, and allowing the plants to remain without transplanting; but the middle of June is late enough when they are to be transplanted. In small gardens there must be frequent sowings of everything to keep up a supply and have nothing to run to waste. Until the last sowing of Turnips it is advisable only to sow a small space at a time, and then the crop is always young, sweet, and tender.

Cucumbers.—Regulated those on a ridge intended for Gherkins, &c., also Vegetable Marrows. Banked up the linings of those in frames by placing short grass and a little litter above it, pretty well as high as the frames. The linings, properly speaking, have never been meddled with. The beds were made so much wider than the frames at first as to admit of this banking-up above the level of the bed, as it were, and thus heat is thrown in by forcing the wood to be a conductor, and there is no danger of too much bottom heat. These frames are so shallow that the soil inside is below their lower edges, except where some is beaten firm all round the insides to prevent any access of deleterious steam.

When such material as that referred to above is used for banking-up, care must be taken in giving air, to prop up the sashes, instead of sliding them up or down. The propping-up system is always the best in every way, and should always be adopted where there are linings of fermenting material. The fumes from rank dung will destroy a bed of Cucumbers as effectually as burning sulphur among them would do.

As soon as we can, we will take the soil from a bed that did good service for early Potatoes, remove a foot or more of the upper tree leaves, &c., mix dung from stables and short grass with the lower layer, replace that taken off, as well as the old soil, add a quantity of fresh, put frames on, and plant with strong Cucumber plants for succession, either to ease or take the place of those bearing freely as yet. There are so many casualties that may come, that it is best to be ready.

Cucumber Disease.—This either in its gummy secretion, or curled or spotted leaf, we are as yet free from; but in answer to many inquiries, we must say that we neither know what brings these evils, nor what will keep them away, as we had them for several years, and under every imaginable condition—in pits heated by hot water, in dung-beds, on ridges, in the open ground, it mattered not where, in what soil, or in what temperature. We even sowed in warm places out of doors, in the Sandy fashion, but it was of no avail; by the time the plants began to be useful they showed signs of the disease, and our only partial remedy was frequent sowing, using seed from a distance, and fresh soil each time. Now, we mention this prominently here that it may attract the attention of all who have suffered, particularly of any one who has discovered a remedy, and more especially because one of the best Cucumber-growers in the country, whose house, pits, and frames, used to be remarkable for the fertility and health of the plants, and who never had anything of the sort before in a long practice, has it now among all his Cucumbers, and he says he feels powerless to arrest its progress. Like ourselves, he is not aware of any difference as to treatment, soil, &c., and we had worked at least a quarter of a century among Cucumbers without ever having anything to do with such troublesome pests. At present we would venture to state, that the gardener who is thus troubled is to be pitied rather than blamed. We know there are many who make light of all this, but if they only once have a visit of the enemy, as our friend referred to has, they will find it too serious to make sport of. Who will make known a remedy for this evil?

Potatoes Diseased.—It is only right to mention another evil, as to the cause of which we are forced to confess our ignorance. This season early crops in pots and in frames have been very good. We mentioned planting a wide earth pit, with just a little heat at bottom, heat given by tree leaves, &c., not higher than 80° when highest, the heat in the soil ranging from 50° and a little more when highest; soil a rather light sandy loam. The Potatoes had been set on leaf mould in shallow boxes, and were sprung about 3 inches when planted. The rows were 18 inches apart, and there was nothing between them. Up to May nothing could look better, stems thick and sturdy, foliage of a dark green, and on examining them with the fingers several times the young Potatoes were found coming all right. All at once, after a thunderstorm followed by some days of bright sunshine, the tops showed signs of distress. On examining the soil we found it was in a healthy state, neither wet nor dry; but to keep the plants in a healthy growing state we gave them a slight watering, which revived them until the next fierce sun, when many of the tops flagged again. On examining more closely those that flagged, we found that a little below the surface of the ground the underground main stem was a mass of rottenness, and on these the young tubers progressed no more. On taking up what was thus, contrary to our expectations, a scanty crop, the soil if anything was dry, sweet, and friable, just the very opposite condition to that which would encourage rottenness. On many of the stouter stems thus decayed below the ground, there had been an attempt to throw out fresh roots and runners near the surface. The Potatoes taken from plants that escaped this infliction were good, clean specimens. Another puzzling circumstance is, that one end of the bed is still perfectly healthy, and is well supplied with good tubers, though treated in every way exactly as the rest, with these differences—This part was planted a fortnight or three weeks later, and whilst the earlier part consisted chiefly of varieties of the Ashleaf, the second, and as yet sound part, consisted chiefly of Early Frame and Prince of Wales. The latter was merely tried and promises well, though the stems are rather luxuriant for this system of early growth. The sets of the Prince of Wales were not home-saved. On some of the decayed stems we found a few small worms, &c., but, as it appeared to us, they came as the result and not as the cause of decomposition. There was no appearance of fungus of any kind—in fact, that was partly guarded against by mixing a little quicklime with the soil and forking it over several times before planting. Before this giving way of the underground stems no plantation could have looked more robust and healthy, for they had plenty of air except in very cold weather. Who will help us to account for a lot of the earliest planted thus suffering, and the later planted escaping under precisely similar circumstances in other respects? Have any of our readers noticed similar manifestations? Fortunately, though our general crops of Potatoes out of doors suffered a little from the frosts, those at the foot of walls escaped and are tubering well.

Proceeded with thinning Carrots, Parsnips, and Onions, hoeing the ground at the same time; the thinnings of the Onions, put in thickly, will do for salading and for forming small buttons. Carrots sown now will yield rich sweet pullings in autumn. Planted out Beet, as for years we have found it folly to sow, as it would require fine netting to keep the birds from it just as it comes through the ground. They are quite as destructive to the coloured young leaves of Prince's Feather and Love-lies-bleeding; but once the leaves have grown a little they cease to meddle with them.

FRUIT DEPARTMENT.

Nipping, thinning, watering, looking after insects, as detailed in previous weeks' notices. Nipped the stronger forcright

shoots from Pears, Apples, Plums, &c., so as to give more light to the smaller stubby sheets, and were careful not to overdo this nipping just yet, that there might be no inducement to these stubby spurs to elongate into shoots. By thus carefully summer-nipping our dwarf trees there will be no lack of fruit-buds, if the roots are in good condition, and the trees are kept compact and near home.

Melons.—"Frutex" wants to know if he cannot grow Melons in a cold frame after the middle of June, and also how best to manage the training and pruning in the simplest way. To the first we say, Yes. We have had good crops merely with a frame over them and no bottom heat, but taking care to secure all the heat possible from the sun, by shutting up closely early in the afternoon, and covering the glass in cold nights. The crop will be all the more sure if there be, beneath the centre of each light, two or three barrowloads of hot dung, on which the soil must be placed and firmly trodden. If it can be managed, the plants will do as well if the roots be confined to from 2 to 3 feet in width of soil, as over-luxuriance is thus avoided. The soil, however, should be 18 inches deep. We shall describe the simplest mode of cultivation, and the easiest to a beginner. Supposing, then, the lights to be 4 feet in width, and 5½ or 6 feet in length, we would recommend three plants to a light, each plant pretty well established in a separate pot previously. This will be better than sowing the seed where the plant is to grow; but however obtained, as soon as the plants are 3 or 4 inches or so in height nip the point out. Of the shoots that come from the axils of the leaves select two, as equal in strength as possible. Plant carefully, and train one of these shoots to the back and the other to the front of the frame, and do not stop them until they each are fully 2 feet long, but nip out the side shoots that come from the axils of the leaves as the shoots grow. When you do stop, leave three or four joints, which will be close together when you nip out the terminal bud. These joints will grow farther apart as the shoot lengthens; and from the axils of the leaves at the joints a shoot will come, which may be expected to show fruit, and should be stopped a joint above the fruit, and, if too much fruit set, you can thin out as you like. If this side shoot do not show fruit at the first joint wait until the second come; and if that do not, stop to cause the production of a fourth side shoot. Now, by this simple means you will have six main shoots from your three plants; the disbudding of these six shoots secures fine foliage without crowding with smaller shoots; and if from one main shoot you can manage to set and swell only one fruit, that will give you six fruit to the light, and so on in proportion to the number you would like, or the size of the Melon, bearing in mind that if a moderate number is taken the fruit will generally be better, heavier for its size, and richer in flavour. Remember, too, that whatever number of fruit you take from a plant, you must induce them to set, and begin to swell at once and together; for if only one fruit swell on a plant it is difficult to get any more to set and swell.

This is one of the reasons why we recommend the three plants to a light, and planted in the centre at regular distances, as it is easier to set two and four fruit on a plant at the same time than six or a dozen. The mode of disbudding the first side shoots and only leaving those at the point to come, secures strength of plant before the fruit shows, and renders much other pruning unnecessary. For many years we acted strictly on this simple plan, suggested by a careful study of the growth and nature of the plant, and with great general success. From press of other matters we have not been always able to see the plan simply carried out, but we have met with no other plan so good and so successful at a minimum of trouble and labour. Of course, when one plant is designed to occupy a large space, four, six, or more shoots must be obtained after the first stopping, and the more regular these shoots are in strength the more equally will the fruit be distributed and set. The three plants will be the simplest for the inexperienced. The simplicity will be a little increased if one plant have the two secondary shoots trained to the back, and the next plant have the two shoots trained to the front. Each plant will then be wholly in one position as respects light, temperature, &c., and the setting of different fruit at one time will be, if anything, easier.

We trust it will thus be seen that the primary shoot of the Melon is that which comes at once from the seed, the main stem as it may be called. The secondary shoots are those selected that come after the pinching-out the point of the main stem. These are what we recommend to train over the bed, disbudding the tertiary shoots that come from them nearest the stem; and the tertiary bearing shoots are those we allow to come from near the stopped point of these secondary shoots, and which tertiary shoots we stop again at the joint above the fruit.

ORNAMENTAL DEPARTMENT.

Some of the walks not pleasing us we ran the hoe over them when damp, and raked them level on a sunny day. The weather compelled us to mow, and was too wet to permit us to proceed with flower-bed planting; but if it continue fine, the most will be done before this is printed. Not wishing to repeat what has recently been said, we would refer to last week's notices for what is more important even than early planting. Looked after bulbs, Pinks, &c., and commenced propagating the latter.—R. F.

COVENT GARDEN MARKET.—June 12.

Under the influence of this sunny weather supplies are greatly improved both in quantity and quality, and a marked increase in Continental imports is observable; they now comprises Peaches, Nectarines, Melons, Figs, Apricots, and Cherries. Of home-grown Pines and Grapes there is an abundance, with a good sprinkling of Peaches and Nectarines, and a large quantity of open-air Strawberries. Potato trade dull at former prices, and unfortunately much disease is already making its appearance.

FRUIT.

TRADE CATALOGUE RECEIVED.

A. Barnaart, Vogelenzang, Haarlem, Holland.—*Catalogue of Dutch Flower Roots.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

Hospital (*A Young Gardener*).—There is a hospital specially devoted to diseases of the heart, at 67, Margaret Street, Cavendish Square. Without medical advice we know persons who have had heart-disease for twenty years, and are still alive. Physicians of greatest eminence merely advised temperate living and avoidance of violent exertion.

Seedling Cinerarias and Calceolarias (*R. D.*).—The flowers were punched flat and dry. Flowers, and indeed all specimens of plants, should be sent in damp moss in a box.

Fungus in Bark Bed of Stove (*Linda*).—The name of the fungus is Agaricus (Lepiota) clypeolarius, a British species, not uncommon in hothouses. It is not a recognised eatable species, and we cannot recommend any means for preventing its recurrence without injuring the tan; it will probably soon disappear of its own accord. You, or any one, would oblige us by sending three or four fresh specimens, in an old seidlitz-powder box (with a bit of wet moss), to Mr. W. G. Smith, 12, North Grove West, Mildmay Park, London, who is making a collection of drawings of Fungi.

Viola cornuta (*Brockfield*).—They are correct blooms as far as we can make out in their shrivelled state. Flowers should be enveloped by damp moss in a box for travelling.

Draining a Clayey Soil (*Sigma*).—We know the soil in your garden at Pengo, and recommend you to have drain pipes laid at 2½ feet from the surface, and the drains to be not more than 12 or 15 feet apart.

Wireworms in Vine Border (*Constant Reader, Glasgow*).—If your Vine border is so much infested with wireworms, we fear that nothing will do except removing the soil and fresh planting. Before resorting to this, however, stick pieces of Potatoes, Radishes, Carrots, Turnips, or any thing of that kind, all over the border, just deep enough to be out of sight, and go and examine them every morning, and do what you think best with the wireworms which you find. Make also holes where there are no roots, and put gas tar in the holes.

Thinning the Fruit of Orchard-house Peach and Nectarine Trees—Fruit Eaten by Woodlice (*Royal George*).—We would thin the fruit of your Royal George Peach tree to two dozen, and they will give you more satisfaction than six dozen. We have had more than three dozen from such a tree. We would thin at once. Timely thinning is the best means of preventing fruit dropping when stoning. To keep woodlice from going up the stems of your pot trees, tie a little clean wadding firmly round the stem, and over that wadding dipped in a mixture of oil and coal tar. Once we were greatly troubled with them on Cucumber plants in pots. They nipped the points of every young fruit. We had circular vessels made of tin or zinc, 1 inch wide and 1 inch deep, long enough either to go round the stem or round the inside rim of the pot when set firmly on the soil, and then the one-inch space was partly filled with tar and oil. The vessel must not be much less than an inch in width, or the woodlice will stretch over it.

Thrips on Vine Leaves (*E. D. S.*).—We found a few remains of thrips on the Vine leaves, and the remedy is tobacco-smoking and severe syringing afterwards. The leaves also had this peculiarity, that the leaflets seemed to come double, one over the other, and that, we presume, was the result of over-luxuriance, and a close, moist atmosphere.

Leaf Mould (*Andover*).—The leaves should be laid in a heap, not very thickly, and, being left until autumn, they will have decomposed sufficiently to be used for mixing with soil as compost for plants. If turned over now, and again in autumn, they will decompose more rapidly, and still more speedily if you mix a little loam with them at each turning. Leaves at the end of twelve months are usually sufficiently decomposed for potting-purposes, but they are not thoroughly so until the second year. For bedding plants the compost should consist of two-thirds loam and one-third leaf mould. Leaf mould is too open, and becomes too close and saturated, owing to the frequent waterings, to be employed alone.

Pampas Grass Killed by Frost (*Idem*).—The Pampas Grass with us is not killed, but is much injured. The old plants have suffered most. It is owing to the last exceptionally severe winter that so many are killed or injured, otherwise this beautiful Grass is sufficiently hardy to endure our ordinary winters.

Definition of Zonal and Nosegay Pelargoniums (*Idem*).—The name of Zonal was given a few years ago to that particular section of Pelargoniums to distinguish it from others. They were all called "Scarlet Geraniums," which did not truly express what was meant, as there are so many shades of colour in the flowers of that class, and it would be absolutely incorrect so to call Madame Vaucher, which has a pure white flower. Almost the whole of this family have a zone on the leaf, though sometimes faintly developed, hence the old-fashioned name of "Horseshoe" Geranium. The word "Zonal" at once conveys to the mind the particular section of Pelargoniums of which we may be speaking. A Nosegay Pelargonium is a Zonal in every sense of the word, the leaves are generally marked with a zone: and then a Nosegay differs only from other Zonals in the form of its flowers, the petals of which are narrow and long, and the three front petals wide apart from the two at back; the trusses are much larger than the usual size, and are more enduring under rain or hot weather. Nosegay Stella and the variety called Punch, or Tom Thumb, are respectively good examples of a Nosegay and the large-flowering Zonals.

Melon Plants Dying Off (*A. A. N. H.*).—The leaves sent have every appearance of suffering severely from mildew. Your only remedy is to syringe the plants and dust the leaves and stems on both sides with flowers of sulphur. The contact of the sulphur with the fungus, and the fumes that will be emitted whenever the sun shines powerfully upon the house will destroy the mildew; but if your plants are so much affected as it would appear from the leaves sent, we fear they are beyond cure, and that your best plan will be to replant. Melons like a strong unctuous loam if it contain grit, but we never found chalky soil or lime rubbish of any benefit in Melon culture.

Camellias Unhealthy (*Oxonian*).—We fear we cannot help you, for your plants appear to be in a very bad condition, and have been so for some time. We advise your shaking them out of the pots, removing all the soil, for that appears to us to contain something injurious to the roots, and potting them afresh. Use turf from a pasture where the soil is a good rather light or sandy loam, paring it off from 1 inch to 1½ inch thick, and tear it in pieces with the hand, and work it in among the roots. Pot rather firmly, afford good drainage, and do not bury the collar of the plant too deeply, in fact, it should be level with the rim of the pot. The plants after potting should be placed in a house with a moderate temperature, in a cool vinery for instance, and be moderately supplied with water, but always give enough to show itself at the drainage. They should have a good syringing every evening, and the atmosphere must be kept moist. Air should be given moderately, and if the plants are in a house where there are no Vines, slight shade should be afforded when the sun is powerful. We would not cut back the shoots, but if very close together we recommend thinning out the weak wood. All, or nearly all the flower-buds should be removed. If you treat your plants as above recommended they may recover, and in a year or two become healthy. Do not attempt to force them into second growth, but first secure a healthy root-action. You may continue the plants in a vinery until August.

Amaranthus melancholicus ruber Culture (*A Subscriber*).—The plant, of which you sent us a seedling in the rough leaf, is that named above, and should now have been 6 inches high and in the course of being planted out. The seedlings should be potted off singly in 60-sized pots, or three in a 48-pot, when in the condition of that sent us, and be continued in a frame with a gentle heat, such as that of a hotbed used for cuttings and seeds, shifting them into pots a size larger when those they were first potted in are filled with roots. Use a compost of rich turfy loam and leaf mould, with a free admixture of sand. The plants should be kept moist, and be slightly shaded after potting until established; but when they have recovered from the potting, air should be given freely. The seed should be sown at the end of March, or early in April, in a hotbed, and the plants potted off and grown on in heat until the beginning of June; they should be hardened off and planted out in the second week in the month.

Vine Leaf Scorched (*J. Banister*).—The discoloration of the leaf appears to be caused by its being scorched, probably through the sun shining powerfully on the glass whilst the leaves were wet; or it might be caused by water being poured upon a hot flue or pipe. A little air given early in the morning will prevent the first danger; in fact, the scorching of Vine leaves is chiefly attributable to not giving air before the sun acts powerfully upon the house. The brown or small black insects upon the leaves may be thrips, and there are traces of their having infested the leaf sent us. If you find them at work upon the leaves, keep the foliage of the Vines dry on a calm evening, and, shutting the house up close, fill it with tobacco smoke, and repeat the fumigation on the next night but one.

Bulbs after Flowering (*Auvergne*).—When the foliage begins to decay the roots should be taken up, and be placed thinly on a shelf in a cool airy shed to dry. When the stalks part freely from the bulbs they should be removed, and the bulbs stored thinly on shelves in dry sand. They will keep sound and plump until autumn, and then the loose scales and old roots may be removed.

Melons Diseased (*H. Buckmaster*).—The leaf sent is much rusted, and the evil will only disappear by syringing the plants overhead, and dusting the leaves on both sides with flowers of sulphur. This should be done early in the afternoon; the frame should then be shut up closely, and a mat be thrown over the glass if the sun is powerful. Do not practise the syringings with Gishurst, and tobacco fumigations are of no use. The cause of the evil is an unhealthy plant. The plants are very weak, and look as if they wanted air.

Rhododendrons Injured by Frost (*A Constant Reader*).—We would not cut off the shoots that were injured by the frosts of May, but leave them for a time, and in a week or two remove any of the dead parts, and these only.

Trees and Shrubs at an Elevation of 1000 Feet (*B.*).—If you were to state your locality, and the names of the shrubs (if any), or what is the vegetation of the locality, we might be able to advise.

Canada West (*Roland*).—The Pansy grows and flowers abundantly in Canada, and plenty of varieties may there be obtained. You might however, take over English-saved seed. We are not acquainted with any work on the climate of Upper Canada, but if you apply to the Commissioners of Emigration, 8, Park Street, Westminster, you will be furnished with reliable information as to the comparative advantages of different parts of the country.

Flowers for a Grave (*Margaret*).—We know Rhyl churchyard, and we think that if the grave was carpeted over with Stonecrop (Sedum acre), and studded with double purple Violets, they would thrive and be suitable.

Pelargoniums for Exhibition (*W. H. M.*).—*Zonals:* Clipper, Engénie Mézard, Monsieur Barré, and Madame Vaucher. *Variegated*, not being Tricolors: Queen of Queens, Alma, Golden Chain, and Golden Fleece. *Tricolors:* Mrs. Pollock, Sunset, Sophia Dumaresque, and Italia Unita.

Names of Plants (*H. W. E.*).—Cystopteris fragilis. (*W. W. B.*).—1, Lastrea dilatata; 2, Asplenium adiantum nigrum; 3, Lastrea sp.; 4, Asplenium trichomanes; 5, Lomaria spicant; 6, Lithospermum fruticosum. (*G. Brown*).—It is an impossibility to name seedlings. (*J. C.*).—Selaginella Martensii (1-2). (*B. Rose*)—1, Crataegus oxyacantha plena; 2, Saxifraga aizoon; 3, Helleborus viridis; 4, Vaccinium vitis-idæa; 5, (bad state); 6, Polemonium cæruleum. (*E. S. B. G.*).—1-2, Saxifraga cæspitosa, vars.; 3, Stellaria holostea. (*W. R.*).—Phlomis macrophylla.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 11th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GUARANTEEING HIGH-PRICED EGGS.

As there is considerable discussion about the quality of high-priced eggs just now, perhaps the experience of one of your subscribers may be useful. Of purchased eggs I have tried three sittings simultaneously: one Dark Brahma, one Black Spanish, one Black Duck of a foreign variety. The first sitting cost quite £1, for there was carriage to pay and a man's time in going to the station on three consecutive days, in addition to the high price for the eggs. The result was six chickens hatched, with which I was satisfied. The Spanish eggs I acquired by exchange from one who guaranteed the *bona fides* of one of your advertisers a short time ago. He stated that he was quite satisfied with his part of the agreement, made according to his own terms, and I in return asked him to guarantee me four chicks, and to be sure and send the eggs fresh. I received them on a Friday evening, and set them the following Tuesday morning; the result was only one chick saved out of three hatched. I wrote about it, and was promised, as all appeared fair and aboveboard, a few others, which I have never received. Of the Black Ducks, nine were hatched out of thirteen—a very good result; but they have never been advertised to my knowledge. I supplied five eggs of the Silver-spangled variety to a friend, and they were all hatched in nineteen days, or two days previous to the expected time; and as I had some Sebright eggs, which I offered for sale but did not part with, I set the layer herself on nine, and she hatched the whole of them, coming off with a strong brood on the morning of the twentieth day. I did not select the eggs, but took them in the order of their being laid.

All the three sittings which I purchased I set under first-class Dorkings exactly under the same circumstances, so there was no excuse in any way, the hens being well cared for and looked after. It is useless to talk of eggs being fresh when they do not hatch to time, for that is the great test. Of the three Spanish chicks, the first two were so weak that they did not survive the hatching, the third was so weak in the shell that to strengthen it I gave it raw egg, which helped it through.

These remarks, I am sure, will do good to all those who advertise eggs, if they will guarantee what they ask a high price for, and these continued disappointments are only prejudicial to their best interests. The Spanish eggs, I should state, cost with carriage expenses 16*s*.—Veritas.

GAPES IN CHICKENS.

The above disease seems in consequence of the cold wet weather, to be more than usually prevalent this year amongst Dorkings and other delicate breeds; and as I heard a short time ago of a remedy which appears to have been singularly successful, I have thought it might be of service to give it publicity.

It was furnished me by a friend who is breeding Dorkings this season from some of the best stock in England. His chickens having suffered severely from gapes, the following prescription was given to him as an unfailing cure, by a gamekeeper who has had the rearing of 1500 head of Pheasants per annum, and the very first results were so promising that I had thought of publishing them a fortnight ago, but have purposely delayed till they should be confirmed by subsequent experience. This, also, being satisfactory, I trust you may find room for the prescription, as follows:—Bol. Armen. 20 grs.; spirits of tar, 12 drops; cochineal, 1 oz. To be divided into pills the size of a peppercorn, and given on the first symptoms appearing, or one pill as a preventive to all chickens, where the disease has prevailed, about the sixth day after hatching. It may be as well to remark, that, as a preventive, the medicine must be used with caution, as it is a violent purgative.

I have not hitherto had much faith in internal remedies for this disease, but the following results have induced a change of opinion:—

1, A chick apparently dead from gapes, showing some slight signs of animation under warmth, was given a dose. Next morning it could stand, and was given another pill. It lived through the day, and my friend believes would have recovered, but having to leave in pursuit of his business avocations no further medicine beyond the second dose was given, and the chick died.

2, Another chick not so far gone, but very badly infected, recovered.

3, Whilst one or two chickens were lost daily previous to the trial of this medicine, none have died where it has been given.

I shall be glad if any of your readers who may try the above remedy will state their experience of its success. I make no claim to originality, I simply give the remedy as written for me by my friend referred to. It is new to me, and I publish it, but if any one else shall say that it is as old as Adam, I shall not deny it, only if it is effective let it be tried.

I will only add, for the sake of novices in poultry-keeping (old hands do not need it), that the best means of preventing any disposition to gapes are, to keep the chickens clean and dry, and to give them clear spring water, putting in the fountain each time it is filled a lump of camphor and sulphate of iron the size of a small pea. All chickens are much benefited by this in cold weather.—Nemo.

EXTENSIVE POULTRY-KEEPING.

In reply to your correspondent "Toby," I may remark that my experience as a poultry-keeper on a large scale is greatly at variance with his statements. I keep almost 2,000 fowls for eggs, and I have never been able to obtain much more than half the number of eggs per head which he does, and the quantity of food consumed is very much more.

As my fowls are nearly all common cross-bred birds, I should have attributed my ill-success to that cause if I had not carefully analysed "Toby's" estimate for 10,000 hens. He puts the cost of corn for that number at £2000. This sum would buy say 1335 quarters of barley or damaged wheat, weighing 50 lbs. per bushel, at 30*s*. per quarter, which is 5*s*. or 6*s*. below the present price, and the weight would be 238 tons 7 cwts. He allows £50 for flesh, which at £10 per ton gives 5 tons. This weight of food is to produce 2,000,000 eggs, which ought to weigh 2 ozs. each, or 111 tons 12 cwts.; thus, about 2 tons 3 cwts. of food is supposed to produce *one ton* of eggs. I leave your readers to judge whether it is probable Hamburghs or any other poultry will ever accomplish that feat. If it could be done, the profit at the present prices of eggs would be over 100 per cent.

A business of the kind proposed might, with a suitable soil and situation, and an energetic manager accustomed to the charge of large numbers of poultry, be carried on at a profit, otherwise it would be a decided failure.—George Chambers, *Standon, Herts.*

"STANDARD OF EXCELLENCE."

I am much surprised to observe it stated, that the "Standard of Excellence" is appended to a poultry book by permission of the Poultry Club. This to me looks very like disposing of the Club's "stock-in-trade," and for considerations, I, as a member of the Club, know not of.

The only return the members of the Club have received for a number of years' subscription has been the "Standard," and it now has apparently been handed over to others, who will thus receive the benefit of that which it has taken the Club years to produce. If the consideration for publishing the "Standard" is to be handed over in prizes at a Show, it will certainly be at a very distant date, as after the experience of Rochdale, notwithstanding the excuses made for that gigantic failure, few members will contribute to a certain prospect of a similar result.—Reform.

PREVENTING HENS SITTING.

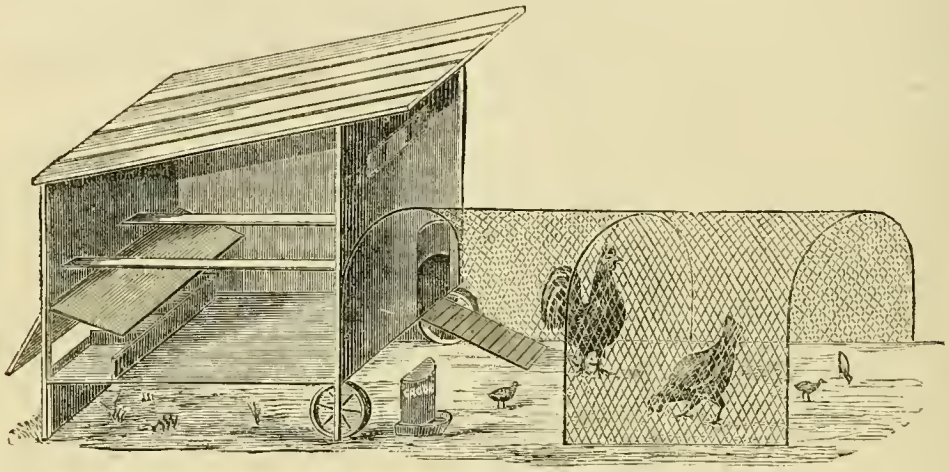
In your answer to "Kitty," you seem to think it a difficult task to prevent a Cochin hen sitting. I have found it so until this year, when I tried the plan recommended by the Hon. Mrs. Arbuthnot with great success.

It is as follows: Let the hen sit three or four days in the nest she chooses; then place her in a yard, or anywhere where there is no nest, and feed well; in four or five days she may be returned to her own yard, and in about a fortnight will lay again.—Philip Crowley.

The Prize Schedule of the Long Sutton and South Lincolnshire Poultry, Pigeon, and Rabbit Show manifests a very great advance on any of the three previous shows. In

each of the fifty-seven general classes prizes to the amount of £1 and 10s. will be awarded, old birds and chickens of each variety being appointed separate classes. Silver cups of the value of five guineas each will be given respectively for the best pen of Dorkings, Cochins, Brahmas, Spanish, Hamburghs, Game, Game Bantams, Bantams, and also for the best pen of Any other variety of fowls. In Pigeons, besides £1 and 10s. prizes for the respective classes, three five-guinea cups will be given for the best pen of Carriers, Tumblers, and the best pen of Any other variety of Pigeons. Besides those named there is a number of local prizes confined to residents only, and to these also, besides the money prizes, three five-guinea cups will be given. With so tempting and liberal a prize schedule there can be little doubt of a complete success being insured; and the Committee announce as the Arbitrators the well-known names of Messrs. Hewitt and Teebay. The Show will be held on October 9th and 10th, the entries closing on Saturday, September 28th, after which date no post entries will be received.

PORTABLE POULTRY-HOUSES.



While portable fowl-houses are occupying public attention, allow us to particularise one of those we advertise for sale. It is exceedingly portable, as light as possible consistent with durability, and very economical of space, besides possessing excellent interior arrangements for the comfort of the fowls for roosting, laying, &c. The nests are so arranged that any lady can collect the eggs without going inside the house. The open space under the house affords ample retreat for the inmates on wet days. The whole being mounted upon wheels, and provided with side fall-down lever handles, it can readily be moved about, and these houses represent one of the most useful improvements in poultry arrangements.

They are equally adapted to either garden or farming purposes, the land becoming enriched and cleared from insects at a small cost with benefit to both proprietor and fowls.—E. & F. Crook, 5, *Carnaby Street*.

INCUBATORS.

Your correspondent, "Brown Red," seeks for information relative to machines for hatching eggs, and suggests that you should undertake the task of testing the merits of rival incubators. Now, Messrs. Editors, I give you credit (and, indeed, editors generally), for having a vast amount of patience; but I think a trial of incubators would quite exhaust your stock of that virtue, as we are told it is, and a very great virtue it must be when exercised in relation to hatching eggs by the machines at present invented. To say which is the best incubator would be quite as difficult as to say which is the worst; they differ simply in detail; the principle in all is the same—viz., hot water—it matters little how the water is heated. Differ amongst themselves as they may about the merits or demerits or infringements of patents, the manufacturers of incubators have all the same end in view—to puff their individual machines and make money by them; they leave purchasers to find out the imperfections. The machines at present sold to hatch eggs are perfectly useless as practical and remunerative incubators. They may answer as an amusement, or as a hobby to waste time and money upon; for all else they are useless.

I have spent a considerable sum of money, and much time and patience in trials with incubators. I have tried warm water, boiling water, and steam; machines heated by gas, oil, spirits, and paraffin; machines where the water flowed and where it did not; and I have had made on principles of my own some that I thought would be sure to answer, but they simply turned out as good, or rather as bad as the others. I think, instead of testing incubators, if you would kindly open your columns to correspondents who have experimented with machines for the purpose of hatching eggs, something may be gained from an account of their failures if not their successes.

I would remark, that eggs in incubators appear to go on very well until about the fifteenth day. I have generally found that about this time the chickens died; numbers have I taken out of the shells perfectly formed and feathered, but dead. Now as to the cause of this I am quite in the dark:—Too much heat or not enough; well, I have hatched strong chicks side by side with those dead youngsters. Not enough ventilation—I do not believe in this much-talked-of ventilation in hatching eggs; I succeed best in hatching under hens when the hens are placed in a greenhouse in close boxes with only a small aperture for the hens to enter, and I am disappointed when I do not obtain twelve chicks from thirteen eggs; I frequently hatch the whole of the eggs. Much ventilation in natural or artificial hatching I have found not beneficial. Want of moisture—now I think we are in the neighbourhood of the mischief; to prevent dry heat in incubators, it is the practice to place water in the machines that moisture may be supplied by evaporation; if you then place a piece of glass in the incubator the surface of that glass will be found to be wet, or at any rate there will be moisture upon it: place another piece of glass under a sitting hen, it will be warm, but will present no appearance of moisture upon the surface. Take two eggs, the one from the machine, the other from under a hen; try both eggs with a thermometer, and they may be both of the same temperature, yet the feel in the hand is perceptibly different. Now, as to whether the contact with the flesh of the fowl has anything to do with this difference or not, I am not satisfied; at any rate, when I have time I intend to try a substance resembling to the touch the flesh of a sitting hen, and that substance is india-rubber. If a solid india-rubber bag, similar to those used by invalids when travelling (I do not mean stuff waterproofed with india-rubber), be filled with warm water, it will be to the touch exactly the same as the flesh of a sitting fowl; there is, in fact, a moist heat without perceptible moisture. I give the idea for others to work upon if they like.

I have already, I am afraid, made my letter too long, or I could add much relating to hatching eggs by artificial means.

We are not, I think, now as successful even with incubators as Réaumur and Bonnemain were in the last century, for it is stated that the machine made by the latter supplied the table of Louis XIV. with chickens. If I can render any information relative to incubators to any of your correspondents experimenting with machines, I shall be most happy to do so.—MERRYFIELDS.

BATH AND WEST OF ENGLAND SOCIETY'S POULTRY SHOW.

ALTHOUGH there were many persons who predicted that a second year's consecutive meeting of the Bath and West of England Society at Salisbury would prove a failure so far as the exhibition of poultry and Pigeons was concerned, we are much gratified to find that such unfavourable anticipations were by no means realised, for, on the contrary, it has very rarely, if ever occurred that so complete a success has been attained. Under the able and unceasing superintendence of Dr. Brent, of Exeter, and R. H. Bush, Esq., of Clifton, the acting management of the poultry department of this Society has become most popular, as an entry of over four hundred pens sufficiently attests.

It is well known among poultry-breeders that the present spring has been peculiarly unfavourable for the production of early chickens, the rapid changes of weather completely upsetting the calculations of the most careful and experienced, and even old birds have suffered very considerably from this cause also; yet, on the whole, the condition was better than could be anticipated. A single glance along the poultry tent proved that such vicissitudes had told most severely on the *Spanish* and Grey *Dorking* classes, want of general condition in them being the order of the day—in fact, it was in these two classes only that any considerable falling off occurred. The White Dorkings were, however, unusually good, though we could have wished to see a more extended entry. The Buff *Cochins* were of great merit, and the Partridge-coloured ones are worthy of especial mention. The *Brahmas*, with the exception of the winning pens, were not so good as we have met with on previous occasions, many of the pens being very negligently matched for exhibition. The *Game* classes contained many most excellent specimens, and the *Hamburghs* and *Polands* were capital. The Variety class was remarkably well filled, and some, especially trne-feathered Cuckoo-coloured Cochins, obtained much public notice. The Water fowls were excellent, and the representatives of both fancy and table birds in these classes were remarkably well shown. In *Bantams* this year's show was far in advance of previous ones, the Game Bantam class alone containing nineteen good pens.

Pigeons were numerous, and most of the classes such as left little room for improvement.

The weather was most favourable, and the poultry-tent, itself one of the best constructed we ever met with, was constantly one of the chief attractions of the showyard. To give greater opportunities of competition, a cock and *one* hen only were by rule shown this year (as most carefully laid down for the guidance of exhibitors), and it was, therefore, a matter of great regret to find that a very large number of excellent pens were thrown completely out of competition from non-attention to this regulation. The additional second hen thus shown, through the neglect of owners, caused many of the best pens certain defeat, as in all instances they were passed unnoticed. Exhibitors cannot be too careful in their attention to this particular before entering for competition, as regulations must be rigidly enforced. It was a matter of general congratulation that the health of the poultry shown was good without exception, and the great attention evinced in providing for the wants of the birds during their somewhat lengthy stay at Salisbury was all the most anxious owner could desire.

SPANISH.—First and Second, E. Jones, Clifton, Bristol. Third, R. Fulton, Deptford, Kent. Commended, Viscountess Holmesdale, Linton Park, Staplehurst, Kent.

DORKINGS (Coloured).—First, Viscountess Holmesdale. Second, L. Patton, Taunton, Somerset. Third. Dr. Hewson, Coton Hill, Stafford, Staffordshire, Commended, C. Cork, New Shoreham, Sussex.

DORKINGS (White).—First and Second, H. Lingwood, Barking, Needham Market, Suffolk.

COCHIN-CHINA (Cinnamon and Buff).—First, G. Shrimpton, Leighton Buszard, Beds (Buff). Second, J. H. Dawes, Birmingham. Highly Commended, Mrs Llewellyn, Court Colman, Bridgend, Glamorganshire; W. Bayliss, Walsall, Staffordshire (Buff). Commended, F. W. Rust, Hastings, Sussex (Buff.)

COCHIN-CHINA (Brown and Partridge-feathered).—First and Second, J. Stephens, Walsall, Staffordshire (Partridge). Commended, J. K. Fowler, Prebendal Farm, Aylesbury, Bucks (Partridge.)

COCHIN-CHINA (White).—First, F. W. Zurhorst, Dublin. Second, H. Hobson, Walsall, Staffordshire.

BRAHMA-POOTRA (Dark).—First, R. W. Boyle, Bray, Wicklow, Ireland. Second, J. K. Fowler. Highly Commended, Lieut.-Col. Lane, Lily Hill, Bracknell, Berkshire. Commended, Col. Stuart Wortley, Grove End Road, London; Lieut.-Col. Lane.

BRAHMA-POOTRA (Light).—First, F. Crook, Forest Hill, Kent. Second, H. Dowsett, Pleshey, near Chelmsford. Highly Commended, F. Crook. Commended, J. Pares, Postford, Guildford, Surrey.

GAME (White and Piles).—First, Rev. G. S. Cruwys, Tiverton, Devon (Piles). Second, S. Matthew, Stowmarket, Suffolk. Commended, Rev. F. Watson, Kelvedon, Essex.

GAME (Blacks and Brassy-winged, except Greys).—First, Rev. G. S. Cruwys (Black). Second, J. Pares (Black). Commended, A. D. Edwards, Huddersfield, Yorkshire (Black); C. Bulpin, Bridgewater, Somerset.

GAME (Black-breasted and other Reds).—First, S. Matthew. Second Rev. F. Watson. Highly Commended, H. Loe, Appledurcome, Godshill, Isle of Wight. Commended, T. L. Mills, Orcheston St. Mary, near Devizes Wilts; Rev. G. S. Cruwys.

GAME (Duckwings and other Greys and Blues).—First, S. Matthew. Second, T. Dyson, Halifax, Yorkshire. Commended, Rev. G. S. Cruwys.

HAMBURGHS (Golden-pencilled).—First and Second, F. Pittis, jun., Newport, Isle of Wight. Highly Commended, S. Onley, Cheltenham.

HAMBURGHS (Silver-pencilled).—First, H. Pickles, Earby, Skipton, Yorkshire. Second, H. Beldon, Goitstock, Bingley, Yorkshire.

HAMBURGHS (Golden-spangled).—First, I. Davies, Harborne, near Birmingham. Second, Messrs. S. & R. Ashton, Mottram, Cheshire. Highly Commended, W. A. Hyde, Hurst, Ashton-under-Lyne, Lancashire. Commended, N. Marlor, Denton, near Manchester.

HAMBURGHS (Silver-spangled).—First, H. Beldon. Second, A. K. Wood, Castle Donington, near Derby. Highly Commended, Mrs. Pettat, Ashe Rectory, Overton, Hampshire.

POLISH (Black, with White Crests).—Prize, H. Beldon.

POLISH (Golden).—First, H. Beldon. Second and Commended, Mrs. Pettat.

POLISH (Silver).—First, H. Beldon. Second and Commended, G. C. Adkins, The Lightwoods, near Birmingham.

MALAY.—Prize, J. Hinton.

ANY OTHER DISTINCT VARIETY.—First, Col. Stuart Wortley (French). Second, Rev. D. B. Binney, Shirley, Southampton (Crêve Cœur). Equal Second, J. C. Phair, Southsea, Hants (Cuckoo Cochins). Equal Third, S. A. Wyllie, East Moulsey (Houdan and La Flèche). Equal Third, Miss S. H. Northcote, Upton Pynes, near Exeter (White Spanish). Highly Commended, Col. Stuart Wortley (French); J. C. Phair (French); J. K. Fowler (Crêve Cœur). Commended, J. Pinckney, Great Durnford, Salisbury (Crêve Cœur); J. H. Amory, Bolham, Tiverton (Sultan); J. C. Cooper, Cooper Hill, Co. Limerick (Crêve Cœur and Sultan); J. W. Harrison, Spalding (Cuckoo Cochin); Miss S. H. Northcote (Black Minorcas).

GUINEA FOWL.—First, Miss S. Northcote. Second, T. C. Harrison.

DUCKS (White Aylesbury).—First and Second, J. K. Fowler. Highly Commended, Mrs. L. M. Squarey, Oldstock, Salisbury. Commended, H. Dowsett.

DUCKS (Rouen).—First and Second, G. N. Hulbert, Perrott's Brook, Cirencester. Highly Commended, J. W. Harrison; H. Dowsett. Commended, C. Edwards, Wrington, Somerset.

DUCKS (Any other variety).—First and Second, T. C. Harrison. Extra Third, W. Pinckney (Muscovy). Commended, J. H. Amory (White Musk); W. C. Finch, Salisbury (Peruvian Musk).

GEESE.—First, J. K. Fowler. Second, L. Patton, Comeyt rowe House, near Taunton. Highly Commended, J. C. Cooper; L. Patton.

TURKEYS.—First, J. C. Cooper. Second, Capt. Warren, Basingstoke.

BANTAMS (Gold or Silver-laced).—First, Mrs. Pettat (Silver-laced). Second, Messrs. S. & R. Ashton, Mottram, Cheshire.

BANTAMS (White or Black).—First, N. Marlor, Denton, near Manchester. Second, J. R. Jessop (White). Highly Commended, Miss K. Charlton, Chapelthorpe, near Wakefield (Black). Commended, Mrs. F. H. Freke, Highworth, Wilts (Black, and Clean-legged Black); Messrs. S. and R. Ashton (Black); Rev. P. W. Story, Daventry, Northamptonshire (White Feathered-legged).

BANTAMS (Game).—First, A. I. Robson, Sunderland, Durham (Black Red). Second, F. Pittis, jun. Extra Third, T. Dyson, Halifax, Yorkshire. Commended, T. H. Wyndham, Salisbury, Wilts; S. Lang, jun., Burrow, near Bristol, Somersetshire (Black Red); J. K. Fowler (Black-breasted Red); E. Sheerman, Chelmsford, Essex.

SINGLE COCKS.

SPANISH.—First, withheld. Second, J. Langdon, Sherborne, Dorset.

DORKING.—First, J. W. Harrison. Second, H. Dowsett. Highly Commended, Viscountess Holmesdale.

COCHIN-CHINA.—First, H. Mappleheck, Wondfield, Moseley, Birmingham (Buff). Second, J. H. Dawes, Moseley Hall, Birmingham (Buff). Highly Commended, S. Onley, Cheltenham (White); R. Barrett, Stroud, Gloucestershire (Buff); J. Cattell, Birmingham (Buff). Commended, E. Pigeon, Lympstone, near Exeter (Partridge Cochin); J. K. Fowler (Partridge).

BRAHMA POOTRA.—First, R. W. Boyle, Bray, Co. Wicklow (Dark). Second, G. Meares, Thornhill, Bittern, near Southampton (Light). Commended, J. K. Fowler.

GAME.—First, Rev. A. G. Brooke, Ruyton XI. Towns, Salop (Black-breasted Reds). Second, S. Matthew. Highly Commended, S. Dupe, Evercreech, Bath; Rev. G. S. Cruwys.

ANY OTHER DISTINCT VARIETY.—First, J. Hinton (Silver Polands). Second, J. Pinckney (Crêve Cœur). Highly Commended, F. Pittis, jun. (Golden-pencilled Hamburgh).

PIGEONS.

CARRIERS (Blue or Silver).—First, R. Fulton, Deptford, Kent (Blue); Second, J. C. Ord, Pimlico, London (Blue). Commended, J. C. Ord (Silver).

CARRIERS (Any Colour except Blue or Silver).—First and Second, R. Fulton. Extra Second, J. W. Harrison, Spalding, Lincolnshire (Dun).

TUMBLERS (Almond).—First, R. Fulton. Second, J. Ford, Monkwell Street, London. Highly Commended, J. Ford; J. E. Breward, Coventry. Commended, R. Fulton; H. Yardley, Birmingham.

TUMBLERS (Any other variety).—First, R. Fulton (Short-faced). Second, H. Yardley. Commended, R. Fulton; F. Mills, Orcheston St. Mary, Wilts (Bald-pate).

POUTERS.—First and Second, R. Fulton. Highly Commended, R. Fulton; J. Gould, jun., Taunton, Somerset; J. E. Breward, Coventry.

RUNTS.—Prize, H. Yardley.

JACOBINS.—First, C. Bulpin. Second, Rev. F. Watson.

FANTAILS.—First, S. A. Wyllie, East Moulsey, Surrey. Second, H. Yardley. Highly Commended, H. Yardley. Commended, Miss J. Milward, Newton St. Loe, Bath.

OWLS.—First, S. A. Wyllie. Second, C. Bulpin.

TRUMPETERS.—First and Second, C. Bulpin.

BARBS.—First, R. Fulton. Second, S. Dupe, Evercreech, Bath, Somerset.

TURBITS.—First, Rev. F. Watson. Second, C. Bulpin. Highly Commended, H. Yardley.

NUNS.—First and Second, C. Bulpin.

DRAGONS.—First, H. Yardley. Second and Highly Commended, E. Pigeon, Lympstone, near Exeter.

ARCHANGELS.—First, C. Bulpin. Second, H. Yardley.

Any other New or Distinct Variety.—First, H. Yardley. Second, Extra Second, and Highly Commended, F. Broemel (Ural Ice Pigeons, Fairy Swallows, Swiss). Commended, H. Yardley; H. Snushall, Gedney, Lincolnshire (Spangled German Ice Pigeons.)

The Arbitrators were Edward Hewitt, Esq., of Sparkbrook, Birmingham; and W. B. Tegetmeier, Esq., of Muswell Hill, London.

ALBION SOCIETY'S SHOW OF PIGEONS AND FANCY RABBITS.

The first Show of this Society, held in the Dining Halls, Cambridge Street, Birmingham, commenced on the 11th inst., and will continue till the 14th.

PIGEONS.

Carriers.—*Cocks.*—First, H. Yardley, Market Hall, Birmingham. Second, F. F. Foster, Navigation Street, Birmingham. *Hens.*—First, F. F. Foster. Second, H. Yardley.

Pouters.—First, F. F. Foster. Second, H. Yardley.

Balds and Beards.—First, H. Yardley. Second, F. Waitt, Birmingham. Commended, F. F. Foster.

Tumblers.—*Almond.*—First, F. F. Foster. Second, E. D. Careless, Birmingham. Highly Commended, H. Yardley. *Short-faced.*—First, F. F. Foster. Second, H. Yardley. Highly Commended, E. D. Careless. *Other than Short faced.*—First and Commended, F. F. Foster. Second, J. W. Edge, Aston New Town. *Muffed.*—First and Second, E. D. Careless.

Runts.—First and Second, H. Yardley.

Jacobins.—First, H. Yardley. Second, J. W. Edge. Commended, F. F. Foster.

Fantails.—First, H. Yardley. Second, J. W. Edge. Commended, H. Yardley; F. Waitt.

Trumpeters.—First, H. Yardley. Second, F. F. Foster.

Owls.—First, H. Yardley. Second, J. W. Edge.

Nuns.—First and Commended, J. W. Edge. Second, H. Yardley.

Turbits.—First, H. Yardley. Second, J. W. Edge.

Barbs.—First, F. F. Foster. Second, H. Yardley. Commended, J. W. Edge.

Archangels.—First and Second, H. Yardley.

Swallows.—Prize, J. W. Edge.

Magpies.—First, J. W. Edge. Second, F. Waitt, Birmingham. Commended, H. Yardley; F. F. Foster.

Dragons.—First, J. W. Edge. Second, H. Yardley. Highly Commended, J. W. Edge.

Antwerps.—First and Second, H. Yardley. Commended, J. W. Edge.

Any other New or Distinct Variety.—First and Third, H. Yardley (Blue and Black Fairies, Swiss, and Ural Ice). Second, F. Waitt (Ural Ice and Black Fairies). Fourth and Fifth, F. F. Foster (Red Fairies and Swiss). (An excellent class. The whole class highly Commended.)

RABBITS.

For Length of Ears (Grey and White).—*Buck.*—First, B. Johnson, Birmingham. Length of ears, 22½ inches; width, 5¼ inches. Second (Yellow and White), B. Johnson, Length, 22 inches: width, 5¼ inches.

Black and White (For all properties).—*Buck.*—First, H. Beech, Birmingham. Length of ears, 20¼ inches; width, 5 inches. *Doe.*—Second, W. H. Webb, Deepfields, near Bilston. Length, 19⅞ inches; width, 5 ins.

Yellow and White (For all properties).—*Doe.*—First, H. Attwood, Birmingham. Length of ears, 19⅞ inches; width, 5 inches. *Buck.*—Second, B. Johnson. Length, 20¼ inches; width, 5¼ inches.

Tortoiseshell (For all properties).—*Doe.*—First, W. Worrall, Smethwick. Length of ears, 20¼ inches; width, 5 inches. Second, H. Attwood. Length, 19½ inches; width, 5 inches.

Grey and White (For all properties).—*Buck.*—First, W. H. Webb. Length of ears, 19¾ inches; width, 5 inches. *Doe.*—Second, H. Attwood. Length, 19¾ inches; width, 4⅞ inches.

Self Colour.—*Grey Buck.*—First for colour and Second for weight, H. Attwood. Length of ears, 21 inches; width, 5⅜ inches. Weight, 8 lbs. 10 ozs. Second for colour and First for weight, B. Johnson. Length, 20⅜ inches; width, 5 inches. Weight, 11 lbs.

Judges.—Mr. S. Coleman, Mr. B. Guest, Mr. C. Hall, and Mr. J. Newton.

GAME FOWLS.

I think that "Yorkshire" advocates breeding rather too closely in his last article (page 286), and if it could be avoided, I should object to breeding any nearer than with a "first-cousin" strain in breeding in-and-in. With all due deference to the opinion of "Yorkshire," in which he is not singular, I still adhere to the "well-up," well-sickled, and spreading or fanned tails, which should be narrow only at the base of the tail. I do not, of course, like a broomy tail, as being too thickly feathered, but think that the switch tails present the shape of a broom more than the spread tails.

In hens of the same strain, I prefer the spurred ones, as harder and throwing more cock chickens. They are also, I think, deeper or higher bred as a rule, and cock-fighters prefer them, if of first-rate shape, to other hens. Of the two hens which "Yorkshire" instances, the Black was probably of the slower strain, as Blacks are generally slower than the Spangled, and the latter are quicker, and shorter in body generally. I have never seen spurred Black hens, and I think pure-bred Blacks are too slow for the pit, though the Brassy-winged Black cocks are quite equal in general to the best willow-legged Black-breasted Red cocks.

As to the weights in the mains of the present day, the average is, perhaps, 5¼ lbs. and varies from 4½ lbs. up to 9 lbs.

I have a few notes on the Duke of Leeds' "Shackbags" of one hundred years ago, and others relating to Colonel Mordaunt, afterwards, I think, Sir John Mordaunt, Bart. Could "Yorkshire" state what colour the "Shackbags" were of?

I have heard of the Muscovite Black and Brown Game fowls as being of the Muffled variety of Game fowls. I have also heard of Mr. R. M. T. Scrimminger as a breeder living near Lutterworth, in South Leicestershire, and breeding the two Red varieties. I think he took a silver cup at Birmingham for Brown Reds, and a first prize for Black-breasted Reds at the same time—in 1865. He is a cocker, I hear.

All the breeders I mentioned are breeders and not buyers of Game fowls, but Mr. Gamon has since sold off his whole stock; so has Sir St. George Gore, I am sorry to see. I think that Mr. Brierley's Black-breasted Reds are, perhaps, the very best and handsomest birds as to colour ever exhibited. They have the true red eye, are of a most brilliant red colour, of good shape, and spirited carriage, and are evidently of very good blood. I see they took both first prizes for Black-breasted Reds at the last Accrington Exhibition, which shows that Messrs. Teebay and Tegetmeier judged that class very correctly. I admire Mr. Statter's Brown Reds for their short bodies, good shape, and spirited carriage, and for their dark brown, not black hens, of the true Brown Red colour, and for the red-brown breasts in the cocks. I do not think Mr. Brierley's Brown Reds so good as many other strains, though they are good. Mr. Brierley should not mix his splendid strain of Black-breasted Reds with Brown Reds, or any other colour, or he will certainly spoil them, and brown their colour, spoil the red eye and bright plumage, and mar all their best characteristics.

As to Piles, I think the best ever exhibited were shown at the Birmingham Exhibition ten or twelve years ago, by a Mr. Richard Dummeller, of Shackerstone Heath, near Atherstone, Warwickshire. These birds took several first prizes at Birmingham, and were evidently of very high blood; they had red eyes and white legs. Mr. Brierley's Black-breasted Reds would make splendid Piles, putting a red-eyed Pile cock to the hens. As to red-eyed willow-legged Duckwings, I think a Mr. Henry Shield, of Preston, near Uppingham, Rutlandshire, bred the best I ever saw; they were very short in body and were very quick. He had also some capital White Game—red eyes, white legs—and the best Ginger Brown Reds, with willow legs, I ever saw. He bred all colours, including Blues and the Ginger Blues. He has now moved to near Northampton, I hear.

Could "Yorkshire" say which was the old favourite colour for the pit in Yorkshire prior to the introduction of the Brown Reds? which sort, I think the Yorkshire breeders had chiefly from Lancashire, a county which has rather better birds than Yorkshire in general; also, what other breeds the late Earl of Mexborough had besides the Ginger-backed Yellow Duckwings? I think Bradford and its vicinity has about the best birds in Yorkshire. Staffordshire and Cheshire have some capital birds, I know. I think Lancashire stands first.—Newmarket.

INCREASE OF PRIZES FOR RABBITS.

In reply to the suggestions of Mr. John Taylor, Sheffield, in your last issue, permit me to inform him and other Rabbit fanciers, that the Committee of the Wolverhampton Poultry Show have resolved to add Rabbits to their prize list this year, and had, some days before the publication of Mr. Taylor's letter, decided upon the very amounts he wishes as prizes—viz., first prize, £1; second, 10*s.*; the entrance-fee to be also as he suggests, 2*s.* Our schedule is preparing, and particulars will appear in your advertising columns shortly.—Thomas J. Barnett, *Secretary.*

LIGURIAN DISAPPOINTMENTS.

Mr. T. Addey, sen., has sent us a long letter, in which he states that he was employed in Messrs. Neighbour's apiary for fourteen weeks during the last summer, and that he did not find that their bees had foul brood. We regret to say, however, that we have now before us the most conclusive evidence that "J. B.'s" is not the only instance in which Messrs. Neighbour have sent out infected stocks. Mr. Addey also states that Mr. Carr has presented him with a drone-breeding queen, and recites two instances in which his bees have done well. This does not, however, disprove the fact that the stock sent to "J. B." proved a complete failure, and that Mr. Carr not only withheld all compensation, but has left his letters unanswered.

BEES AND BEE-KEEPING IN EGYPT.

It may be remembered that in No. 278 of "our Journal," when commencing a series of articles upon "The Egyptian Bee," I stated that the distinguished German apiarian Herr Vogel had taken charge of the illustrious little strangers, whose involuntary migration into Europe had been made under the auspices of the Berlin Acclimatisation Society. After succeeding to admiration in multiplying and disseminating his interesting *protégées*, Herr Vogel seems to have been inspired with the desire of making the acquaintance of *Apis fasciata* in its own habitat. This desire he was enabled to gratify during the spring of 1866, and, I have now much pleasure in submitting to the readers of "our Journal" a translation of the very interesting account which he has given of his apiarian observation during his Egyptian trip.—A Devonshire Bee-keeper.

THE EGYPTIAN BEE.

The recluse who never moves outside the four walls of his house, or at the farthest goes not beyond the familiar shade of the trees in his own garden, may well believe that the sun shines not on foreign lands, and that the inhabitants of distant countries must perforce dwell in utter darkness; but the bee-master should at least know from what field and from what flower his bees gather sweet nectar and gaily-tinted pollen, as well as the places from which they fetch water. The reader of our bee Journal may also if he pleases travel in thought through Germany, Italy, Poland, Russia, and by land to all the countries of Europe—by water to America, Asia, and Africa; to the lands of the Mohammedan and the heathen, and witness how the little bee is everywhere provided for by the beneficent Creator, and how she is fostered by man.

Let me beg the courteous reader to permit himself to be in thought transported with me through the air and over the blue waters of the Mediterranean to the ancient city of Cairo. But Cairo alone, the unsubdued or rather the invincible, is not, with all her glory and magnificence, sufficient to captivate us, for we are anxious to see the little bee and the Egyptian bee-masters. Hiring donkeys, the driver straightway conducts us to Old Cairo, and to the Arab Soliman, who is gravedigger in the English churchyard. Here accordingly we find the old Arab occupied in the God's-acre under the shade of the tall trees; but he is not now making a last resting-place in the cool ground for any child of man, but is only closing a bee-hive, into which he has just shaken a swarm of his wards. Our dragoman introduces us as European bee-keepers who are come to sit at the feet of the Egyptian bee-master, and listen to the teachings of Egyptian wisdom. Alas, it is not permitted to us to read in the eyes of the Arabian bee-master the impression which this representation has made upon him. Soliman certainly wears no yash-mak, like the feminine beauties or ugly ones of his land, but has simply a bee-cap drawn over his head. We express to him our surprise at seeing in Old Cairo a bee-cap exactly similar to those we have met with in Europe, when Soliman at once becomes communicative, and relates as follows:—"In the year 1242* the foreigner Hammerschmidt bought of me a stock of bees, which he took to Europe. In the following year Hammerschmidt came again from Berlin, a town of the unbelievers in the cold north, to Cairo, and brought me this cap as a present. The inventor of the bee-cap is Vogel, a bee-keeper in Europe who received my bees. Neither my father, nor my grandfather, nor great-grandfather knew bee-caps, and formerly I also continually went amongst my bees without a bee-cap. How proud, then, am I to possess the first bee-cap in the land! How costly is the material of this fabric! The great Prophet himself could not have worn worthier or better raiment! The colours of the material and of this band, are they not excellent and ravishing to the eye as a rose that is kissed by the first blush of the dawn? Vogel's friend has washed this fabric with pearls of dew in the morning, and dried it in the evening glow of the heavens!"

We miss hearing the farther praises of the bee-cap whilst making the following note in our diary:—

1. "In the year 1865, the Berlin Acclimatisation Society sent through the photographer Hammerschmidt a bee-cap, which Vogel had furnished, to the Arab Soliman, in Old Cairo. This cap is the first in Egypt."

We are pleased at the truthfulness of the Arab, who does not extol himself as the inventor of the bee-cap, whilst we pardon his mistake † in ascribing the invention to Vogel.

In order not to weary the reader with the diffuse and pompous speeches of the old Arab, we merely extract the farther notices from our diary, permitting ourselves only to add some explanatory remarks.

2. "The ruler of the bees is slender as a palm tree, the male heavy as a crocodile; the slaves are most like the mother, must work day and night, cleave in love and service to the ruler, and slaughter the males at command. The ruler orders the murder of the males as soon as the flowers are withered in the heat of summer; the males are unable to defend themselves in that they are stingless. If the males were to remain alive in the summer they would obtain authority; but in the bee-community only the mother shall rule."

The Arab also knows three different kinds of bees—the queen, drones, and workers. He says that the worker-bees may be so attached to the queen because they owe their existence to her. The egg of the bee is not unknown to the Arab bee-master; he knows that out of it will come a worm, and in time a young bee.

3. "Bees swarm in Old Cairo in the month of March, when the clover begins to flower. At this time the Arab daily lays his ear on his stocks in order to hear when the old mother-bee begins to 'weep'. When this 'weeping' is heard he counts upon a swarm being pleased to issue the next day. As the queen will then forsake her children and her government to found a new empire, the Arab deems the sounds of lamentation very natural."

We can scarcely understand this mistake in respect of swarms. Soliman firmly maintains that swarms can be looked for only when the rulers "weep" (pipe or clack). From what we heard, we concluded that the Arab first watches for swarms when a stock has already sent off a prime swarm, and when the young queens in the stock hives pipe and clack. The first prime swarms must therefore certainly fly off, unless he should by accident discover them hanging on a tree. To the question, Whether he did not sometimes have a swarm without the queens having "wept," he answered that then he had either missed hearing the "weeping," or the swarm found was a wild (flown away) one.

4. "The swarms are shaken into empty cylinders. In order that the bees may be pleased with their new dwelling, empty and full honeycombs are set up in it. This can be easily done, as all cylinder-hives are of equal width. Each comb must be placed on a forked stick, and by means of this may be firmly fixed, if the length of the stick be the same as the diameter of the hive."

It is certain that during the past hundred years the Egyptians have been able to prevent swarming. Soliman is, in this point of his practice, perfectly Dzierzonian, without, however, knowing Dzierzon's name. That the Arab prevents swarming in order to dry the tears of the ruler of the swarm, is, practically, of no importance whatever.

5. "If a stock swarms, notwithstanding that the queen has not yet 'wept,' the Arab makes an artificial swarm. When the bees have taken flight, he, towards evening, stops the entrance in the front disc of the cylinder, opens the door behind, takes out a portion of the comb with the bees hanging on it, and places it carefully in an empty cylinder. In order not to weaken one stock too much, he takes combs and bees from two or three hives, and forms his artificial swarm by putting them all together. When the back door is again closed the front entrance is opened, so as to receive into the parent stock, instead of into the artificial swarm, those bees which have collected during the removal of the combs. The Arab thinks that he has then a queen in the new stock, and that otherwise the operation fails. 'When,' says Soliman, 'I do not divide and remove the bees at the right time, the young bees kill their old mother and cast her dead body out of the hive.'"

Our friend Soliman also understands dividing and transporting. He only divides those stocks that have young queens which pipe and clack. He always takes care that he has a young queen in the artificial swarm, because after a queen has been hatched the divided swarm would not have suitable brood for raising a queen, as when a stock pipes and clacks after the first swarm has issued all the brood is already sealed over. That artificial swarms may be made with brood only, passes the comprehension of the Arab, and thinking is not his *métier*. I doubt not that to this day there are old boys in Germany that know no more of the manner in which a queen is produced than Soliman himself. Some years since a bee-keeper died in this neighbourhood, who never could thoroughly comprehend that it was possible for the bees to raise a queen out of an

* Hegira. † *Errare humanum est.*

ordinary worker-egg or larva. In order to demonstrate the matter to him *ad instantium* and *ad oculos*, I made on my own stand, and before his eyes, an artificial swarm by means of brood-comb. Every comb did he most rigidly examine, and finally declared it certain that no royal cells were there. Eight days afterwards I took this opposer of the march of intellect to the artificial swarm, lifted out the combs, and showed him five adhering royal cells. "Yes," he admitted, "those are queen cells." I detained the old man in order to convince him, and described the manner in which a queen-bee was reared. During my discourse he shook his head, as I fondly thought, in wonder at the marvellous instinct of the bee; but some days afterwards I heard that this incredulous and mistrustful blockhead had thus expressed himself:—"Why, this blunderer would make me believe something. He puts royal cells into the hive behind my back, and would then persuade me that the queenless bees had built them." *Roma locuta, res finita,* thought I. Our bee-colleague Soliman could, indeed, hardly have expressed himself worse.—W. Vogel.

(To be continued.)

ARTIFICIAL SWARMS.

Until I received a hive of Ligurians from Mr. Woodbury last year I had not adopted frame-bar hives; I then had some made. They were painted of a brilliant red colour, and with these I attempted to make artificial swarms of Ligurians, by taking a comb of Ligurian brood, putting it into one of these frame-bar hives, and placing the latter in the room of a strong stock of black bees when a large number of them were out foraging. The stocks of black bees used for the purpose were in straw hives, Stewarton octagons, painted red, &c. The result in every case was the same. The black bees on seeing the frames refused to enter the frame-bar hives; honey dropped within the entrance failed to overcome their repugnance, and after waiting undecided for a time, they at length crowded round the entrance to the nearest stock hive, to which they slowly advanced, fanning with their wings, and in other ways intimating to the occupants their peaceful intentions and desire to be admitted into fellowship. I nearly closed the entrance to the stock hive, the better to enable the inmates to offer resistance; but this they did not appear disposed to do, for many of the applicants for admission were heavily laden with pollen, and, doubtless, with honey. I then closed the entrance, swept away the besiegers, and covered the hive with a cloth. The strangers then went under the stool, and found their way thus under the cloth to the closed entrance of the hive. I took away the cloth, removed the obstruction from the mouth of the hive, and the entire mob of strangers rushed in. There was no instance of fighting—indeed, I think the occupants were delighted to see their visitors laden with presents, each bearing a contribution to the wealth of the community. However, on the following day there was a commotion in some of these hives (not in all), the bees rushing out and up the front and there clustering; possibly there may have been some instances of queen encasement; but the disturbance subsided in the course of the day, and the affairs of the hive went on smoothly.

Now, in many of these cases the bees which refused to enter the untenanted frame-bar hive containing Ligurian brood comb, nevertheless did subsequently enter a neighbouring stock hive totally different in appearance from their own; the bees of a common straw hive freely entering a Stewarton octagon painted red, and *vice versâ*: so the empty frame in the frame-bar hive appears to have been the objection.

In order to utilise the black bees in raising Ligurian queens in this way I raised the stocks of black bees intended to be used on frame hives, of course taking away the crown-board, and filling in the open corners of the frame hive with triangular pieces of wood, and making all tight and close with brown paper and paste. The black bees thus soon became accustomed to the frames, and I had no further difficulty in using them for the purpose named.—M. S.

[The persistent refusal of your black bees to enter the strange domicile to which you invited them, was doubtless owing to the Italian brood comb being denuded of bees. Whenever an artificial swarm is made by removal in the manner above described, all the bees that adhere to the brood comb should be suffered to remain on it, making sure, however, that the queen is not among them by previously ascertaining her presence on another comb. The wanderers who find themselves so suddenly rendered homeless will then more readily enter their new habitation, and no serious quarrel need be feared. Another advantage is, that the young bees adhering to the comb furnish the embryo colony with the class of "nurses" described by Huber, which are much more likely to succeed in raising queens than a chance-medley collection of foragers, which may from age have become either wholly or partially disqualified for the task. If other stocks are in close proximity, it is well also to prepare for the operation by shutting them up overnight, and removing them out of the way of the wanderers until they have entered and accepted their new domicile.]

OUR LETTER BOX.

Basingstoke Poultry Show.—Mr. C. Cork took the second prize for Dorkings at this Show.

Brahmas at Launceston Show.—The first prize was awarded to T. Richards, Devon Great Consols, Tavistock,

Poultry Farm for Eggs.—If "*Er*" will enclose to our office a letter in a stamped envelope, we will direct it to "Toby."

Game Cock (*R. C.*).—We are not surprised at the bird's deficiency in courage, for the inhabitants of the yard from which you purchased him were bred for exhibition, not for the cock-pit.

Remedy for Gapes (*W. T.*).—According to your list of failures, you have unsuccessfully tried every known remedy for the gapes. We have never known camphor fail. We have not had a case of gapes this year, last year we cured hundreds with camphor pills and camphor julep. We have used a decoction of wormwood in all our chickens' water this year, and we believe it has acted as a preventive. Our theory has always been, that these parasitical worms came from larvæ that are peculiar to rain water. The worms are identical, or almost so, with the myriads that are to be seen at the bottom of a water-butt which catches rain-water. If these are brought in contact with camphor they die at once; now if you handle a chicken a few hours after it has taken a couple of pills of camphor, it is completely saturated with it and smells of it. As the parasites lie at the back of the crop, and the camphor is in the crop, the smell of it reaches them, and they die.

Dubbing Game Bantam Cocks (*P. Crowley*).—Except when shown as chickens, Game cocks of every description must be dubbed. Cruel as it may seem, it is not so in reality. It is their nature to fight, and those who may have seen the condition of those that have fought when undubbed, will never call the operation a cruel one. After ten minutes' fighting, a bird fighting with his head furniture entire is, indeed, a pitiable object: his gills hang down in strips, the serrations of his comb are hardly distinguishable, while the comb itself is a mass of bleeding wounds. The deaf ear is generally torn open, and from the purchase given to his antagonist he is a terrible sufferer. All this is avoided by dubbing, and the bird shows for fight, if fighting be necessary, like an "athlete," with his skull round and close-cropped, instead of long hair, affording advantage to his opponent.

Eggs not Hatching (*Château Vallon*).—The cause of the putrefaction of the eggs in question is, that they were originally good, and were sufficiently sat upon to develope the germ of life. This was allowed to perish from some cause, and hence corruption. Each is a dead egg, but it once had life. The probable cause of failure has been, that the hen has left them to feed early in the morning, and while she was off they were chilled. This has been fatal to them. In ordinary seasons, at the end of May, a hen may leave her eggs for hours with impunity, the atmosphere is warm enough to prevent their being chilled, but this year we had in the last week of May from 3° to 7° of frost. There is no hope of eggs that were exposed to this ever producing birds.

Grass Seeds for Sandy Soil for a Poultry Run (*Suffolk Dorking*).—You may, after the potato crop is cleared in July, have the ground prepared; and with the first prospect of rain sow of Italian Rye Grass, 10 lbs.; Lolium perenne, 18 lbs.; Festuca duriuscula, 4 lbs.; Festuca rubra, 4 lbs.; Dactylis glomerata, 4 lbs.; Cynosurus cristatus, 4 lbs.; Poa nemoralis, 2 lbs.; Poa pratensis, 2 lbs.; and Trifolium repens, 8 lbs. Lightly bush-harrow after sowing, and well roll. You will by sowing then gain a season.

Hens Eating Each Other's Feathers (*J. R.*).—Spanish fowls are more prone than any to eat each other's feathers, and, like most bad habits, it finds many imitators. There is no doubt it arises in the first place from the lack of some necessary food—something they require at this season of the year. Those that have no access to grass always do it. We believe if they are supplied with a grass run they always discontinue the habit. A good supply of lettuces cures them, and those that are gone to seed are the best for the purpose. If you cannot give your fowls a grass run, let them have large sods of growing grass, cut with plenty of mould, thrown into their pens daily, and supply them with lettuce freely.

Ducklings Dying in the Shell (*M. H.*).—Your Duck's eggs are set under hens, and you allow them to undergo the same process as if they were fowl's eggs. The ducklings die in the shells because they are too dry, and the inner membrane of the egg becomes consequently so tough that the inmate cannot emerge. If the Duck sat for herself she would be off and in the water night and morning. She would return dripping with water and sit on the eggs, thoroughly wetting them twice every day. If you will do the same your eggs will hatch.

Diarrhœa in Chickens (*W. Z.*).—Your food is too heating. Give them ground oats slaked with water, as thin as can be without waste, for a few days, and, if they will peck it, the tender heart of lettuces. Discontinue eggs, bread, and all stimulants. Earth worms are often useful in removing this malady, which becomes incurable in a few days.

Hen with Inflamed Vent (*G. P.*).—Oil your finger, and with it return the protruding vent. Give the hen a tablespoonful of castor oil, feed on soft food only, and give abundance of lettuce leaves. Her egg-passage is inflamed.

Cockroaches (*A. M. C.*).—To get rid of cockroaches in a kitchen where they swarm, we recommend you to try Chase's Beetle Poison, sold by Mr. T. Chase, Chemist, 14, Holborn Hill, London.

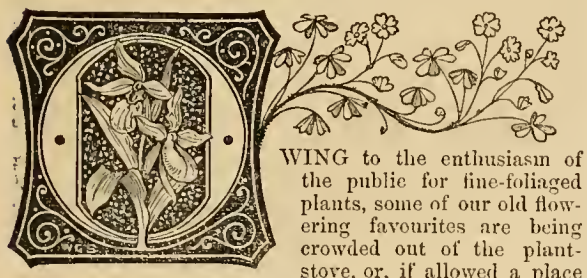
From observations taken near London during the last forty years, the average day temperature of the week is 73.2°; and its night temperature 49.2°. The greatest heat was 93°, on the 22nd, 1846; and the lowest cold 30°, on the 20th, 1865. The greatest fall of rain was 0.72 inch.

ORNAMENTAL-FOLIAGED PLANTS, AND CULTURE OF THE GLOXINIA.



OWING to the enthusiasm of the public for fine-foliaged plants, some of our old flowering favourites are being crowded out of the plant-stove, or, if allowed a place there, are very nearly smothered by some of the recent introductions.

Now, the few remarks I will make are only intended for those having moderate-sized houses, because it is of such houses that I have had charge, and it is in them that I have picked up the measure of experience that I possess. I do not deny any merit to such plants as Alocasia metallica, A. macrorhiza variegata, and others of the same class; and what noble-looking plants we have in Sphærogyne latifolia, Cyanophyllum magnificum, and some others, but they are not adapted for small houses, and I have grieved to sacrifice such plants after growing them into specimens too large for the house.

Then we have the Caladiums: a selection may be made from them, of which the dwarfest and prettiest I know is C. argyrites, and it is suitable for the smallest house. There are, too, the Marantas, of which the best I have seen are M. Veitchii and illustris. The first-named is, I think, the finest "foliage" plant that has been as yet introduced in the class to which it belongs; and those who were privileged to see the handsome specimen exhibited by the Messrs. Veitch, of Chelsea, at the Paris Universal Exhibition in the first week in May, may well be excused if they there and then took a fancy for plants with ornamental foliage. I was sorry to see the pot in which it grew had been smashed during the journey, and the life of the plant consequently endangered.

I am a grower and admirer of some of the plants referred to, but I always contrive to arrange a goodly number of Gloxinias and Achimenes amongst them, and give all an equal share of attention. When the Gloxinias are in flower they are the chief attraction in the house.

Gloxinias are plants of easy culture, and when in flower they will well repay a little extra care bestowed on their cultivation; I will, therefore, offer a few remarks on their culture.

I will begin with propagation. They are increased from leaves, which are taken from the parent plant with a short piece of the leafstalk attached, and inserted round the sides of a 48-sized pot in a mixture of equal parts of yellow loam, turfy peat, and silver sand. A thin layer of sand may be spread over the surface of the soil before inserting the leaves; the pots are then placed on a shelf where they are shaded from the sun, and watered through a fine rose, affording a temperature of 65° or 70° at night. They must be kept moderately moist, and if the leaves stand erect and remain of a green colour they will soon form tubers. Towards the season of rest, as the foliage acquires a yellow tinge, water must be gradually withheld, and they should then be stored away in a dry place where the temperature is not under 40°. I have kept them in a vinery at rest, also in the plant-stove under the stage, laying the pots on their sides, so that the continued dripping from the plants above will not saturate the soil.

About the first week in January, after watering the pots with tepid water, they are placed on a stage along the back wall of a half-span Pine-house immediately above two rows of four-inch hot-water pipes. There is not much circulation of air there.

It is a fact worth mentioning that I have tried the plants along the front of the house where they have more air and light, but I have never found them do so well under these circumstances; so that I now prefer the back part of the house where they do not receive so much of the direct rays of the sun.

As soon as they show above ground I shake them out of the pots, and place one tuber in the centre of a 48-sized pot, the compost used being equal parts of loam, turfy peat, and well-rotted cowdung, with the addition of some broken charcoal and silver sand, which is used in larger or smaller quantities according to the nature of the soil, some soils requiring much more sand than others. If they are well treated the pots will soon be filled with roots. The plants must then be shifted into their flowering pots, using six-inch pots for the smallest and seven-inch for the largest.

As soon as they have done flowering water is gradually withheld, and when the foliage assumes a yellow tinge they are placed in their winter quarters, and treated exactly as recommended for the young plants, using larger-sized pots the second year—namely, six or seven-inch pots to begin with, and shifting into those 8 or 9 inches in diameter, according to the strength of the plants. I never use larger than nine-inch pots, and I have had Gloxinias in pots of that size with from 150 to 200 blooms expanded at one time on a single plant.

I generally grow named varieties, but it is very interesting to save seed from good sorts, I have sown the seed in February, and had the plants in fine flower the same season, numbers of them being as good as the parent.—J. Douglas.

VARIEGATED IVIES.

Now that so much attention is bestowed on various-coloured foliage, would it not be well to endeavour to increase the number of plants combining with that advantage a greater degree of hardiness than the Pelargonium possesses? Successful as cross-breeders have been in producing Pelargoniums rich in colouring and compact in habit (and no one is disposed to give them more credit than myself), still I think if the same skill and attention had been bestowed on plants of a more hardy nature we

might have obtained variegated foliage, of a more lasting character, and adapted to the requirements of the humblest cultivators.

Although success in this direction may be slow of achievement, I nevertheless hope to hear of some progress being made, What I want is simply a substitute for Golden and Silver-edged Pelargoniums that would look as well out of doors in midwinter as these do in summer; and why should we not have such a plant? Do the best Golden or Silver-edged Pelargoniums of the present day, even when at their very best, equal the Golden or Silver-edged Holly, as seen at all times, winter and summer? and why should we not have other plants as hardy as the Holly, clothed in the same golden or silver garb? I should very much like to hear that raisers of Tricolored Pelargoniums had turned their attention to effecting improvements in the Ivy. Their first efforts might prove failures, or the progress might be slow, but it has been the same in the case of other plants with which a good result has been at length attained.

Can any one trace the history of the Gold and Silver-variegated Hollies, their origin, and how they comported themselves in the earlier years of their existence? If so, something useful as regards the treatment of the Ivy might be learned. There are, it is true, Golden and Silver-leaved Ivies, but they fall far short of that clearness of colouring and constancy which the Variegated Hollies present; thus, although at the present time (the end of May), a bed of White-leaved Ivy at this place is very pretty, and a mound covered with the Yellow one is prettier still, yet neither plant retains its beauty. In winter the foliage of the White variety becomes dirty and blotched, and in that of the Golden, green is the rule, yellow the exception; and the latter is anything but clean and handsome. I have had more than one variety of each kind of variegation, but perfection is far from having been as yet attained with either.

I trust that some one will direct his attention to the subject, and that in a few years we shall possess as many varieties of Ivies as we now have of Pelargoniums; and if an equal degree of improvement can be effected in the one plant as in the other, we shall then have a plant capable of doing duty at all seasons. The Holly may be pointed out as such, why not the Ivy? The smooth glossiness of the leaves is much alike in both plants, and why should not a similar degree of variegation be produced in the Ivy to that which the Holly presents? The Japanese have done much in transforming the foliage of plants, and, no doubt, they could change that of the Ivy. There are other plants besides the Ivy, which I believe capable of being improved for bedding purposes, but its clear, bright foliage, and its convenient habit of making itself at home everywhere, and adapting itself to all forms, point it out as being one of the best to operate upon. Whoever can favour us with a Cloth of Gold, a Silver Queen, or, perhaps, a Mrs. Pollock Ivy, will deserve equal honours with those who supplied us with the Pelargoniums of the same names.—J. Robson.

USE OF A GLASS-ENCLOSED OUTSIDE VINE BORDER.

I have a lean-to vinery, south aspect, in which Black Hamburghs were begun to be forced on the 1st of February. On the outside is a border 6 feet wide, 50 feet long, covered with sashes on hinges to lift. Between the border and the vinery are portable lights, so as to remove when necessary, and render the two of equal temperature. The Vine border outside so covered I am desirous of turning to the best marketable account, if this can be done without losing in one way what we gain in another. I have thought of two plans: one to raise and bring on Strawberries in pots, and plant out on, say, 1st of October—they will probably fruit in May; and on, say, 1st of June, to plant out strong Melon plants not requiring bottom heat—they will have fruited if at all by October 1st; then top-dress and give liquid manure to balance that which the two crops may take from the soil. The other, and apparently less desirable plan, is to plant Vines after the manner of the curate's vinery. The drawbacks to this are, first, shallowness of border, being only 2 feet at back from the glass to the surface of the earth, and 1 foot in front; the difficulty in thinning without injury to the bunches; and, thirdly, the interference of the roots of one set of Vines with the other.—Old Subscriber.

[We decidedly consider that all outside Vine borders are better uncropped, or having but little in them in summer. As your outside border is only 6 feet wide, and the inside one is wide, you might dispense with the outside one altogether. As it is there, it will be to the benefit of the Vines to have it covered over with glass in the way of a pit; and as there is a means of heating that pit from the house by sliding sashes, it would do no harm to the Vines to keep Strawberry plants and other things in that pit on the surface of the border in winter and spring. For this purpose, in the way of profit, we would recommend Keens' Seedling; but we would grow the plants in pots, instead of planting them out, for several reasons, such as having them more under control, and being able at once to take out a barren plant. As to their future use, they may be planted out in the open ground, and they will bear immensely the following year; or they may stand at the back of a north wall for a couple of months, have the earth shaken away, and be repotted and grown on for the following year, when most likely they will bear a great quantity of fruit, though individually not so fine as would be procured from younger plants obtained from early layers, potted, and the pots well filled with roots before autumn. From what we stated at first, we would rather not grow Melons and Cucumbers in such a place in summer, not merely on account of the shade they would give to the ground, but for the likelihood of having fly or thrips transferred by such crops to the Vines. We have done so, however, exactly as you propose, and with good success; but, as a matter of advice, we would recommend some rough backs and fronts to receive the sashes in summer elsewhere. If the sashes could remain a few weeks over the border after the Strawberries were removed it would benefit the Vine roots. We did not gather Strawberries out of doors until the 14th of June, and therefore Strawberries might be had until they came plentifully out of doors. Strawberries at all forced go so much to leaf when planted out that we recommend pots.]

GLADIOLUSES AT FONTAINEBLEAU.

The readers of The Journal of Horticulture will have no difficulty in understanding the reason of my paying a visit to Fontainebleau. It was not the grand old château with its historic associations which brought me there, for so little did this enter into my calculations, that I went there the only day in the week on which it is closed (Monday); nor was it to see its much-talked-of forest that proved to be the attraction; though I must say, as in duty bound, that these were high considerations with some of my party to which I am bound to pay all deference; and certainly if I had taken the journey from Paris for the purpose of seeing the forest I should have felt wofully taken in. Like everything of the kind that I have seen in France, it is spoiled by its excessive regularity. Straight avenues, and central crosses from which these diverge, meet you on all sides, one as like the other as possible; while the trees themselves are allowed to grow so thickly together, that very few fine specimens are to be seen of really fine trees. In a few places there are some wilder spots—one especially, from whence you can obtain a grand view over the forest, stretching on all sides of you; but having, as I had, lively recollections of many a grandly wooded scene in old England, with its magnificent Oaks and glorious Beeches, under whose shade, like Tityrus of old, I had stretched my wearied limbs, I must confess that feelings of disappointment formed the largest ingredient in my thoughts when we had finished our drive. No, it was neither of these, but a courteous invitation from the Coryphæus of Gladioli-growers, Mons. Souchet, the *jardinier en chef* of the château, that drew me to Fontainebleau; and had I nothing to think of as the result of my visit but the truly hospitable and amiable reception we met with from him and his good wife. I should ever recollect with feelings of deepest pleasure the very pleasant day I spent with him; but when this can be supplemented with a long talk on a flower which is a favourite with us both, and which ought to be far more popular than it is, my readers will readily believe that it was a source of no little enjoyment.

Mons. Souchet grows nothing else but the Gladiolus; it is his *spécialité*, and has been for many years. Indeed the taste is hereditary, for his father, upwards of thirty years ago, turned his attention to it, and originated many fine varieties of the Ramosus section; but these have been long since left behind by the varieties raised by his son—varieties which are increasing in beauty every year, and constitute one of the greatest ornaments of our gardens in the autumn. He occupies some twenty-six acres of ground (twelve hectares), and has annually

from four to five acres under culture with the Gladiolus alone. Nor does he practise succession of crops, for he allows the portion of his land not occupied to be fallow, so that every year his roots are planted in not only fresh soil, but in soil that has rested. This soil is very light, and he does not hesitate to enrich it with considerable quantities of manure, although he believes that this may be overdone. We sometimes talk of our difficulties in the cultivation of the flower; but what are they to his? Who knows what the "ver blanc" is? Happy those who are in perfect ignorance of the pest, which is no other than the larva of the cockchafer, or May bug of our school days. This is a tremendous pest in France, especially in those parts nearest the forest. The perfect insect strips many of the trees quite bare; but the larva is the fellow for mischief. No schoolboy has a more accommodating appetite than he has. Let him once find his way into the ground, and shrubs, young trees, roots, all vanish before him as rapidly as the three-cornered tarts, jam puffs, and Bath buns do before the hungry scholars of Dotheboys Hall. As we went through the grounds of the château we passed Lilac trees, young Conifers, &c., all in a state of decay. "Ah!" said M. Souchet, "that is the 'ver blanc.'" As we were leaving him for Paris in the dusk of the evening he said, "Ah! my work is not yet done for the day. I must be off to my grounds, for I have fifty or sixty women and boys coming in to gather ce *terrible enfant*." At this time of the year it is on the wing. The female drops on the ground, and, if time is allowed her, deposits her eggs, and thus the mischief is done. Hence M. Souchet's plan is to "catch them alive" before they have time to effect their amiable object, and to destroy them. This is actually done by bushels at a time, and thus he escapes with comparative impunity.

This cockchafer grub, however, is not M. Souchet's only enemy. I observed that his bulbs were planted in very shallow trenches. Supposing this to be for the convenience of watering them, I made an observation to that effect. "Oh, no!" was his reply, "but it is to avoid the attacks of a grub which we have here; and I find that if the bulb is planted shallow it is not attacked. I afterwards, when the bulbs have well started, fill in the trenches with earth." Plague No. 2, thought I, from which we are pretty well free. I then asked him about plague No. 3, which we do know something of—the spot. This he believes to arise in a great measure from the practice of planting the bulbs in the same ground in successive years. Whether this be quite so or not I cannot say, but his lengthened experience entitles him to speak as with authority; and he assured me that he was himself very little troubled with it, attributing that to the practice of changing his ground, which he so rigidly adopts. Where bulbs are slightly affected by it there is a chance of recovery; but even then they ought to be planted in some place apart, and not in the beds. When they are deeply affected by it nothing avails, and the bulbs perish.

I asked M. Souchet with regard to the size of the bulbs, and how it affected their blooming, and found that he quite agreed with me, that the medium-sized bulbs (which indeed would be called small), gave the best blooms. Large bulbs are pretty sure to throw up several trusses, and for those who wish to propagate them this is all very well; but simply for bloom the smaller bulbs are best. He showed me, for instance, some about the size of a large Filbert. These, he said, will bloom well, and they will make beautifully symmetrical bulbs for next year. Even little "bulbules" not bigger than a Marrow-fat Pea he said would bloom; and, as I mentioned last autumn, this had been confirmed by my own experience. In some varieties this is more remarkably the case. Reine Victoria, for example, a fine white, never blooms well from a large bulb; and small ones, which a buyer would, did he not know this, invariably reject, are sure to give a satisfactory spike. There are the same idiosyncracies in these as in every other flower—some blooming early and some late, some always certain and others uncertain. Thus that noble variety Shakspeare, which was let out last year, is a very early bloomer, will always start in its dry state, and requires to be planted long before the others; while Maréchal Vaillant again, another fine sort, was so uncertain, that M. Souchet had some doubt whether at one time he would send it out. These are peculiarities which the grower of every florists' flower knows about, and which he can only know by the lessons of experience. These lessons are sometimes gained at a severe cost; they make one the more careful when they have been learned.

I found that as to varieties we had not much difference of opinion. He was exceedingly modest as to his own merits in the matter, but at the same time stated what we all know, that the best of those now grown are his productions; and he has promised to supply me with a list of those sent out by him in each year, and which I hope at some future time to lay before the readers of the Journal. On speaking to him of the defective form of some of his flowers, such as Lord Byron, he frankly acknowledged it; but then added, "But what a colour! Could I discard it?" Ad. Broigniart and Princess Marie de Cambridge, both flowers of this year, he thought very fine, and likely to be general favourites; the former for its peculiarly novel colour, and the latter for its great purity. At the same time he added he was quite astonished at the manner in which old varieties that he should long since have discarded are still inquired after: possibly their cheapness is the cause of this. I should, however, state that M. Souchet does not himself sell his bulbs. They are supplied by him to five Paris houses—Messrs. Vilmorin, Andrieux, et Cie., Quai de la Mégisserie; Messrs. Thibaut et Keteleer, Rue de Charonne; Mons. Charles Verdier, Rue de Marché aux Chevaux; Mons. Eugène Verdier, Rue Dunois; and Mons. Loise, Quai de la Mégisserie; and English buyers can deal directly with these houses.

Many of the readers of the Journal will doubtless be visiting Paris this summer. I would advise any lovers of the Gladiolus, if they possibly can, to make their's about the middle of August, and take a day at Fontainebleau. I was requested by Mons. Souchet to say that he should be most happy to show his collection to any amateur at that time; but I must at the same time warn them that they must be prepared to speak with him in his own language, for neither he nor his amiable wife understands a word of English, and I can assure them that they will meet with a kindness of reception which cannot be excelled even in the wide and generous hospitality of the Emerald Isle.—D., *Deal*.

DUTY-FREE TOBACCO.

I am obliged by Mr. Tafe's courteous notice of my inquiries on this subject. In common with all cultivators of flowers, I hail the boon which he announces as a kind and graceful concession from the Government. There are, however, one or two further points on which, as an amateur gardener, I solicit information. Perhaps Mr. Tafe will be so good as to assure us.

The advertisement speaks of the prepared tobacco, "either as a powder, or . . . . as a wash;" but are we limited to these two modes of application? I fear neither would be of much avail for houses in which costly and delicate plants are grown. Who would powder his flowering plants with snuff, or syringe them with tobacco water? And the anointing of each leaf and twig with a sponge or brush is hopelessly tedious. Presuming, however, that the powder can be burned on an iron plate, or on coals, for fumigation—the only mode likely to be of much use for plant-houses—an important question arises from the presence of the sulphur. The fumes of burning sulphur are fatal to plants, unless applied with extreme caution. Is the proportional amount of sulphur in a given quantity of the new powder so small as to permit the mixture to be burned in a plant-house without danger? We need to have distinct assurances on this point before we can expose our valuable plants to risk. If it prove that there is no danger on this score, then it seems probable that the coarser form advertised for agriculturists, at 28*s.* per cwt., would be the most suitable for fumigation, unless there is some latent objection. All this we shall be glad to know.—P. H. Gosse, F.R.S., *Torquay*.

That the public is now enabled to obtain ground tobacco free of duty, is owing solely to the exertions of the inventor of the "Ground and Cylinder Vineries."—Observer.

The Recent Frost.—I was fishing a few days since in the Bray, which runs through one of the most warm and sheltered valleys in our usually genial climate (Barnstaple). I was amazed and grieved at the melancholy appearance of the woods which clothe the hill sides. The Oak coppices appeared as if a fire had passed over them, the leaves brown, the young shoots quite killed. The shoots of the Ash were as much damaged; the Alder shoots not quite so much injured. The only vegetation that appeared to have entirely escaped injury was the Hazel and Mountain Ash. Ferns of all sorts were cut down and brown as in winter, and in some places the Gorse was entirely killed. The damage to the growing woods and

coppices will be very great, they will scarcely recover this year. A cold north-west wind and frosty mornings have almost cleared our Pear crop. Apples will be much better. Plums, and wall fruit generally, though well set, have dropped off.—J. M. M.

ROYAL HORTICULTURAL SOCIETY.

Weekly Show, *June 15th.*—Though several prizes were offered, only one exhibitor put in an appearance—namely, Mr. A. Wilkie, gardener, Oak Lodge, Addison Road, Kensington. A third prize was awarded him for a collection of cut Roses, and he received three extra prizes for six Fuchsias, six Pelargoniums, and a collection of miscellaneous plants. A collection of Gloxinias, Begonias, Pelargoniums, &c., from the gardens of the Society at Chiswick, made up a small but interesting exhibition.

Floral Committee, *June 18th.*—Among other plants exhibited on this occasion, a single flower of a seedling Cactus, sent by Mrs. Merrick, was brought before the Committee, but it proved to be in no way distinct from known varieties. Messrs. Downie, Laird, & Laing received a second-class certificate for Nosegay Pelargonium Floribundum, and a similar award for Nosegay Pelargonium Right Hon. G. Hardy, both plants producing fine trusses, but not very distinct from or better than many others. The same firm also sent Nosegay Comet, a promising variety with a compact truss; and a Fancy Pelargonium called Mr. J. W. Todd. Mr. J. Davidson, Highfield Park, Hants, exhibited Pelargonium Emily, not equal to Rose Queen, &c., and three specimens of variegated Laurels, very faintly variegated, and by no means an improvement as regards the foliage. Messrs. Osborn sent a group of plants, among them one well known but rarely seen, Gordonia javanica. It was deservedly much admired, and was awarded a special certificate. Mr. Lee, Albion Road, Hammersmith, sent a seedling Lobelia named Lee's Dwarf Blue, very compact in habit, distinct in colour, and a decidedly useful plant. It received a first-class certificate. Lobelia Fawn, pale lavender; and Lobelia Ultramarine, came from the same exhibitor. Mr. Shortt, gardener to Viscount Eversley, Heckfield, exhibited a cut specimen of Pentstemon Cobœa vera, a very handsome form, with large white flowers deeply veined; and Ruscus aculeatus, covered with berries, as standard plants for table decoration; the berries had been produced by careful impregnation.

Messrs. J. & C. Lee sent seedling Lobelia Sparkler, Hypericum (chinense) monogynum, and Carex pilulifera var. aurea. Mr. Bull exhibited a specimen of Drosera filiforme, a curious plant; likewise a collection of Cypripediums, Bertolonias, Podocarpus, &c., for which a special certificate was awarded. Mr. John Parker, gardener to S. G. Cooper, Esq., brought a variegated form of Lobelia speciosa, which appeared to be L. speciosa spoiled. Mr. Whitehorn sent several seedling Pelargoniums—Purity and Pauline, show flowers; and Purple King, a beautiful form of Rollisson's Unique, which might be much more appropriately named Crimson King. This plant we hope to see shown again; it is very distinct, and will be useful.

Mr. Mann, Brentwood, sent some good seedling Zonal Pelargoniums, but the specimens were too small to allow of judgment being passed upon them. A Nosegay called Novelty well deserved its name, but it was quite useless. Nosegay The Baron; Guardsman, a promising Zonal light orange, &c., were also shown by Mr. Mann; as well as Zonal Startler, Christabel, Bridesmaid, and North Star, a bright scarlet. These plants we hope to see again in better condition: the specimens were too young and too small for any fair decision as to merit. Mr. Tirebuck, Luton Nursery, sent several seedling Zonal Pelargoniums, but none of them new or distinct. Richard Keely, with bright yellow foliage, was the most distinct, and may prove useful. Crimson Cushion and eight others were of no use, not being distinct from known varieties. Mr. Kimberley exhibited a spotted seedling Show Pelargonium, Grand Arab.

Messrs. Veitch sent Dendrobium Bensoniæ, sweet-scented, which received a first-class certificate; also Dendrobium species, with small insignificant flowers. Mr. R. Warner received a special certificate for a very fine collection of cut specimens of Orchids. Mr. Sherratt, gardener to James Bateman, Esq., Knypersley, was awarded a first-class certificate for Miltonia spectabilis var. rosea, a very beautiful plant. Mr. Anderson, gardener to T. Dawson, Esq., Meadow Bank, Uddingstone, near Glasgow, received a first-class certificate for a beautiful new Odontoglossum, called roseum; and Lord Egerton of Tatton received a special certificate for a very superb spike of Aërides Fieldingii. This was a marvellous specimen, having eight branches besides the central spike of flowers. So unusually fine was this specimen that the Committee recommended it for the Lindley medal, which the Council most readily granted. W. W. Buller, Esq., exhibited Odontoglossum flavescens, for which a second-class certificate was awarded. A small collection of Orchids was sent from the Society's gardens, also some seedling Caladiums; some of the latter, being of great promise, will be sent to the Committee again, when they will, without doubt, receive their proper award.

Fruit Committee.—Mr. Tillery, of Welbeck, sent three dishes of Strawberries grown under glass. They were fine specimens, and Mr. Tillery stated in a letter that he had been gathering fruit of the same size and quality ever since the beginning of May. The plants were grown in pots only 5 inches wide and 6 inches deep, and the fruit was thinned out so that each plant carried only two fruits. They were stood on shelves, which held about half an inch of soot water. The sorts were Ingram's Prince of Wales, Empress Eugénie, both excellent in flavour, and Reeves's Eclipse, which was not so rich. The Committee awarded them a special certificate. Messrs. J. & C. Lee, of Hammersmith, exhibited fruit of "The Lady" Strawberry. The fruit was large, but being not ripe had no flavour. Plants were also exhibited which shewed the highly prolific character of this variety.

Messrs. Wood & Ingram sent specimens of the fruit of a small oblate Apple veined with russet, which appears to be Grange Apple, and which was perfectly sound, and of good quality.

Mr. Shortt, gardener to Lord Eversley, of Heckfield, sent a fruit of Passiflora quadrangularis under the name of macrocarpa. It was of large size, and weighed 3 lbs. 9 ozs., but was not ripe. Mr. Shortt also sent specimens of a hybrid Melon called Golden Eversley, which, however, was overripe, and the flavour flat. He also sent four varieties of early Potatoes—viz., Paterson's Early Red Kidney, Early Handsworth, Rivera's Royal Kidney, and Old Ashleaf Kidney, all of which were planted on the 6th of March in the open ground, and the tubers exhibited of each were ten of the largest, selected from three plants. James Bateman, Esq., of Knypersley, sent a dish of forced Peaches.

Several dishes of Strawberries were sent from the Society's Garden at Chiswick, among which the best-flavoured were President, Sir Joseph Paxton, and Napoleon III. Prince Imperial was highly flavoured with a fine aroma; Souvenir de Kieff is a large conical Strawberry, solid flesh, and with a fine brisk decided flavour; La Constante was firm, solid, and with a fine flavour.

General Meeting.—Sir Roderick I. Murchison, Bart., in the chair. After five new Fellows had been elected, and the Llangynwyd Cottage Garden Society, Merthyr Tydvil Floral and Horticultural Society, and Newport (Salop) Floral and Horticultural Society had been admitted into union with the Society, Mr. Shortt offered a few remarks on Passiflora "macrocarpa," which he stated to be of Brazilian origin, and considered different from P. quadrangularis, for which it had been taken. The plant on which the fruit exhibited was produced was not ten months old, and any one who could give moderate heat and moisture could grow it in an eight-inch pot. He himself had plants in flower in five and six-inch pots. Mr. Shortt concluded by remarking that the splendid Tacsonia Van-Volxemi also produces edible fruit.

The Rev. M. J. Berkeley said that with the exception of the Orchids there were few plants that required any observation. The first to which he would direct notice was Gordonia javanica, belonging to the same natural order as the Tea plant. Gordonias were bog plants, and in North America their bark was extensively used for tanning. Mr. Shortt's fruiting specimens of Butcher's Broom next claimed attention, and their ornamental appearance for dinner-table decoration was pointed out. The plant, however, being dicœcious, it was difficult to fruit it except by artificial impregnation, as Mr. Shortt had done. After noticing Limnanthes Douglasii, as a very pretty spring bedding plant if sown in autumn, Mr. Berkeley directed attention to a beautiful specimen of a fasciated Pinus Pinaster, in which the lower part was spirally twisted, and bore normal cones, while the subordinate upper branches were fasciated. Abnormal pressure in the bud, he remarked, would not account for this example of fasciation. Though so much had lately been said about the foliage of Zonal Pelargoniums, he would venture to make a few more remarks on the subject. A doubt had been expressed whether it was possible for a white ground to become pink; but he exhibited two leaves of the same variety, L'Elegante, shown by Mr. Ball, the one with white, the other with pink edges, the result, he believed, solely of different treatment, the plant in the former case being subjected to ordinary treatment, and in the latter kept dry and near the light. Another curious subject for investigation was the appearance of the leaves of a hybrid between the common Zonal and the Ivy-leaved Pelargonium, and in which the upper part of the leaf partakes of the Zonal character, whilst the lower part has that of the Ivy-leaved Pelargonium, and the flowers are partly those of the Zonal, partly of the Ivy-leaved parent. This case could not be accounted for in the same way as the production of Cytisus Adami, by cell-grafting, and tended to show that the theory which had been formed respecting it was entirely wrong; at the same time the mode of action of the pollen on the embryo sac was not known. Schleiden supposed that the end of the pollen-tube entered the embryo sac and became a new plant; but, probably, the action of endosmose and exosmose would account for the passage of the pollen influence into the sac; the subject, however, was one of those mysteries which at present we are unable to explain. Passing to another subject, Mr. Berkeley said that about a month ago he was in the grounds of Sir Frederick Pollock, at Hatton, near Hounslow, and observed that four plants of Cupressus macrocarpa, once the pride of the garden, had perished. On examining them he found that the whole of the plant was covered with the spores of a fungus (Pestalozzia funerea), which under the microscope formed one of the most beautiful objects he had ever seen. Some years ago the Camellias in one of the principal nurseries near Canterbury were devastated by an allied species of fungus, originally discovered in France by M. Dupin.

Mr. Bateman said, that though all knew the splendid specimens of

Orchids which Mr. Anderson, Mr. Dawson's gardener at Meadow Bank, was in the habit of exhibiting from time to time, yet he had never sent finer than those which he had exhibited on this occasion. Beautiful as his bunch of Odontoglossum Pescatorei was, it only represented a fraction of the blossom on the plant from which it was cut, and on which no less than three hundred flowers were counted; but, glorious as Mr. Anderson's Odontoglossum was, even it was surpassed by the cut specimen of Aërides Fieldingii, from Lord Egerton of Tatton, which was the most magnificent example of that species which had ever been exhibited, and to which, on the recommendation of the Floral Committee, the Lindley medal had been awarded Mr. Bateman then noticed two or three small specimens of Orchids, and especially the little Peruvian Odontoglossum roseum, which, though beautiful *in miniuis*, would present a still more glorious appearance when larger specimens were obtained. Miltonia spectabilis, of which his own gardener had sent a fine variety called rosea, was also mentioned as having been obtained through Messrs. Low; likewise Epidendrum vitellinum, from Mr. Anderson, which was figured twenty-five years ago by Dr. Lindley, from dried specimens, but when the plant was flowered some years later by Mr. Barker, every one considered the drawing exaggerated, so poor were the blossoms then; but now that the cultivation of the plant, which comes from an elevation of 7-8000 feet, is conducted on the cool—that is, sensible—mode of treatment, the original representation utterly failed to do justice to its beauty. Beautiful, however, as Mr. Anderson's example of this Epidendrum was, Mr. Bateman said he had seen one far superior a day or two before at Mr. Day's, at Tottenham.

Coming now to the immediate subject of his lecture, Lælia majalis or Flor de Mayo, it was one of the few Orchids which was fortunate in having a history as well as a name—in fact, many names, the native one being Itzamaquee; besides which it had two or three Spanish, and three or four Latin names. It was all very well for old Rumphius to say that the Orchids are the aristocrats of the vegetable kingdom, but not one in a hundred of them had ever been heard of before the present century, and in classical or heroic ages they were unknown. No one, not even the Chairman, had ever found a fossil Orchid. Any Orchid, even, whose history could be traced back to the conquest—of America he meant—would hold a distinguished place. It had been said that when the French took possession of a settlement the first thing they did was to establish a *café*, and in a like manner the Spaniards were in the custom of erecting a church. For the elaborate services of these churches the Spaniards, being ignorant of the resources of their new possessions, at first carried with them their old-world flowers; but they soon discovered the value of Orchids for church decoration. In connection with this part of the subject he might mention that his old friend Mr. Skinner had sent home from Guatemala some bulbs which proved to be no other than those of the common white Lily, which had doubtless been taken out for the very purpose, and had run wild. The value of Orchids for church decoration having been discovered, as before remarked, they were largely employed for the purpose; and the names of the saints' days and festivals for which they were suitable were applied to them, and of these Mr. Batemen cited a number, of which "Flor de Mayo" was one. Knowing the extensive use of Orchids in church decoration, Mr. Skinner, he might remark, when he wanted to know what Orchids were in season, always went to church to look at the altar decorations. To proceed with the history of Lælia majalis, the first naturalist who went to Mexico was Hernandez, who published in 1648, at Rome, a book, in the frontispiece of which two Orchids were represented, one of which was the beautiful Lælia majalis. Humboldt was the next to notice it under the name of Bletia speciosa, as one of those beautiful Orchids the recollection of which no time could efface. About the same time Lexarza, who went out to Mexico, failing to recognise the plant as described by Humboldt, called it Bletia grandiflora. His description of this and other Orchids so impressed the youthful Reichenbach, that he wanted to visit Mexico himself; but this proved unnecessary, for Mr. Barker dispatched a traveller thither, who sent a number of plants, which, arriving in midwinter, were sent home in blankets, but they never flowered. Next M. Deschamps, in 1837, exactly thirty years ago, brought home a cartload, for which he asked enormous prices, and eventually he was glad to sell the plants at a cheap rate; but they all disappeared without flowering, except one, which was purchased by Mr. Dillwyn Llewelyn, and which was figured in Mr. Bateman's work on the Orchids of Mexico and Guatemala, and by Dr. Lindley in the "Botanical Register," 1844. The drawing in the former work was made under Dr. Lindley's direction, who thought the plant produced four or five flowers; but never, except under exceptional circumstances, did it produce more than two on a scape. Just as Humboldt failed to make his description of the plant intelligible to Lexarza, so the latter to Lindley, who called the plant first Lælia Grahami, and afterwards L. majalis, and though Reichenbach wishes to go back to L. speciosa, Lælia majalis it is to cultivators, and so it ever will be.

Mr. Bateman then mentioned that Mr. Anderson had communicated to him his treatment of the plant, which differs materially from that pursued by Messrs. Backhouse, as stated also to him (Mr. Bateman), in a letter from his friend Mr. Wentworth Buller. Mr. Anderson grows the plant in a kind of Wardian case, where the temperature rises by sun in the day to 80°, but is cool at night and in winter. Mr. Buller, on the other hand, states that it is kept by Messrs. Backhouse in a house where the temperature in winter ranges from 45° to 53°, and sometimes falls as low as 37°, no fire heat being given unless the temperature declines below 40°. Abundant ventilation is likewise afforded, the ventilators being opened at night when the external temperature permits. In the same house was growing Epidendrum ernbescens, likewise figured in Mr. Bateman's superb work, and far surpassing any plants of the species which Mr. Buller had seen elsewhere. Mr. Bateman, in concluding, then remarked that success in the cultivation of the latter plant and of the Lælia would appear rather to depend on abundance of air kept moving than on temperature.

The Chairman, in returning Mr. Bateman the thanks of the meeting for his interesting remarks, said that though a fossil Orchid had never yet been discovered, he would endeavour to stimulate geologists to search after such.

Mr. Bateman, in replying, asked to be allowed to add an observation which he had omitted to make at the proper time—namely, that some of the Orchids which Mr. Anderson had sent were growing on flat tiles.

ROYAL BOTANIC SOCIETY'S SHOW.

At the second great Show of this Society, held yesterday, there was again an excellent display of stove and greenhouse flowering and fine-foliaged plants, many of which were in greater perfection than on the last occasion. Pelargoniums and other florists' flowers were also numerously exhibited; and of Fuchsias we have rarely seen finer than some of the plants shown by Mr. Brockwell and others. Large and most interesting collections of new plants came from Messrs. Veitch, Mr. Bull, and others. Orchids were fairly represented, though not so numerous as we have seen them in former years. Among fruit there were numerous and well-ripened bunches of Black Hamburgh Grapes, fine bunches of Black Prince from Mr. Meads, gardener to Raikes Carrie, Esq., Minley Manor; some very good Providence Pines, excellent Peaches, Nectarines, and Strawberries.

CHELTENHAM HORTICULTURAL SHOW.

(From a Correspondent.)

The Cheltenham Horticultural Society's second Show for the season was held on the 12th of June in the beautiful grounds of Pittville Spa, and the afternoon being fine attracted a numerous concourse of visitors.

The collections of ornamental-foliaged plants, grouped for effect, exhibited by T. P. W. Butt, Esq., and Mr. Heath, were particularly worthy of remark, as were the stove and greenhouse plants from Mr. Butt and Mr. Cypher. Fine collections of British Ferns were shown by Sir Alexander Ramsay, Bart., and Mr. Pilgrim; and of Pelargoniums by Mr. Hopwood, Miss Douglas, and Mr. Heath. There was a severe competition in vases of cut flowers, arranged in threes for the dinner table; those shown by Lady Ramsay, Rev. W. Coventry, Capt. Fickell, G. Loutheau, Esq., and Mr. Cypher being exceedingly elegant and artistic in their arrangement. Cut Roses received their full share of attention, and were well shown. The boxes contributed by Mr. C. Brydges, the Rev. W. Coventry, and T. W. Potter, Esq., were particularly good.

The Show of vegetables was unusually good. Cauliflower, Asparagus, Peas, Kidney Beans, new Potatoes, Mushrooms, and baskets of Salad were excellent. The last were tastefully designed, well arranged and well filled. That from Mr. E. Smith was surprisingly good.

The show of fruit was not so good as in former years, although there were some fine dishes of Grapes, Peaches, Strawberries, Cherries, and Melons.

ROSES INJURED BY FROST.

"E. H.'s" case is, I believe, not a solitary one, as I have observed something of the kind here (Staplehurst), though my Roses have suffered but little from frost, almost my whole stock being dwarfs on their own roots, and many of them plants eight or ten years old. Except that they have suffered a little at the tips during the severe frost of January, I see no difference in their appearance this season from that which they exhibit in other years; they seem to bloom quite as strongly and as freely. This remark refers more particularly to the Hybrid Perpetuals. The damage done to the China varieties was more severe; but not a plant has been killed, and they are blooming as well as before, having only received a more severe pruning than usual. Of Tea Roses I have not many; but I find two plants against a south-west wall have been injured. On one of them the shoots, appearing to be still alive, were left at the usual pruning time in March, and started into life; but since then portions have died back, and the plant is far from healthy.

The above is the only case of a plant having been more injured by the frost than it at first appeared to be; while, on the contrary, many subjects that were pronounced by fair judges dead, are breaking out in different portions of their branches, as Bays, Laurustinus, Majorca Box, Euonymus, and some Conifers. These have never been meddled with, as I am not an advocate for cutting down if it can be avoided. A fine bushy tree of

Pinus insignis, upwards of 40 feet high, was quite red, and, on examination, its twigs showed what appeared to be hopeless deadness in its pith, as "E. H." describes in his Roses; yet the tips seem to have escaped destruction, as it is pushing out green all over; and although it will not be so handsome for a year or two, I hope it will do good service yet. Some other plants, such as Phillyreas, exhibited similar injury, and are likewise recovering, the tips of the last year's wood being in most cases all that are really lost; but why should these plants have shown greater injury than they have received, whilst, on the contrary, the Rose in question was more hurt than it really seemed to be, as so many shoots have died since the tree started into growth?

I may add that two old standard Gloire de Dijon Tea Roses are quite uninjured, although growing close to where Laurustinus was much damaged. Trailing Roses have suffered only a little; yet some of them, in the way of the one alluded to, and a plant of Jasminum nudiflorum, growing against a pillar in a very cold and exposed place, has been killed to the ground, but is starting again. I find that in the open ground Leycesteria formosa and Phygelius capensis are both killed to the snow line, and a plant of the latter against a wall has suffered a like fate; but as neither of them presents so hard and firm a woody stem as most shrubs, their being injured need not be wondered at. I hear of several Evergreen Oaks, thought to be dead, coming to life again. After all, we must not complain too much if some of our Roses suffer more than could be wished, as the total number of subjects absolutely lost is much less than was at one time thought to be the case.—J. R.

PYRETHRUMS AND PÆONIES AT VERSAILLES NURSERY, HAMMERSMITH.

The Messrs. Salters' collection of these very magnificent flowers is now in perfection, and all persons interested in horticulture would do well to avail themselves of an opportunity of visiting this nursery.

It is very interesting to see the progress, by cultivation, made in the Pyrethrum. From a single white flower double varieties have been raised, varying in colour from the deepest carmine rose to pure white; the flowers are perfect in form, and the foliage of the plants elegant. They must be seen to form any correct notion of their beauty; and grown as they are by the Messrs. Salter in large beds, the effect is quite startling.

Of the Chinese Pæonies too much cannot be said. They are gorgeous in colour, and yet exquisitely delicate. Some of the light varieties are sweetly scented, and the flowers standing up among the dark rich foliage make them very conspicuous. It is most remarkable that these hardy and useful plants are not more generally cultivated. No one should leave the gardens without inspecting a novel and beautiful design in the application of some of the low-growing Sedums.

Mr. Alfred Salter has been most successful, and exhibited great taste in the use he has made of these plants. The uneven surface is completely carpeted with various shades of colour, in which small groups of Cacti and other succulent plants are most judiciously introduced. This arrangement of these peculiar plants is most effective and novel. There is little doubt but that the idea will be followed out by many amateurs. The collection of Zonal Pelargoniums is very interesting, and some of the finest varieties both English and foreign are to be seen. One remarkable feature in the greenhouses is the total absence of Variegated or Versicolor Pelargoniums, when the finest collection in England of variegated plants is distributed all over the grounds.—J. D.

INFLUENCE OF THE GRAFT ON THE STOCK.

It has been a mooted question for years whether the graft exerts any influence on the stock, and if so, how much? The judgment of observers is not unanimous, the most part urging that there is no influence whatever. The stock has an influence on the graft, however, as the process of dwarfing demonstrates. A fast grower does not develope itself with nearly so much vigour on a weak-growing stock as on a fast one. This, indeed, is the philosophy of dwarf fruit-tree culture. Now, as it is a pretty well known fact that in almost all the active forces of nature two forces can scarcely combine without mutual influence on each other, we might almost expect some difference in the stock by the influence of the graft, as well as to find the graft influenced by the stock.

Experiments have often been made to test this matter, but little evidence has been collected in favour of the graft's influence. Muscat Grapes grafted on Hamburghs still produce Muscat Grapes—and the upper half of a White Beet has been grafted on a Red one when young, and the line of red and white has been preserved through the whole life of the Beet; and we believe a great many similar experiments with other things have resulted in the same way. Yet we see things sometimes that scarcely admit of explanation in our present state of knowledge, that would indicate that some mutual influence is probable as well as possible.

If we take two Quince stocks of equal strength and vigour, grow them as nearly as may be in similar circumstances, and graft on one a strong-growing variety of Pear, and on the other a weak variety, we find the Quince stock on the fast-growing Pear growing faster than the stock of the weak-growing Pear; and, indeed, we can get wood of a Quince on which a Pear has been grafted much thicker than any Quince would ever grow in the same time. So far as growth is concerned, then, the Pear graft has an influence; and if there is an influence in one point why may there not be in some others?

We have noticed another instance where an influence on the stock was perceptible. A tree of White Doyenné Pear, which had borne nothing but worthless cracked fruit for years, had, three years ago, all its upper branches grafted with Bartletts, and the lower branches of the White Doyenné were suffered to remain. The growth of the Bartletts has been very strong, and their strength has been evidently communicated to the stock for several inches below the point of union. On one of these branches a sprout of the Butter Pear, growing just below the point of union, had been overlooked in the grafting, and the shoots bore last year clean perfect fruit, all the rest of the tree being cracked and worthless as heretofore. The most probable influence in accounting for this is, that this shoot had received its conditions of health from the Bartlett shoot above it.

That there is really a downward influence of some kind in plants is shown by occasional circumstances which vegetable physiologists stow away in their cabinets of curiosities. Some years ago the late Mr. William Reid, of Elizabeth, New Jersey, showed some variegated Willows which he had grafted on some plain-leaved varieties, and the variegations were pushing out all down the sides of the stock below the grafts. We do not remember whether the stem variegations were of the same varieties as the stem or the stock, which would be very interesting to know; but we have a note from Mr. J. Stough, which shows that the influence downwards does carry with it the identity of the graft. He has a Mountain Ash on which is grafted, 3 feet from the ground, a Bartlett Pear; last year, 6 inches below the graft, a Pear sprout came out which is now 7 inches long, and there are Mountain Ash sprouts above and below this Pear sprout. Mr. Stough takes great pride in preserving this curiosity, as well he may. He informs us that he once had a Rose Acacia (Robinia hispida), grafted on the Black Locust (R. pseud-acacia), which pushed out Rose Acacia sprouts from the stem which tried to bear Rose Acacia flowers, in every respect the shoots being as the grafts above it.

These are all very interesting facts, and have considerable bearing on the influence of the graft on the stock.—(*American Gardener's Monthly.*)

WOODSEAT,

The Residence of Colin M. Campbell, Esq.

Woodseat is situated on a gentle eminence near the confluence of the Dove and the Churnet on the eastern boundary of Staffordshire, about four miles north of Uttoxeter, and half a mile from the Rocester station on the Churnet Valley Railway.

The mansion, built in the Italian style of architecture, is a structure of considerable pretensions, and is surrounded by picturesque scenery. The interior is elaborately decorated, and possesses every advantage for domestic comfort and convenience.

The principal entrance is on the north-east side of the mansion. The carriage-drive passes between sloping banks of diversified outline, but properly speaking, I believe, through a deep cutting, though very natural in its appearance; and large clumps of choice evergreens are judiciously arranged on each side. It terminates in a large open courtyard, encircled with a low panelled brick wall, surmounted by ornamental masonry.

The exotic fernery is situated at the north-east corner of the mansion, and communicates with the billiard and other rooms.

It is like a huge cavity hewn out of a solid rock. The walls are formed of a kind of rugged stone adapted for rockwork, called tufa, brought from Matlock, in Derbyshire. This is a loose and porous kind of stone, formed by depositions from springs usually calcareous, but becoming harder on being exposed to the air. In the arrangement of this house a natural appearance has been successfully combined with effect—here bold pieces of rock clothed with Lycopods or Ferns jut out; there we find a recess overshadowed with the fronds of various Ferns; and in another place the projecting rock forms an arch, from beneath which gushes a stream of water that makes its exit by a subterranean passage. Among the Ferns which find a congenial abode among the crevices of the rockwork, and in nooks overhung by higher portions of rock, may be mentioned Neottopteris vulgaris, or the Bird's-nest Fern; Asplenium Veitchii, a plant of exquisite beauty; A. cicutarium, Didymochlæna truncatula, Adiantum formosum, Lastrea decomposita, Davallia dissecta, D. canariensis, or the Hare's-foot Fern, &c. Associated with the Ferns are a few other plants which naturally delight in the same situation, such as Ficus repens trailing over the stones, and creeping by the side of the rocky streamlet; Dioscorea discolor, Selaginella Wildenovii, S. flexuosa, S. cæsia, Calla æthiopica, and a few other ornamental plants with fine foliage.

The conservatory is at the south-west corner of the mansion, and is in communication with the dining-room, and other apartments. It forms a triangle, two sides of which are 36 feet in length, and it is 20 feet wide at the base. In the borders there was a fine collection of vigorous Camellias, with luxuriant dark green foliage, some in bloom, and others just bursting into flower. I also noticed Epacrises, Monochætum ensiferum, and a large stock of Linum trigynum, covered with a mass of bloom. It would be instructive to the readers of this Journal if Mr. Rawbone, the head gardener, would record in its pages the mode of treatment by which he flowers the plant in such perfection at midwinter. The gorgeous Camellias in the background, and the Linums, interspersed with Poinsettias and other gay-flowering plants, rendered the conservatory as brilliant at the time of my visit (December 20th), as other conservatories generally are in summer.

There is a range of houses near the conservatory, and on proceeding from the latter, the first is a greenhouse 30 feet long by 18 feet wide, well filled with healthy plants of Eriostemons, Polygalas, the much-neglected yet beautiful Correas, and huge plants of Azaleas, 6 to 8 feet high, trained in the pyramidal form with the utmost exactness. Among the sorts cultivated were Sir H. Havelock, Chelsoni, Criterion, Brilliant, Imperialis, Virginalis, Le Lion de Flandres, President, and Amœna, the last the most useful of all for early forcing purposes.

The second house is the early vinery, which had been just started; the wood was in excellent condition. It is 31 feet long by 17 feet wide, and is planted with Black Hamburgh, Buckland Sweetwater, and Golden Hamburgh.

We next enter the Peach-house, 40 feet long and 17 feet wide. The trees are trained under the roof to two trellises, one row of dwarfs in the front, and a row of standards behind. In the cultivation of the Peach and Nectarine, as well as of the Vine, Mr. Rawbone seems to develope no ordinary amount of skill. It was partly from this house and the early vinery, that the collection of fruit came which took the first prize at the Royal Botanic Society's Show last July. A superficial observer might almost mistake the Peach trees for Lord Suffield Apple trees, the short-jointed sturdy wood, and the bold prominent buds with which the trees were covered, more resembled those of the Apple tree than of the ordinary Peach. The borders, which are 3½ feet deep, rest upon 2 feet of drainage. Mr. Rawbone uses a rather adhesive soil—a very strong turf—with not a particle of manure, a quantity of rough lime rubbish being intermixed with it, and the whole very firmly trodden down. Last autumn he had occasion to root-prune two young trees that were growing too luxuriantly, and so firm was the border, that he was obliged to use a pick to remove the soil from about the roots.

The last house in the range is a late vinery of the same dimensions as the first, and the varieties grown were Lady Downe's, Alicante (Meredith's variety), White Tokay, Muscat of Alexandria, Trebbiano, and Black Hamburgh. There is one set of Vines planted in front, another along the middle of the house, trained to the pillars that support the roof, and a third against the back wall. The last during the past season bore fruit within a few inches of the ground. When I saw the Vines the fruit was all gathered, and notwithstanding the fine fruit and heavy bunches that had been grown during the last season, they promised to do equally well in future. I can give no conception of the strength and size of the Vines, though they have only been planted three years. With fruit from them Mr. Rawbone took the first prize for Trebbiano and Alicante, and the second for Muscats, at Liverpool, in the autumn of 1865, and last November he also took the first prize for Alicante, and a like award for Trebbiano, at the same place. The two bunches of Black Alicante weighed 9 lbs., and the two bunches of Trebbiano 11½ lbs. The latter were said to be the finest Grapes ever exhibited at Liverpool.

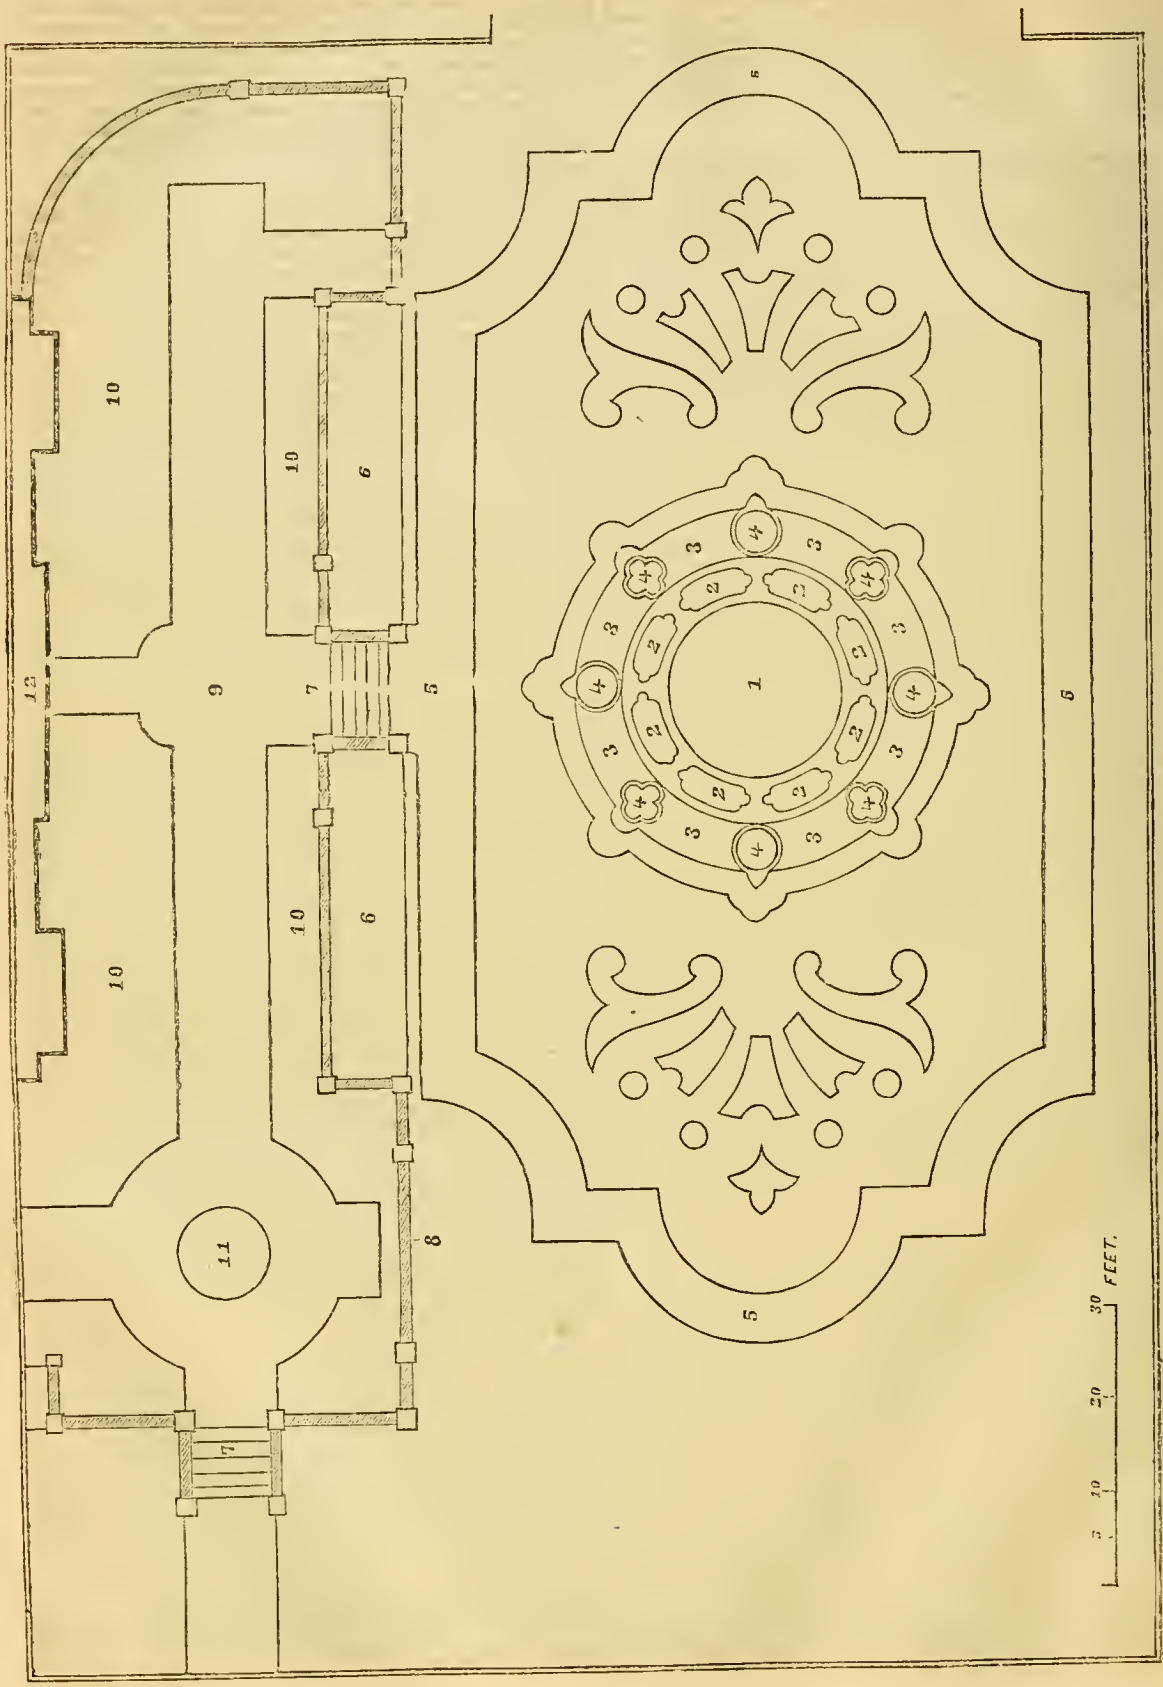
As there has been such a prolonged contest in these pages as to the formation of Vine-borders, I will state the manner in which those at Woodseat are formed. If I remember aright, the borders are raised considerably above the general level. There is in the first place a depth of 2 feet of drainage, consisting of broken bricks and rough lime rubbish left quite open, with drain-pipes underneath, and the bottom concreted. The surface of this lower stratum of drainage is also concreted, and drain-pipes are laid on the concrete, on this another foot of rough mortar rubbish, and then the border, 3½ feet deep, composed of turf thinly pared from an old pasture, a little horse-manure, and a good proportion of old plaster, brick rubbish, and broken bones. The borders are 17 feet wide inside, and 8 feet wide on the outside. Seven feet in width of the inside border is devoted to the Vines on the back wall, and the remaining 10 feet to those planted in the front. Mr. Rawbone practises the bit-by-bit system of border-making, which is so frequently recommended in this Journal. The inside borders were made first, and the roots had well filled and permeated the whole of the inside mass before the outside borders were added. The same attention has been paid to drainage on the outside as within. The outside border is 6 inches lower at the back than the inside border, and gradually slopes towards the front.

The next house we enter, for Pines and stove plants, is 50 feet long and 17 wide, with a narrow path along the centre. The front part is entirely devoted to Pines, some just pushing into fruit, and others for succession. They looked remarkably healthy, and were particularly distinguished for thick, sturdy, compact foliage, rather than lanky leaves, many not being more than 2 feet long. The back part of the house was filled with stove plants, fine examples of health and vigour. Among the most conspicuous were Sphærogyne latifolia, a very beautiful specimen; Cyperus alternifolius variegatus; Rivina humilis, covered with a profusion of crimson berries, a most useful plant during winter for dinner-table decoration and for conservatory embellishment; Dipladenia amabilis; Bougainvillæa glabra; Eucharis amazonica, smothered with masses of pure white blossoms; Begonia carnea, a well-known favourite; Ixora javanica, very fine; I. acuminata, I. salicifolia, Dracæna ferrea, D. Cooperi, and D. terminalis, intermixed with huge Crotons of various sorts, Alocasias, Thyrsacanthus rutilans, &c. On the roof was trained a plant of Thunbergia Harrisii, gaily covered with purple flowers, a very useful stove climber.

In front of the house just referred to was another pit of the same length, full to overflowing with many kinds of plants for spring and summer decoration, besides other pits devoted to Cinerarias, Primulas, herbaceous Calceolarias, and thousands of bedding plants, all arranged so as to effect the utmost economy as regards space.

At the back of the vineries is a Mushroom-house heated from the same medium as the vineries, in which Mushrooms are grown by the bushel. Mr. Rawbone told me that he found Cutbush's Milltrack Mushroom spawn to run the quickest and yield the heaviest crops.

We have now traversed most of the houses, and returning towards the terrace front of the mansion, I will take the reader along several of the walks of the pleasure grounds; and though my visit took place in midwinter, when deciduous trees were stripped of their foliage, and vegetation generally presented but a cheerless aspect, yet in my rambles I made many notes of general interest. The terrace front faces the south-east, and commands many interesting views. The mansion is a little elevated, and the park slopes gently to the railway, which is skirted by a belt of Scotch Firs and other trees of the Pine tribe. Through the vale run the rivers Churnet and Dove, and a little farther on the former terminates its course and joins the Dove; on their banks graze many sheep and cattle, which give interest to the landscape. On the opposite side of the valley is a long range of hills, called Heaton Woods, their summits almost enveloped in the clouds, and covered with



FLOWER GARDEN AT WOODSEAT.

wood and heath. To the right lies Needwood Forest, a vast tract of land, which up to the commencement of the present century was in a state of nature and a favourite hunting ground. The terrace is encircled with a low balustrading; and below the terrace, directly opposite the mansion, is a neat flower garden, of which the accompanying is a plan, laid out with much taste.

REFERENCES TO PLAN.

1. Grass, surrounded by a kerb of stone, a vase in the centre.
2. Beds edged with Box on gravel walk.
3. Beds edged with Box.
4. Beds with a broad stone kerbing. The other beds at each end are cut out in the turf.
5. Gravel walk.
6. Grass slopes.
7. Ornamental stone steps.
8. Balustrading. The squares indicate positions for vases to be filled with Pelargoniums, &c., in summer.
9. Gravel walk on terrace.
10. Grass.
11. Sun dial.
12. Mansion.

In the front of the conservatory is the croquet ground, and near this spot is a fine old Cedar of Lebanon, which has withstood the storms of many a winter, and now stands venerable in its old age. Wending our way to the left we come to a rustic summer-house, from the doorway of which may be obtained pleasant views of the lake and its numerous waterfowl. I saw it when the sun was shining through the hazy clouds, and its waters glittered like burnished silver, whilst other beauties distant and near offered themselves in turn to my eye, and united to form a scene of unrivalled interest.

Pursuing my course downwards I came into a romantic rocky dell, called the rockery and hardy fernery. Its position is sufficiently secluded, and it affords that amount of shade and dampness which the plants grown there require. It is formed of a quantity of picturesque old roots, gnarled and contorted stumps of trees, and oddly shaped stones skilfully disposed to produce effect; and from the artificial rocks little streams of water occasionally trickle. All the plants in this little dell seemed quite at home, and those of trailing habit scrambled about in the wildest confusion and luxuriance. Among the numerous plants growing in this locality I noticed as the most prominent Escallonia rubra, Kerria japonica, Euonymus variegatus, Berberis Fortuni, Yucca gloriosa, and Skimmia japonica, a very useful plant in winter either for in or out-door decoration. The beautiful berries, with which it is densely covered, render it valuable also for the embellishment of the dinner table. It is easily propagated by the seeds the berries contain. There were in addition Polystichum lobatum, Polypodium vulgare, P. dryopteris, Lastrea Filix-mas, Scolopendrium vulgare, Thujopsis borealis, on inverted old tree roots, Berberis Darwinii, and Sciadopitys verticillata, or the Umbrella Pine, intermingled with variegated Ivy, Cotoneasters, Pernettyas, tufts of Sedums, and the Green Spleenwort (Asplenium viride), brought from Croxton Abbey. I passed from this secluded spot beneath a rustic arch covered with Honeysuckles, Clematises, &c.

The pleasure-grounds present quite an undulating surface, and are ornamented with clumps of choice evergreens, and specimens of Conifers disposed in the highest style of the landscape gardener's art, and possess a charm of no mean order when the destructive ice-king has thrown prostrate the beauties of the floral world. Among the most noticeable plants were vigorous specimens of Thuja Lobbi, Picea Nordmanniana, Picea nobilis, Cupressus Lawsoniana, Wellingtonia gigantea, and different species of Juniperus, Taxus, Pinus, &c. Andromedas, Kalmias, Rhododendron ferrugineum, Berberis of sorts, Cotoneasters, and the stronger-growing Rhododendrons, are massed in quantities sufficient to produce effect, and to develope the habits and characters of the different plants. A narrow stream of water runs through the lower part of the grounds, and on its banks and in the water were growing many aquatic plants.

Arriving at a bridge, which I passed over in going towards the kitchen garden, I caught a glimpse of a long strip of ground that skirts the pleasure-ground, and which, during the summer, is planted in the ribbon style. Mr. Rawbone told me that last season he planted it as follows, and the effect was very good. Beginning at the front, the first row was Cerastium tomentosum; second, Lobelia speciosa; third, Pelargonium Brilliant; fourth, Calceolaria Aurea floribunda; fifth, Pelargonium Christiue; sixth, Stella Nosegay Pelargonium; seventh, Gladiolus.

The enclosed kitchen garden is about an acre in extent. On the walls were well-trained Peaches, Apricots, Pears, Plums, and Cherries, and round the different quarters were good examples of pyramidal Apple and Pear trees. This system of fruit cultivation is now becoming very popular, and deservedly so too, for it has been demonstrated that a great variety of fruit, and of excellent quality, can be thus obtained from a limited plot of ground. Fine beds of Strawberries with their crowns prominent were conspicuous. Many of the newer kinds were grown in the nursery plantations to test their suitability to the soil and climate previous to planting them in the permanent beds.

I have dwelt longer on the gardens of Woodseat than I contemplated; but I may say, in conclusion, that the last place I visited, but not the least interesting, was the gardener's cottage. It was, for size, convenience, and accommodation, what all intelligent and respectable gardeners ought to enjoy, and offered a marked contrast to the inconvenient back sheds, unhealthy rooms over stables, and low, damp dwellings, into which gardeners are too often thrust. The walls were mantled with Roses and other climbing plants, and in front of the cottage was a neat flower garden. I received an unlooked-for amount of courtesy from Mr. Rawbone, and I have only to add, out of no mere compliment, that the place was in excellent keeping, and that progress was everywhere apparent.—Quintin Read.

NOTES AND GLEANINGS.

Dr. Seemann, who has recently returned from Central America, has, we are informed, brought with him a large collection of novelties from the Chontales gold region, some of which are said to be of a very ornamental character.

—— To form alum crystallisations over fresh flowers, make baskets of pliable copper wire, directs the American "Journal of Pharmacy," and wrap them with gauze. Into these tie to the bottom Violets, Ferns, Pelargonium leaves, Chrysanthemums—in fact, any flowers except full-blown Roses—and sink them in a solution of alum of 1 lb. to the gallon of water, after the solution has cooled, as the colours will then be preserved in their original beauty, and the crystallised alum will hold faster than when from a hot solution. When you have a light covering of distinct crystals that cover completely the articles, remove carefully, and allow them to drain for twelve hours. These baskets make a beautiful parlour ornament, and for a long time preserve the freshness of the flowers.

—— A gardener of Ghent has, after many trials, succeeded, writes *Galignani*, in giving any kind of fruit the flavour he pleases while it is still on the tree. Let us take an Apple for instance; he pricks it rather deeply in four or five places with a large needle, and then lets it dip for a while in a bowl containing a liquid possessing the flavour he wishes to communicate. After a few seconds this liquid will have penetrated into the pulp; and this operation being repeated two or three times, at intervals of eight or ten days, the Apple is left to ripen on the tree, and will subsequently be found to have acquired the taste either of Strawberry, Raspberry, Cloves, &c., according to the liquid employed.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Broccoli, plant out, also *Cauliflowers*, and water the late Cauliflowers most abundantly. Sow, also, on a rich border, so that they may be thinned out to attain perfection without transplanting. Sow *Cabbages* for planting out for Coleworts. *Carrots*, sow another bed of Horn. *Endive*, those who desire a good and constant supply for the autumn and winter, must make a full sowing forthwith. Endive is generally sown too thickly. Another good sowing should be made in the first week of July, and a third towards the middle of the same month, after which the plants will not attain their full size. As soon as the plants are a few inches high, mow the tops of the leaves off with a scythe, cutting about one-third of the leaves away. This will stiffen the plants and cause much heart to develope itself, as well as enable them to bear transplanting better. *Celery*, plant; and completely remove all suckers. *Leeks*, prepare the ground by heavy dressings of manure. *Mushrooms*, the spawn should now be made without delay. *Peas*, the last sowing of Knight's Marrows should be made. Some of the earlier kinds should also be sown. *Lettuce*, sow thinly in rows 1 foot apart, and transplant from seed-beds before the plants become too large. *Savoys* and *Brussels Sprouts*, plant.

Turnips, this is a good time for a liberal sowing of autumn Turnips, the Dutch or Stone is best for the kitchen garden.

FRUIT GARDEN.

The ground having acquired its usual summer warmth, with abundance of moisture, wall trees are making rapid growth, and prompt attention must accordingly be paid to their regulation. The foreright shoots of Pear trees will require to have their points cut or clipped off, but do not cut their points back to the extent usually practised. Two or three inches off their points will generally be sufficient, and if the shoots appear crowded in places they may be thinned by cutting some out close to the base, and others to about 3 inches from it. If any shoots are overtopping the wall they should be reduced in the first instance. The fruit of Peach and Nectarine trees should be finally thinned. Laterals must be stopped above the second bud. Advantage should be taken of moist weather to remove the clay from grafts where the growth of the scion requires the matting to be loosened, but this must at all events be attended to before there is danger of the scion being galled by the ligature, which will be the case in proportion to the quantity of the foliage that the shoot has made. Layer Strawberry-runners in small pots for forcing.

FLOWER GARDEN.

All recently-planted beds should be regularly watered, observing to stir the surface as soon as it again becomes a little dry, to keep the earth moist beneath and to prevent the ground from cracking. Rockets, Phloxes, and other herbaceous plants now coming into bloom should also be watered if the weather continues hot and dry. Dahlias would be greatly improved by a slight mulching of rotten dung during very hot or dry weather. Do not mow grass lawns too frequently if the weather continues hot, but ply the Daisy-rake during the heat of the day. Gentian edgings should be regularly attended to with water, nothing injures this beautiful plant so much as drought. Seedling Auriculas which have been pricked out in store pans must be protected from drenching rains, at the same time taking care that they do not suffer from extreme drought. Occasionally look over old plants, keep them free from weeds, and carefully notice whether the drainage is free. No plant suffers so soon as the Auricula from deficiencies in this respect. Shade Ranunculuses from intense heat where it is desired to prolong the bloom, or where the flowers are to be exhibited. Flowers intended for cross-breeding ought not to be shaded. Pinks are in various localities unusually late this season, but are now making rapid progress. Tie-up the buds with waxed thread, retaining only one or two on weak plants. Pipings may now be put in. The most successful mode of propagation is to prepare a border on the north side of a wall or fence, to dig it one spit deep, to rake the surface fine, and to cover it about 4 inches deep with about a barrowful of light sandy soil; then water with a fine-rosed watering-pot. Instead of cutting off the piping at the third or fourth joint, it is pulled out of its socket, and, being held between the finger and thumb, it is pushed into the soil. Not a blade of grass should be cut, and no knife ought to be used in the operation. In a month or five weeks the pipings will be struck and fit to plant out in beds in showery weather. Pipings of Carnations and Picotees will strike freely if treated in a similar manner.

GREENHOUSE AND CONSERVATORY.

The conservatory being thoroughly relieved of all superfluous stock, nothing remains but to carry out a cleanly system of cultivation, and to introduce fine specimens from other houses or pits. All available surfaces should be moistened with water morning and evening, thorough ventilation afforded, and a thin canvas screen kept on during bright sunshine. In the mixed greenhouse use abundance of water morning and evening, with a free circulation of air. Camellia stocks may now be grafted, choosing the young wood which has the leaves perfectly developed, and which is of a ripening brown colour at the base. We use the bottle plan, and find it answer well if the plants receive close or cutting treatment for a month afterwards. A slight hotbed with a bottom heat from fresh fermenting matter (to yield much steam), of 80°, will do well, placing a foot deep of cinder ashes over the bed to keep down the worms. Remove all young Heaths into frames or pits; if to frames, make them face the north, when little shading will be required. Place the plants on a bottom of coal ashes, and supply them liberally with water. As many of the specimens which flower freely are apt to go off without giving warning, pay particular attention in watering, that the ball is quite moistened through. This tribe of plants suffers more just now from want of an abundant supply of moisture than from all other causes combined. Many of the plants also, from long confinement under glass, when succeeded by hot and dry weather, suffer extensively from mildew. When this is perceived sulphur them well, and place them in the open air under a wall, or better, behind a hedge in a north aspect. In a few days the sulphur may be syringed off, first laying the pot on its side, and then plying the syringe in all directions.

STOVE.

This will now be a good time to increase many of the valuable sorts of stove plants, they being now in a free-growing state. Take off short and rather firm shoots, plant them in sand in bottom heat under a hand-glass, and most of them will strike root in a few days. The Luculia, of which so much has been written, will root with certainty and freedom. The main point is to catch the wood in a proper state; select short young shoots, and the difficulty of propagating it ends. A very free use of the syringe, with abundance of air night and day, should be persisted in, the main business being to produce sturdy plants with short-jointed wood. Liquid manure, composed of cow-house drainage, guano, and soot water, should be constantly in use, taking care to apply it in no other way than clear and weak. Give air most liberally to Orchids, syringing them freely early in the morning, and shutting up much solar heat, together with wet floors, walls, &c.

PITS AND FRAMES.

All late-struck cuttings, if not wanted for turning out, should be potted off for store plants, or for filling beds in the autumn. Continue to shift any plants that require it. A little air should be given during the night, if the weather continues hot, to prevent plants from becoming drawn. Shade during the heat of the day, and water freely.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Though still very busy in all departments we are beginning to have the prospect of mastering the work. No weather has been more suitable, from its sunshine and showers, for encouraging weeds, as well as more useful growths, and the hoe has been unsparingly used at every favourable opportunity among growing crops.

Walks which a month ago were, as respects cleanliness, everything that could be desired, have again demanded attention. A broad smooth walk was becoming green at the sides, robbing the fresh growth of the Box-edging of its beauty, and after a shower the sides were hoed, raked, to be followed by a rolling, when the small weeds have been withered out of sight, for picking them up would have been a serious affair. The centre or main point of the walk being clean was left untouched. Had the verges been tiles or slates we might have ventured on a little salt, but we never like to put salt nearer to Box-edgings than 12 or 15 inches. The central part of the walk was too fine and smooth to permit of salting to advantage, even if it had needed it, as the salting would always have a tendency to make the surface smoother, and then in wet damp weather it would increase the tendency to rise and clag with the boots. Another side walk was becoming rather green, conspicuously so when the small weeds were glistening with the dew, but as this had a rough pebbly surface we merely hoed and raked the sides, and salted the centre, as that will make short work of the weeds there, and if the salt does crack and lessen the size of the pebbles in the gravel, it will make it all the more pleasant and agreeable to walk upon.

We are particular on this matter, because several inquiries have been made as to the circumstances under which it is advisable to salt walks, and we have half a dozen complaints that firm smooth walks have been rendered unfit for walking upon after salting whenever the weather was damp. "Ango" tells us he has a broad smooth walk becoming completely green, and he dreads breaking it up, and wants to know how to clean it, unless by a layer of salt. We would advise scraping off the surface if that can be done, and adding a sprinkling of sandy fine gravel. The quickest way would be to salt it all over, and on the salt place a good sprinkling of fine sandy gravel. The fresh gravel will become partly saturated with the salt, and the surface will yet be so free from it that there will be no sticking to the feet in damp weather. To heavily salt a smooth walk without such a surfacing is almost to make sure of a soft walk all the winter. Salt, therefore, we consider the cheapest and quickest way of freeing walks from weeds; but our experience

forces us to add that it is anything but economical when the wear of gravel and the subsequent comfort of walking on it in all weathers are concerned. This is more especially the case when chalk forms any part of the gravel.

When court-yards are pitched with large hard stones, or still more neatly with hard pebbles, from half to the full size of a fist, and on which the wasting agency of salt acts little or nothing, there is no means of cleaning such places equal to salt, either scattered over it on a sunny day and the dews allowed to melt it, or the salt mixed with hot water close on the boiling point and applied at once. We think scattering the dry salt thickly enough just to make a white sprinkling is as effectual as any, if the salt will remain a day or two without being all dissolved. If a sudden shower follows after the application, it will be less effectual. The scattering of the salt is, therefore, most effectual when applied in dry weather, and the whitish appearance is little thought about as unpleasant. The salt when dissolved in hot water acts at once. It is best, however, kept from edgings of all sorts, as it will injure Box, as well as weeds, and even stone and tile edgings, if at all soft, will crumble and waste from its use. Mr. Fleming used it at Trentham, in small parterres, and even among the letters of the names of some of the family formed with Box, but we cannot say that we have used it much close to Box edgings, without seeing its deleterious effects.

Potatoes.—A gardener in a large place has informed us that a part of a pit of his Potatoes went off just as we described last week, the underground stem becoming rotten a little below the surface of the ground, whilst earlier and later varieties under similar circumstances were not affected. In his case, as if to show there was nothing in the soil, he pulled out all such Potatoes, and planted again, and the second crop was growing quite healthily. This is the only other case of which as yet we have heard, and it seems to throw no light on the cause or reason of the failure. In our case, we never had a crop that looked better before the disease manifested itself.

Seeds.—All sowings must be secured from birds, and covering the seeds with red lead just damp enough to encrust them, is a good protection. A net is also useful, as there are many plants of which birds are fond just as they are in, and a little beyond the seed-leaf. As to Peas and Beans, we found the red lead also effectual, and even mice scarcely touched them, but for pheasants and partridges we find the cheap galvanised wire netting advertised every week, of two-inch mesh, quite a sufficient protection. We merely bend the wire in semicircular form over the row, and put in a few sticks along the sides to fasten it to the ground, and remove and roll it up when the Peas are 3 inches in height. The pheasants can put their heads easily through the meshes, and withdraw them without injuring themselves, and without being able to reach the Peas.

Cauliflowers that were coming on rather fast were pulled up and placed in a wide barrel with a little water at the bottom.

Peas.—All have been cleared from the orchard-house, as the outside ones have been coming in freely. Cauliflowers and Cabbages will now be benefited by all the manure water that we can give them. Cottagers in general are not yet aware how largely they may increase their crops by a free use of all the slops and sewage from their houses, &c. A man of thought will contrive some receptacle in his garden, at the farthest possible distance from his house, where he can always put his hand on a number of pailfuls of such valuable manure. The precaution we must add is—use it as often as you like, but not over-strong.

Cabbages.—Merely for the sake of the amateur, who may have little room and wishes to make the most of it, we would speak in high favour of Messrs. Veitch & Sons' improvement on Atkins's Matchless Cabbage. We have just now a little piece fit for table; compact heads, firm, and becoming white inside, and on actually measuring the plants we find they range from 11 to 12 inches in height from the surface of the ground, the plants having had no earthing-up, whilst the diameter of the plants, from outside to outside of the large bottom leaves, was not more than 12 inches. This kind, therefore, could be grown in the greatest perfection in rows 15 or 16 inches apart, and 1 foot apart in the row. We measured fine specimens of larger Cabbages beside them, with larger heads it is true; but the diameter of the plants, as regarded the lower leaves, was from 27 to 30 inches. The cabbaging central part is the great object; the huge outside leaves make little appearance on the table, and hence we speak favourably of this compact Cabbage, which is quite in the style of Atkins's Matchless, which we grew for many years; but it is still more compact and upright in growth, and has, so far as we see this year, fewer and smaller side leaves.

Sowing, planting, &c., much the same as in last and previous weeks. Pricking-out winter stuff, as every yard of ground is already occupied, and will transplant when there is more room. We lost every Kidney Bean out of doors by the frost, and not one of them came or broke again, as they have done in many places. Garden Beans were scarcely injured—not so much as Peas, and those transplanted are coming in well.

FRUIT DEPARTMENT.

Gathered the first dish of Black Prince Strawberry out of doors on the 14th of the month, and picked a few Keens' Seedling. Keens' Seedling in the orchard-house has done very well, and is yielding profusely. British Queens in full bloom in the coldest orchard-house during the severe May frosts have not set so well. We feared at the time the bloom was injured. For a standard that will bear all sorts of rough treatment, there is no Strawberry with which we are acquainted that will compete with Keens' even now, though many of the newer kinds are very good, and bear well too; but it is rare for Keens' to fail under even adverse circumstances. Thinned pretty well finally the crops in the first orchard-house, though we fear we have still left too many, and we must commence with the later house immediately, as the fruit is still far too thick. Cherries have ripened well, and come in useful, and it will be as well to have them over before they come in out of doors. We saw on Saturday a few shoots of Peaches which had been attacked by our old enemy the Aphis persicæ, and we quietly slipped them off and took them carefully to the nearest furnace, and gave the house, except the Cherries, a good lashing with clear soot water. Out of doors the changes of the weather have brought fly, green and black, on Plums and Cherries, and after a rough handling to remove the worst, gave the trees a hard syringing and engining with clear lime water and clear soot water, which seems to have settled the most of them. Will go over them with a brush and clear quassia water as soon as we can.

ORNAMENTAL DEPARTMENT.

Proceeded with our bedding-out, though there will yet be much to do with carpeting and edging-finishing. Dahlias will now be perfectly safe, and it was as well to wait a little in such weather. Tulips and other bulbs may be lifted as the foliage decays. Pinks and Carnations and Picotees want supporting carefully. There is no support neater and more economical than twisted wire, about the thickness of a quill, 6 inches or so straight to go in the ground, the part above twisted in half volutes, so as to leave an open space when looked down through the centre. Fifteen inches would do for most Pinks, and from 30 inches for Anne Boleyn Pinks, Carnations, and Picotees. No tying is required. You merely place the flowering-stems as they grow round the twist, and that holds them securely. A set of such wires, if kept painted, would last for many years. The quickest way to paint them is to place the paint on a glove on the left hand, and then draw the wire regularly through it and quickly. If the wires galvanised they need no painting. The Messrs. England, wire-workers, of Hertford, used to make them in large quantities. No one after using them would ever be troubled with cutting sticks and tying the shoots to them. There is a broader whorl at the top for the flower to rest on. We used them largely at one time; but, alas! the rabbits did for that pleasant work, and if we obtain a good collection again of these fine, old-fashioned flowers, we must keep them inside of walls.

In moving plants from the houses, conservatory, &c., for the summer season, great care must be taken that they receive no sudden check, and especial care must be exercised that the pots are not exposed to a burning sun. See the directions given by Mr. Keane, as to Heaths, Epacrises, Primulas, &c.

We will finish this busy week with a few words on *sowing small seeds*, such as those of Calceolarias, Primulas, and Cinerarias, at this season, to meet the case of a few correspondents who tell us that year after year they sow, and are no further forward, as they hardly ever obtain a plant, though purchasing the seed from the best seedsmen. We have seen pots sown with no better success, and from the same packet we have sown and had a carpet of seedlings. We believe in the great majority of cases, the want of success is owing to some fault in the watering; either the seeds when germinating are starved with dryness, or they are deluged, or washed out of the pots, and perish then from exposure to sun, &c. We would recommend for all small seeds, not so much for Primulas as for Calceolarias, Lobelias, &c., little or no watering until the seedlings appear, and then let moisture be given as much as possible

from beneath, instead of from above. To be precise, choose pans or pots for sowing in—say the latter, for convenience, and suppose they are six-inch pots, fill them nearly half full with drainage, then a layer of rough riddlings, then another layer of finer soil—say sandy loam, and a little peat, pressed well down, and a third layer of finer still; but to terminate within one inch of the top of the rim of the pot. Press all firmly down with a round board, with a nail or a wooden peg in the centre for a handle. Then water all these thoroughly, either through a fine rose, or by setting the pots in a tub of clean water, so that the water will cover them all over. When soaked lift the pots out carefully, and allow them to stand in a shady place for from twelve to twenty-four hours, until they are thoroughly drained, and the surface soil is just becoming somewhat dry. On this sow the seeds. Scatter on them, if very small, the least sprinkling of dry sand, and press with the board, or the bottom of a pot gently. Plunge the pots, but not too closely together, in ashes in a frame, or under a hand-light. Place a square of glass, or a piece of stout paper over each pot, if glass, which is best, cover it with paper, or a little moss, until the seedlings appear. If notwithstanding this care the surface soil become rather dry before the seedlings appear, pour water among the ashes in which the pots are plunged, and that will generally be sufficient. If in some extreme cases that does not afford moisture enough for some particular small seeds, either sail the surface of the soil carefully with water, or what is better and safer, lift the pot carefully out, and holding it in your hands place it in a pail of water, so that the surface shall have water placed gently all over it without the chance of displacing a seed.

With such care as above detailed—all very pleasant work for amateurs—the little seedlings will soon coma in general, and as soon as they manifest themselves the shading of paper, &c., must be removed by degrees—first at night, then morning and afternoon, and then altogether; and air should be given also gradually—first raising the square of glass at a corner, increasing it by degrees, taking it away at night, replacing with this raising up during the day, and finally removing it altogether, leaving only the top of the hand-light on the frame, and giving more air by degrees by this outer covering. This may be all done in a common window-sill. A thin paper frame makes an excellent substitute for a hand-light, and a double pot with moss between the inside and outside pot makes a fine substitute for a bed of ashes. Bear in mind that until the seedlings of these small seeds are pricked off separately, or in little patches at first, it will be more or less unsafe to water a thicket of seedlings overhead with the finest rose. It will be safer every way to cover the surface with water by pouring it carefully on a potsherd at the sides, or setting the pot, held by the hand, in a pail of water until the water gently trickles over the rim and covers the surface. If the outsides of the pots be kept moist, these operations will seldom be necessary, and this object can be effected as well by a double pot as by plunging in a bed. With such precautions there will be fewer complaints of want of success, and less blame laid at the doors of the best and the most honourable seedsmen.—R. F.

COVENT GARDEN MARKET.—June 19.

Heavy supplies from some parts of the Continent have had considerable influence here, and prices recede The quality of our own produce is well kept up, and contrasts favourably with that of the former, which suffers considerably from packing and the different shifts in transit. The arrivals ceastwise of Potatoes have been large, the chief shipping ports being Lisbon, St. Malo, and those of the Channel Islands, best samples maintaining their previous rates—viz., 3d. to 4d. per lb.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Orchard-house Management.—A clergyman, "W. W.," wishes that "C. P.," who wrote on this subject at page 393, would send his address to this office, as "W. W." would be glad to have permission to visit "C. P.'s" orchard-house.

Suggestion (*W. Taylor*).—Thanks for your suggestion, but we carried out your idea very fully some years since—and all the subjects you name, Soil, Manures, Light, Heat, &c., were included. The whole have now been collected and published in a volume, entitled "Science and Practice of Gardening," which you can have free by post from our office, if you enclose forty postage stamps with your address.

Depriving Standard Roses of Flowers (*J. P.*) —If the standard Roses are deprived of their flowers now, they will flower again in August. The objection to depriving Roses of their first flowers is, that it delays the ripening of the wood for next year. I advise "J. P." to leave on the centre bud on such wood as he wants for next year, and deprive the branch of the other buds. As soon as the flower drops the branch may be cut back to a good full eye. Roses require different periods to come to maturity of flower. Général Jacqueminot is one of the quickest. Duchesse d'Orleans and Washington are two of the slowest. "J. P." may cut back some of the inferior branches at once. If Roses are deprived of their flowers early in the season, of course, their autumn blooms will be finer. I am not satisfied with less than three series, and continuity of blooming besides. The Roses here (on the Manetti stock), began to bloom abundantly June 8th, and I expect them to continue doing so till winter stops them.—W. F. Radclyffe.

Flower Garden Plans (*A Young Gardener*).—As soon as the work, which is in progress, shall be sufficiently advanced, all necessary particulars will be duly advertised. For obvious reasons it would be premature to make any definite announcement at present; but we may add that it will be published with as little delay as possible.

Arabis lucida variegata and Aucuba-leaved Daisy for Edgings (*Bellis*).—We consider Arabis lucida variegata the most beautiful of all golden-variegated edging plants of compact dwarf growth, and to be preferred to the Golden-leaved Daisy, which is also very handsome. Neither of them can be raised from seed, both are increased by division. The fragment of Fern sent us was Polypodium dryopteris.

Pyrethrum Golden Feather (*Idem*).—The price of this handsome, dwarf, compact-growing plant is from 2*s.* 6*d.* to 3*s.* 6*d.* per plant. It may be obtained from the principal nurserymen.

Fungus on Lawn (*A. S.*).—You may free your lawn of the fungus by applying a dressing to the lawn with salt at the rate of 1 lb. per square yard, or lime water made by pouring thirty gallons of water over a peck of fresh lime, stirring well up, and allowing the liquid to stand for forty-eight hours. Water with the clear liquid, giving a good soaking.

Ventilating an Orchard-house (*A. B.*).—We would decidedly approve of the perforated zinc over the ventilating openings to keep out flies, &c.; but these openings will have to be all the wider in proportion to the spaces of zinc, through which no air can go.

Destroying Ants and Woodlice (*Joseph Stillwell*).—You may drive away the ants by sprinkling guano over their haunts, and you will find a Bantam hen and chickens make quick work of the woodlice. A breed of Partridges turned into your garden would do better with the ants.

Peach-tree Leaves Diseased (*A Subscriber*).—The leaf when it reached us was merely a leathery brown mass. There were some marks as if insects had been present. We incline to think that it is a bad case of blotch and curl, chiefly owing to the unfavourable weather, and, perhaps, also a little, and only a little, attributable to the sulphur and tobacco-water dressings. Cut off all such leaves by degrees, the worst first, and ere long the tree will recover itself and ripen its wood. The more green the wood last autumn, the more likely would the trees be to suffer from this infliction. When leaves are sent in a letter, it is often difficult to detect anything about them.

Select Gooseberries (*E. F. F.*).—Snowball (Adams), white; London, red.

Various (*W. M. G.*).—You may smoke a vinery a week after the Grapes are set. Zinc pots may be used with advantage for growing all kinds of plants. They do well, as proved practically, for Strawberries and all kinds of cuttings. We would prefer Fuchsia fulgens, corymbiflora, and the large-berried kinds, as those to experiment upon for raising berries fit for table. We never knew anybody who liked to do more than taste them.

Constructing a Small Greenhouse (*T. S.*).—We should like to understand you better before advising you, as, if the wall at the bottom of the garden, or that portion which you can use, faces due north, and the garden is only 18 feet wide, then we can hold out no hope of your being able to grow Grapes, or even good greenhouse plants, though such a house would do to keep the more hardy ones in during the winter, and the more hardy bedding plants, and, with the help of your proposed flue, would do admirably for Ferns and Mosses. Such a house might be the height of the wall at back, and for a lean-to, 10 or 12 feet wide and 6 feet in height in front. We would pave the floor, and make the top of the fine a part of the paved floor, and that in the passage near the front. Provided you are not shaded on the east and west, and could come out 20 to 30 feet, you might have a span house from 10 to 13 feet wide, with a path down the centre, and that would suit any purpose. If your proposed building is to be on the south side of the wall, then with a lean-to you can grow anything.

Heating a Greenhouse (*Ignoramus*).—We would prefer plan No. 1 for the specified purpose, because the three-inch pipes will heat sooner on such an emergency as a sudden frost than four-inch pipes. We would, to give you more power, and to diffuse the heat more regularly, alter the flow-pipe, and take it along the front instead of along the back. Thus, we would take the flow from *a* to *d*, then to *c*, *b*, *a*, and return from thence. Were the front of your stage on posts instead of a four-inch wall, we would place the pipes inside of that instead of outside on the pathway. As it is, we would rather make the wall pigeon-holed to let the heat out freely towards the path and the front platform, and have the pipes inside of it, for it may be necessary at times to sulphur the pipes, and if in the pathway a lady's dress is apt to come in contact with them, otherwise they will do where proposed.

Wireworm in Vine Border (*D. M'Nab*).—The best mode with which we are acquainted of clearing ground of wireworm, is to point-in a good dressing of soot, plant a thin crop of Potatoes, and strew the ground with soot so as to make it quite black. Placing Potatoes or Carrots in the soil and examining them frequently is a good plan.

Vine Shoots Mildewed, and Bunches Turning Brown (*J. M. M.*).—The appearances on the Vine, the mildew on the stem of No. 4, and the turning brown and dropping of the lower end of the bunches as they are coming into bloom, are partly owing to the vigour of the Vines and to a close atmosphere—hot at one time, we presume, and cold at another. The blotches on the leaves show the presence of accumulated vapour in a close atmosphere, that vapour becoming hot by the sun before air is given. The remedies in your case are lessening the vigour of mere growth by a drier and warmer atmosphere, and air at all times, even affording a very little at night, unless when it happens to be very cold. We do not discover any mildew on the leaves, but we would wash the stems affected with a paint of soft soap and sulphur. We would cover the heating apparatus with sulphur paint, but taking care that the heating medium is never higher than 160°. We would also paint all open places on the wall with sulphur. These precautions, with more air and a drier atmosphere, we hope will cause all to come right. We had 6*d.* carriage to pay for the box, which please remit in postage stamps.

Names of Plants (*W. Hathaway*).—If you send us specimens with a number attached to each, we will endeavour to identify them. (*Constant Subscriber*).—Pelargonium cucullatum and Mahernia incisa. (*M. B.*).—1 and 2, Cystopteris fragilis; 3, Pteris scaberula. (*T. S.*).—1, Olearia nitida; 2, Celsia betonicæfolia; 3, Thalictrum aquilegifolium. (*E. S.*).—Scleranthus annuus. (*G. B.*).—Thermopsis fabacea. (*C. F.*).—Oncidium altissimum.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 18th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THIS YEAR'S BIRMINGHAM SHOW.

Before the schedule of the Birmingham Show for this year is issued, I am desirous of making one or two suggestions. To do so may be deemed Quixotic, the Committee having on former occasions displayed so enormous an amount of *inertia*, or passive resistance to all outward pressure, and I should, indeed, deem it waste of good paper to attempt persuasion on any of the vital matters which have from time to time been discussed. Still it has appeared to me that whilst dogged enough in some things, they have had a real desire to make the Show more useful and popular, especially amongst buyers, and to details bearing in this direction I shall entirely confine myself.

I confess I am one of those who like the subdivision of the classes into cocks and pairs of hens; but I think, in simple justice to exhibitors, the system of entrance fees should be somewhat modified, seeing that each pen of three birds now takes double the amount of entries and accompanying fees compared with the old plan. This is not fair, and now that exhibitors are compelled to show all cocks singly, I think the rule of requiring a second subscription of one guinea after the first four pens should be in some way modified—how I would scarcely say; but I would suggest a compulsory subscription of 10*s.*, and a uniform entrance fee of 5*s.* per pen, as about the same thing, for the first four pens, and somewhat more in accordance with the present plan of the schedule.

It is also highly desirable that the cocks and hens in each class should be arranged over each other, instead of in one long horizontal line. Last year's arrangement caused much time to be spent in ascertaining the relative merits of a strain in consequence of this. All breeders know that some strains excel in pullets and others in cockerels, and that it is, therefore, highly desirable before buying a cock from any yard to see what kind of hens the same yard produces. I took particular note of the relative numbers and arrangements of the sexes last year, and can say positively, that whilst by arranging the classes as I suggest, both the judging and comparison by purchasers would be much facilitated, no real difficulty would occur.

Thirdly, It is absolutely necessary for the credit of the Show, that during the Saturday previous to its opening all alike should be rigorously excluded. I am aware this is professedly done, but every one knows how constantly and shamelessly the rule is violated, to the benefit of the mere trading dealers and those large breeders who can send their poultry-men, the injury and disgust of the general body of purchasers, and the yearly disgrace of the Committee. I know one Bristol exhibitor who last year penned his own birds, and, doubtless, many others did the same. This of itself is most unfair to others; but the principal evil of this laxity is in connection with the sale department, and leads naturally to the last suggestion I shall make.

That is, that the sale-office should not be opened until twelve o'clock, thereby to place all upon an equal footing, by giving to all a short interval in which to make their selections. The effect of the present system is, as is well known, that for an ordinary purchaser to buy fairly a first-class pen marked at a moderate price is impossible. All the pick of the Show is either snapped up at once by those who have walked round on the previous Saturday and made their selections, and who can, therefore, at once walk into the sale-office, or by those who have confederates on whose judgment they can rely, and also "hunt in couples." The mode of operation is well known to many; but for the sake of the uninitiated, I may just say, that whilst one worthy obtains the best position he can near the office-door as the actual buyer, the other goes round to select the lots, and telegraphs the numbers to his confederate on his fingers, the result in either case being that the best lots go into the possession of dealers whose only object is to sell again at a profit before the general public have a chance.

It may be said, and was said to me by a large practical breeder to whom I was talking the other day, that to delay the opening of the sale-office till twelve o'clock would cause a "regular fight." So far as that goes, it is so very near a fight

now that I cannot see the force of the objection. It would at all events be a fair fight, which is not the case now; and if I am beaten—say by "NEWMARKET," in the scuffle for the first claim to a pen of Game, I should at least know the reason why, and may go up next year with my "big brother" and hope for better luck. I could give some curious instances of the brazen cheating carried on openly under the present system; but my time is as valuable as your space. The matter is self-evident, and I can conceive no other way to stop the evils complained of than that I have suggested.

These hints I throw out simply as practical matters of detail, only trusting that the Committee will repeat this year the addition of Mr. Teebay's name to the list of Judges—a step in the right direction, and which shews that they are not altogether unamenable to reason.—NEMO.

THE COMING SHOW AT BADMINTON.

WILL you permit me to call the attention of your readers to the Poultry Show which will be held at Badminton on August 7th? This is a first show, and therefore far less known than shows which have been held year after year. A few clergymen and others interested in poultry have got up the exhibition of these birds in connection with the Badminton Farmers' Club; and I cannot help thinking, that the name of Badminton being so well known as associated with that of the Duke of Beaufort, many will like to have an opportunity of gratifying their poultry taste, and in addition having a peep at his world-renowned residence. There will be prizes for different varieties of fowls —small, it is true; but then the Show is young and the Stewards careful, and if the Show pay this season doubtless the prizes will be of greater value next year. There are also prizes for Ducks, Geese, and Turkeys; then prizes for Pigeons—viz., for Carriers, Dragons, Powters, Fantails, Turbits, Shortfaced Tumblers, Baldheads, Barbs, Nuns, and Jacobins. I could have wished there had been also a prize for Any other variety, as this would have filled many pens. I trust there will be some arrangement, by vehicles put on for the day, for conveyance from Chippenham and Yate stations; and then I feel sure, the day being favourable, we shall have a happy throng at Badminton.—WILTSHIRE RECTOR.

BRAHMA POOTRAS.

I HAVE heard it asserted of these, that they are the native American Cochin-Chinas or Shanghaes; but as their East Indian and south-eastern Asiatic origin is well known, this is rather too positive and exclusive an assertion. The pea-combed and non-vulture-hocked, are the made Brahmas, and the single-combed and vulture-hocked the true and pure breed in my opinion.

The Malay origin of the pea-combed birds appears to me to have been carefully concealed by most of their breeders, who express surprise and dissent when taxed with the Malay origin of their pea-combed strains. I think that the strains with the pea-combs, and not vulture-hocked, are also more liable to the long Malay necks than the single-combed and vulture-hocked birds are. Of course, the pea-combs could have been produced as easily in India, by the Malay cross, as in America, or in Britain. The brown-marked birds appear to me to be of the primitive colour of Brahmas, and those with the other markings, not brown, to be the made colours and strains. Pea-combed birds, though the favourites, are certainly not the primitive pure strain of these birds, the pea-comb being popular, as making them a distinct sort from the Cochin-Chinas. Unless for this, I think the pea-comb should be considered as nglier, and also a defective Malay cross.

The vulture hocks are, I think, a proper and distinctive mark of the purity and goodness of the breed, as no bad cross could produce them, but only the Cochin or Shanghae cross. I also think the single-combed birds would be found more prolific than the pea-combed.

I think that the term Brahma Pootra would do best for the whole tribe, Cochin-Chinas and Shanghaes included; but all three names are derived from locality, the river Burrampooter or Brahmapootra, which divides India from Assam and Burmah, being the origin of the first name, and they are probably to be found on both sides of this river. The port of Shanghae, in China, it is scarcely necessary to remark, has a large trade, especially with the United States.

The single-combed Brahmas might not incorrectly be termed the Birchen Grey, Birchen Dun, or Mealy Grey Cochins. I think the Malay expression of face is only found in the pea-combed birds, and never in the others. I think, too, that vulture-hocked birds have, as a rule, a longer, heavier, and better leg-feathering. I think that they ought to be the cup birds in either Cochins or Brahmas, and as the pea-combed have been chosen for cup birds of the latter, though the "bastard" breed of Brahmas, perhaps the vulture hocks should have the cups among Cochins; but I should prefer single combs and vulture hocks in both sorts myself, as distinguishing marks, though I may be singular in so doing.

Pea-combed Brahma Pootras may be bred from any Malay cocks put to the single-combed Brahma hens, as well as from the Birchen Grey Malay cocks put to Cochin hens. Brahmas, like all other fowls, must, of course, be judged by the opinions of the best judges, but as an individual, I consider the single-combed and vulture-hocked to be the true, pure, unmixed breed, and the pea-combed to be the mixed strain, which has been produced by crossing with the Malays. The pea-combed birds are also, I think, uglier in the head than the single-combed birds and clumsier, being thicker in the head cross-ways.

The pea-combed Brahmas have only been increased or continued by careful selection, but may have been first produced accidentally in the United States by the Malay cross. All Brahmas would naturally incline to breed back to the single combs, and, perhaps, to vulture hocks too, if left to themselves in breeding, and often these characteristics are still produced when not wanted, and though birds in which they are present are not at all selected for stock. The legs, or shanks, of the pea-combed birds are often rather too long, partaking of the Malay cross.

As to habits the Brahmas appear to me almost exactly to resemble the Cochins. If crossed with the more sterile Dorkings, especially the rather sterile Grey Dorkings, such Brahmas would be less prolific than others, as Malays are more prolific than Dorkings, especially Grey Dorkings, not being so dry as Dorkings in their constitution. Dorkings could not, unless rose-combed, have given the pea-comb at all, and the pea-comb has much more resemblance to the Malay-comb than to the Dorking rose-comb. The Malay cross, likewise, would not at all improve the laying or table qualities of pea-combed Brahmas. Brahmas are said to sit a little less frequently than Cochins, to lay somewhat less, and to be a trifle worse for table, but are much the same. The greyed-colour and pea-combed Malay cross would lay rather worse, I think.

Brahmas, with Cochins and Bantams, are the best breeds for small spaces and confined yards; the Bantams from their small size and being, when red-combed and healthy, such good winter layers, though their eggs are small; and the Brahmas and Cochins from their inferior powers of locomotion. All other sorts require larger runs than these three.

The Malay cross cannot improve pea-combed Brahmas for table, as the Malays are the worst table fowls of all. Some breeders are ignorant that their pea-combed Brahmas came from Malays by crossing. Some freely confess it, and some conceal it.—TREVOR, OTHERWISE NEWMARKET.

DOTTINGS AT SALISBURY.

WITH a tremulous hand I seize, as T. Hood hath it, "the epistolary implements," for it would seem impossible to make "dottings," without treading on the toes of some, or obliging others by treading on their skirts, as our friends in the Sister Isle prefer being treated. However, having been able to spend a too brief hour at Salisbury, it may possibly interest a few if I give my thoughts on some of the birds collected there.

We poultry fanciers all know too well that June is not the month to see our birds in the best trim. A coat that has to be donned every day, wet or dry, even though carefully brushed at night, will show traces of wear, even under the most careful management: what wonder, then, if our pets after three or four months of constant wear, have plumage less brilliant than of yore? The brilliancy of plumage in the majority of the specimens had certainly deteriorated, yet I must confess that there were some very striking exceptions; notably amongst these the first-prize single Game cock exhibited by the Rev. A. G. Brooke, the prize Partridge Cochins of Mr. Stephens, the Polands and Silver-spangled Hamburghs belonging to Mr. Beldon.

But to the catalogue. The aristocratic Spaniards are always treated as amongst the *élite* of our feathered friends by the Bath and West of England Society; exceptionally with the Coloured Dorkings, they were offered three prizes. There were eight entries of the former, eighteen of the latter, as compared to twenty entries of Dark Brahmas for two

prizes; but to this point I will return. The entries of *Spanish* were certainly meagre in numbers, and excepting the Bristol pens, which were easily first and second, I should call them equally so in quality. In the first-prize pen there was already a divorce, the gentleman behaving very badly. Something of the same kind, I presume, had happened to the first-prize *Dorking* pen, Lady Holmesdale's, as the hen alone occupied the pen, and I could not see the cock. The hen, if I mistake not, was one out of the pen with which her ladyship obtained the prize, *par excellence*, at the Clifton Show, in January last. The hen is certainly splendid in build, and, I expect, in weight, but in my eyes, without the pendulous comb that a single-combed Dorking hen ought to have. Several of the Dorking cocks had their fourth and fifth claws some distance up the leg, so high up that as the birds stood erect, they rested only three claws on the ground, the hinder claw being in some cases half an inch from the ground; this I cannot consider any improvement to a Dorking foot. In White Dorkings, Mr. T. P. Edwards lost all chance, as he did also in the White-crested Black Polands, by sending two hens instead of one in each pen. Other exhibitors committed the same error, and a pen in the Buff Cochin class would certainly have been placed, but for a similar mistake.

The *Cochin* classes, especially the Buffs, were better filled than last year, when five entries contested precedence, and three prizes were offered. I liked the Partridge Cochin birds of Mr. Stephens much the best, they were to my fancy among the gems of the Exhibition. The White Cochins have degenerated, or else my mental visions of the past do not agree with the examples shown at Salisbury.

I scanned my own pets, the *Brahma Pootra* classes, somewhat closely. The Dark headed the poll as to numbers, with the exception of the variety class—twenty entries—the Light made twelve more—thirty-two pens, but only eight were in the prize list. Mr. Boyle headed the Dark class with a large, well-coloured and feathered pen, but the cock was very stilty; as a friend remarked to me, you might drive a coach and four between his legs. It appeared to me that the bird was deficient in depth of chest, and this made his legs appear objectionably long. I greatly preferred Mr. J. K. Fowler's second-prize pen. Mr. Fowler had also a pretty pair of chickens unnoticed, the pullet a beautiful bird. Another pair of chickens was shown in this class, that ought to have been amongst the Light Brahmas. These were perfectly white, and but for the pea-comb might have passed well for White Cochins. They would probably have received some notice in their proper class. The Dark class generally I considered weak in leg-feathering; but with this verdict as to the Dark, what shall I say as regards the Light? There was only one pen that I noticed fairly feathered, the colour very nondescript, as the breast of the cock was black, or nearly so, and the back of the hen brownish. This pen was fairly feathered, especially the hen; the other pens were lamentably deficient in this, to me, most important point. Seriously, less trimming of the legs than some of the Game exhibited had endured about their faces, would have rendered the shanks of many birds, even those noticed by the Judges, perfectly bare. The length, too, of some of the shanks in this class, if bare, would have helped to show that our friend, "TREVOR, OTHERWISE NEWMARKET," might be right as to the Malay origin. Again I lift the warning finger against the naked hock, as certain ultimately to develope the naked shank. I write most impartially. I did not exhibit Brahmas, possibly I shall not do so again, until this extreme horror of the covered hock has somewhat moderated; but if the class of Light Brahmas is to be taken at all as a type of those from which the light birds are bred, and be it remembered some of our most successful exhibitors showed, deterioration has thoroughly set in, and the naked hock is rapidly fulfilling my prophecy.

The *Game* classes were well filled, and contained some beautiful specimens, so I thought; but, perhaps, "our Game critic" was there, and I forbear to say more than that the tweezers had been diligently used in many of the pens, and those in which this precaution had been neglected had not the ghost of a chance. I think the Bath and West of England Society has a rule against trimming, too!

Mr. F. Pittis, jun., was first and second in Golden-pencilled *Hamburghs*. Both the cocks had good earlobes; but both, especially the first-prize bird, had stains of white over the red face in patches; this, certainly, is no improvement to the breed. Many of the combs in this class were large and coarse, and not a few earlobes blushed, I presume at my impudence in remarking them. I thought the Spangled birds the best. *Polands* were few, alas! too few; but they were very beautiful. I preferred Mr. Belden's Silvers; nearly every pen was decorated.

Shall I say that I regretted the paucity of entries in the next class —*Malays?* I might certainly have been differently placed; as it was, I thrashed everybody there, only there was nobody to thrash! Both Mr. Cooper, of Limerick, and the Rev. A. G. Brooke showed other birds, and I regret they did not enter their Malays. Bath and West of England folk have stuck to this class for a long time. Can Malay fanciers—alas, their name is not legion, expect this to go on when they refrain from entering the lists?

The Any other distinct variety class gave the Judges very great trouble, so report says. It is quite necessary that an alteration should be made here. The Houdans, La Flèche, Crève Cœurs, &c., might be grouped together, as I have before suggested, into a class under the heading of "French Fowls." At Salisbury with such a class there would have been a dozen entries. I greatly admired the Crève—no; what am I writing? I do not think I ever can—no! it was the Cuckoo Cochins. They were awarded second, or extra second prize, and very beautiful I thought they looked.

The single cock Spanish were very poor; one or two had been good, and one or two never would be. In the Dorking class was a beautiful unnoticed white bird, very large, but with a single comb. He had the deformed spur, now so often seen, the spur growing outside the leg; still, I thought him the best bird in the class. The noticed Cochins were very good. Mr.. Boyle was first in Brahmas; again a goodly number of entries. The first-prize cock, a beautiful bird, was very nearly blind. I noticed a cock in pen 57, I think, that was also in the same condition. The Game, as I have said before, was headed by a bird in beautiful condition, belonging to the Rev. A. G. Brooke. Silver Polands were first in the Any other variety, Crève Cœur second.

Ducks were good, I should imagine. The first and second-prize pens in the Any other variety class were charming specimens; but what they were the catalogue failed to inform us.

The *Bantam* classes I only glanced at. Gold or Silver-laced, truly, —Cæsar and Pompey very much alike, especially Cæsar; it really was hard to say which was which. It is very sad to think that this beautiful mongrel, if you will, but still most beautiful breed, should fade away; but it appears by no means improbable.

As I have already remarked, the Brahmas entered in largest numbers. I only deduce from this fact that great shows should offer the same prizes in amount to all the classes that generally fill fairly. The promoters do not know, and cannot possibly fathom the eccentricities of entries. Who could foresee the position of Brahmas this year? And who, remembering that last year Malays beat Buff Cochin and some other classes, who, I repeat, could foresee the solitary entry? I do not intend to argue from this that Malays should have as large prizes as Buff Cochin and the more useful classes; they do not deserve it, I am sorry to say. The change from two hens to one—a point I have constantly advocated in these pages, was tried for the first time. How delighted the poor birds must have been, for the glorious summer so prayed for by us mortals did not certainly add to the comforts of our poor prisoners. Nearly every class showed this more or less: the open beak, the panting chest, the extended wings, told how they suffered. The birds were most carefully attended to—too much food, if anything, being given; but the hard barley—not the finest specimen, by-the-by, that strewed the pens which were untenanted, showed the great error committed in the first meal offered to the birds. It is well known now, and frequently is acted on, that soft food, and that sparingly given, should be the first meal; if this precaution is necessary at Christmas, it is doubly imperative at this season of the year. I did not notice a single pen ticketed "sold." This was strange, I think; but Tuesday was my day of visiting the Show. The catalogue, as I purchased it, was minus the prize list.—Y. B. A. Z.

VITALITY RETAINED IN CHILLED EGGS.

I SAT a hen on eleven Duck eggs on May 13th. The nest was in a tea-chest, and there was a row of such for other hens to lay in, and the position being high and, as I thought, too dry, considering the habits of the Duck, I used generally to sprinkle the eggs when the hen was off. After she had sat a fortnight, however, more effectually to moisten the eggs I put under them some damp short grass half made into hay, and to my surprise twenty-four hours afterwards I found the old favourite Game hen (which had always been so good a sitter and mother), on a chalk egg in the next box—the eggs as cold as stones, and damp too. I put her on them, hoping against hope that they might hatch, and determined that she should have her sit out. Her time was up on the 10th of June, and to my surprise nearly all the eggs were chipped on the 9th, and she hatched the whole of the eleven eggs, which are now fine healthy little ducklings. I am sure she was off her eggs quite twenty-four hours.—PETER HAMMOND.

BAR-FRAME HIVES.

IN the latter part of the last paragraph but one of "Our Letter Box," page 402, I find the bar-frame system of hive referred to as "of German and American invention." Perhaps you will do me the favour to allow me to state that the bar-frame hive (or skeleton hive within a hive or box), which has been found to be the only approach to the natural "habitat" of the honey bee, may be used in all climates, and has superseded the advantages that straw hives had previously held over wooden boxes as non-conductors of heat and absorbents of moisture, was originally the invention of an Englishman, and was first introduced by Major Munn in his bar-frame hive, or skeleton hive within a hive, many years ago. I therefore beg to state that the invention of the bar-frame hive is due to this country (England), and it is not either of German or American origin.—SUDBURY.

[The rudiments of the modern rectangular frame hives may

certainly be discerned in the three-cornered frames of the very ingenious but somewhat unpractical "bar-and-frame hive" invented and patented by Major Munn, and described by him in a pamphlet first published in 1844. The validity of Mr. Langstroth's patent in America has, in point of fact, been unavailingly disputed on this very ground. If, however, we are to go back to rudiments and first principles, we should be inclined to ascribe the original invention to Huber, who, during the last century, used rectangular frame, or, as he denominated them, "leaf" hives, which only require the addition of an outside casing to approximate very nearly to the German frame hives of the present day. Upon the whole, therefore, we are disposed to indorse the decision arrived at by the trans-Atlantic law courts, and consider that we are indebted to the Baron von Berlepsch in Germany, and the Rev. L. L. Langstroth in America, for the invention of the practical and convenient frame hives now in such general use and high repute amongst us. We may add, moreover, that we do not find that the frame hive, or skeleton hive within a hive or box, supersedes the advantages which straw holds over wood as a non-conductor of heat, and that for this reason we much prefer frame hives made in straw to wooden ones, even when these latter possess the advantage (?) of the most carefully-devised means of ventilation.]

BEES AND BEE-KEEPING IN EGYPT.

(*Concluded from page* 420.)

The Arab holds the erroneous opinion that at the time of swarming there are several queens in one and the same hive; and that if the stock does not swarm, or he does not divide it, the old mother is always killed by the young queens.

6. "In the middle of summer (August), when the Nile rises and overflows its banks, the Egyptian bee-master cuts out the honeycombs. Whilst this is being done the entrance is stopped, and the disc at the back of the hive being removed, the bees are driven towards the front by means of smoke. A knife having been used to loosen them at the top, perhaps three-fifths of the honey-laden circular-shaped combs are taken out. Combs containing brood-cells are not meddled with; and if at any time the Arab by mistake takes out a comb containing eggs, larvæ, or sealed brood, he immediately returns it again. The destruction of bees by sulphur is unknown."

In Egypt they also follow the swarming and depriving* system. To destroy brood is there held as a sin. What, indeed, would Soliman call those German bee-keepers who teach that at the time of the blooming of the willow (the end of March or beginning of April), one should cut out of the stocks all empty and brood-combs up to the sealed honey at the top? Verily all that they do in strange lands and distant parts of the earth is not so much amiss.

7. "Soliman is truly a great smoker, yet he never employs tobacco in his operations, but smokes bees only with dried cowdung."

I have before stated that the Egyptian bee stings only when irritated, and I now repeat the same in order to avoid mistakes; but on the other hand, if irritated it is extremely vicious.

I at first operated on the imported colony without smoke; and as I was neither stung nor otherwise molested by the bees, I could then with truth assert that the Egyptian bee did not sting. About four weeks afterwards I made use of cigar-smoke when withdrawing an Egyptian brood-comb in order to remove it. I forthwith received eleven stings in the face and five in the hands. The other day I purposely operated with tobacco-smoke, and, having on no bee-cap, was compelled to run away. All recent observations go to prove that tobacco-smoke excites the greatest wrath in the Egyptian bee. With German and Italian bees the human breath produces the same effect. If the ire of an Egyptian stock is once excited, it remains for a long time extremely vicious, and when it has at last calmed down, we need use but a few whiffs of tobacco-smoke to see the rage of the little insect break out again in its full fury. We can understand with what spirit the Egyptian bee sets upon people, when we consider the extraordinary agility and vivacity of the insect. In order to subdue its irritation I use the smoke of decayed willow wood (touchwood), and this converts its courage into embarrassment, despondency, and dread. They will even then fly at the operator, circle round him like mad, and pitch on his face, hands, &c., curving themselves at the same time as if they would sting, but mostly fly off again without having done so. I have not yet tried upon the Egyptians the effect of smoke from dried cowdung.

8. "The Egyptian-cylinder hives are four feet long,† and are made of a compost of Nile mud and cowdung. The Arab makes a mould of reeds, round which he plasters the well-kneaded material to the thickness of about 3 inches. When the cylinder which is thus formed becomes dry, the reedwork is withdrawn. Straw hives are unknown in any part of Egypt. In Upper Egypt, in addition to these cylinders, they also use as bee-hives moveable pots and pans formed of the same material. Stray swarms are frequently discovered on the ground, when, if the finder has not the courage to hive them, and the swarm be on his own land, he takes Nile mud mixed with cowdung, and builds a little hut in the form of an oven, closing up the hole which he has left by means of a door formed of the same material."

Travellers tell us not unfrequently of bee-hives which they have seen in Egypt. So, for example, De Maillet in his *Description de l'Egypte* speaks of "hives," "bee-hives," and "honey-hives." Among the Egyptian "bee-hives" they have not, up to the present time, contrived straw hives, but only cylinders, pots, &c., formed of Nile mud. There is positively no reason whatever for supposing that the ancient Egyptians used straw hives, since straw is, on account of its retention of heat, a most unfit material for bee-hives in this country.

9. "The Egyptians place their bee-hives as near as possible to the clover fields. In the immediate neighbourhood of the cylinder-hives, which are piled up like drain-pipes, is erected a dwelling for the bee-watchman."

Bees collect the most honey from clover. The clover which is so abundantly cultivated in Egypt, Trifolium alexandrinum, should also be cultivated by the Berlin Acclimatisation Society in the experimental fields in Berlin, where, through sowing the original seed, they had such a brilliant result in the year 1862. The plant is an annual, and the seed raised, even on good soil, in this locality, is wanting in the vigour necessary to produce the superior clover which we find in its native country. To import seed annually would, with the high cost of transport and the doubtfulness of the supply, be doubly disadvantageous.

10. "Travelling with bee-stocks is no longer seen in Egypt."

According to various accounts, the ancient Egyptians practised a profitable system of migratory bee-keeping. De Maillet related (1740), that they then still made use of the Nile in order to obtain a rich honey harvest. "In Egypt they have preserved a custom, introduced by the ancients, of maintaining bees in a very peculiar manner. Sainfoin is first sown towards the end of October, when the Nile subsides. As Upper Egypt is hotter than Lower Egypt, and the inundation sooner disappears, the sainfoin there grows and flowers earlier. They, therefore, send their bee-hives from Lower Egypt to the south, in order that the bees may gather from the flowers. The bee-hives are all numbered and piled in a pyramidal form on Nile boats. The bees pasture for some days in the fields, and when it is believed that the chief harvest is over, the boat moves two or three miles northwards, and halts again so long as the bees can profitably remain. At last, in the beginning of February, the boatman returns to the sea and restores the stocks to their owners." Niebuhr also describes migratory bee-keeping in Nile boats. From verbal information imparted to Dr. Gerstäcker, we learn that neither Ehrenberg nor Dr. Hartmann observed during their travels the transportation of bee-hives on the Nile. Hammerschmidt's careful inquiries in the year 1865 have established the fact, that at present migratory bee-keeping is not pursued in Egypt. All modern accounts, therefore, which represent migratory bee-keeping as being still customary in that country, are, of course, unfounded.

11. "The worst enemy which the bees have in Egypt is a long slender wasp, or humble-bee, with a red body. In the latter part of the summer this insect sets itself before the entrance of the hive and kills every bee that comes out. At this season, therefore, a child is stationed in front of the hives with a large fan to drive away the wasps. In the year 1865 the Arab Soliman had in a short time no less than eighteen out of a hundred stocks so completely plundered that they died, and all through the carelessness of the child to whom the watch was intrusted."

What Egyptian insect may be meant by the red-bodied wasp, or humble-bee, I am unable to learn. I hope, however, that those naturalists who are among the readers of our bee

* This deprivation is effected by cutting combs out of the hives.—A Devonshire Bee-keeper.

† About 3 feet 10 inches English measure.

Journal will be able to determine its name from this insufficient description.

12. "W. Hammerschmidt, the photographer, had promised me a photograph of the Arab Soliman, undoubtedly the greatest Egyptian apiarian. At my request, also, Soliman declared that he would gladly permit himself to be photographed; but he soon changed his mind. Even the most civilised Arab cannot understand the nature of the photograph, and therefore views the art as the work of the devil, terrifying accordingly to the ordinary Bedouins and Fellaheen. Friend Soliman very soon began to allege all manner of excuses, such as that he suffered from rheumatism, and was unable to go when Herr Hammerschmidt invited him to accompany him and have his likeness taken; so that all I obtained from the old Soliman was an exchange of compliments."

The reader may, perhaps, be enabled from the information which I have set before him to picture to himself Egyptian bee-keeping. I am indebted for this information almost entirely to Herr Hammerschmidt, who has passed nearly a generation in Egypt, and is a perfect master of the Arabian language, so that an understanding with the Arab became easy. Herr Hammerschmidt obtained answers to a number of questions which I had written, and noted them down immediately. In order not to pervert the sense of Herr Hammerschmidt's memoranda, I have transcribed them almost literally.

We have been far away from home, and right glad are we to be safe back again with wife and child. We intend next to make an excursion to Greece, in order to report upon the bee-keeping in the convent of Cæsarea, one league from Athens, on the front spur of the Hymettus.—W. Vogel.

MEAD OR METHEGLIN. *versus* HONEY BEER.

The American receipt at page 336 for mead or metheglin is very good, and "W. H. S." may, amidst distracting counsels, unhesitatingly trust to it; but a large handful of elder flowers would be much too great a proportion for the palates of nine persons out of ten. One ounce of the dried flowers to a ten-gallon cask would be safer. Elder flowers are very searching, and when wine or anything else is over-flavoured with them, the liquor is generally pronounced to be very disagreeable. Let me also advise, that the "lees remaining in the cask" be thrown away; they are useless after fermentation. I can advise with some authority, as I have been a maker of mead for years. I sent a bottle of it up to one of the Royal Horticultural Society's meetings last April twelvemonth, along with about thirty samples of home-made grape and other wines for judgment. The award my mead gained was this:—"Very disagreeable!" I had previously arrived at the conclusion that mead is not liked as a beverage by the majority of people in these times. Our forefathers were pagans, and considered their mead only sufficiently worthy for the halls of Valhalla, their heaven, to be drunk there in reward for bravery, out of the skulls of the enemies whom they had slaughtered during life! For my part, then, I feel sorry for our forefathers, and I only intend making mead in future for the purpose of turning it into vinegar, because I now manufacture a drink out of honey infinitely superior, I think, for the purpose of quenching thirst. So did the judges, as the award they gave to a bottle of honey beer was, "Very good indeed—a very successful experiment." A bottle of mead-vinegar also gained the following character:—"A very first-class vinegar with a sauce flavour."

I will consider no brewing-plant or fixtures of any description as being necessary, excepting the copper, which would be found to be in most cases already set; but that which I use for my small brewings of honey beer is made of galvanised iron, and holds nine gallons. I temporarily fix it over the kitchen grate. I prefer working the liquor in a large, glazed, earthenware pan, as when a wooden-tub has not been previously used for working malt liquor, it is apt to absorb much of the saccharine matter. We must, of course, have either a large stone bottle or cask to contain the beer, and it should be sweet and in good order. A brewing thermometer costing 3*s.* 6*d.*, and one of Roberts's saccharometers, which costs 6*s.*, are very desirable, as by them the temperature and specific gravity, or sweetness, are correctly shown, entirely doing away with guesswork. The most certain way to procure good hops is to order them from the most respectable dealers. A chief consideration, also, is the barm, or yeast. To procure it fresh and good, find out if some neighbour has lately been brewing, for it is much more likely to be obtained genuine from a private source than from a public-house, in these days of nux vomica, strychnine, and other additions. Half a pint of ale barm, or still better half as much again of small beer yeast, would be sufficient for our present six-gallon brewing; but whatever quantity may be required to eventually fill the jar or cask, allow one-third more water to compensate for waste by evaporation during the boiling, and to make sure of enough for the repeated filling-up of the cask during the working process. Some people prefer hard water, but others say soft water is best to brew malt liquor with. I never in my practice could perceive any difference. I use soft water in brewing honey beer, and the preference seems reasonable; at any rate, when using the saccharometer the temperature of the liquid operated upon must be tested by the thermometer, and brought up or lowered to 60°.

Now, I shall suppose we have arrived at a time—say September, when the bees have quite done honey gathering, that their superfluous stores are taken, and the honey—at least as much of it as will do so without much breaking the combs—run off; then what remains in the combs reclaim by emptying the contents of the canvas bags into a pan, with two quarts of water to two quarts of the honeycomb, first making the water dissolve what honey adheres to the bags by rinsing and wringing them in it. Occasionally stir the mash well with a wooden spoon, and at the expiration of three or four days strain the liquid through a bag or bags, sufficiently fine in their texture to retain every particle of the wax, into a large pan. Measure it, and add the desired quantity of water to compose the brewing. Prove the temperature by the thermometer, and if it is not 60° make it so by adding some hot water. Now, for strict economy's sake, collect any odds and ends of last year's honey remaining uselessly on hand, or any of that of the present year which appears discoloured, or not of sufficient quality to command a first-rate market price, and keep mixing it till it is quite dissolved and blended with the water in the pan. Continue to test the sweetened water with the saccharometer till the latter floats at the degree or specific gravity of 40°, marked on its index-plate (equal to 200° by Thompson's saccharometer, a more scientific and expensive instrument, costing at least ten times as much as Roberts's)—that is, equal to within a fraction of 3½ lbs. of honey to the gallon of water.

Supposing the pan to contain for our six-gallon brewing nine gallons of what I shall call sweet wort, we will immediately enter it into the boiler, and there add to it not quite half a pound of hops, rubbing and separating them well between the hands, as we do so incorporating them well with the liquor, using a large wooden spoon, and not interfering again till it begins to boil. Watch it narrowly, for if, through negligence, it should boil over at this stage, almost before you can think it will be all out of the copper. As soon as the hops heave and break, and foam appears through the fissures, look at the clock. The process must now have your undivided attention for about an hour; allow the liquor to boil freely for that time, coaxing it within bounds with the mash stick or wooden spoon; but if it persists in boiling too violently damp the fire with some moistened slack coal, which it is advisable to have at hand. After the first hour the liquid will naturally boil more gently; then cast into it about 2 ozs. of salt. Allow it to simmer gently an hour and a half longer: "A slow brewer and a quick baker" is a proverb. Clear, well-flavoured beer, let it be made either with malt or honey, to stand the proof of keeping cannot be had unless it be well boiled, nor can the virtue be extracted from malt unless it be well mashed. Now place a tub near the copper, suspend a sieve, or strainer of that sort, over the tub, and lade the beer from the boiler into the strainer, where the hops will be retained, and this done, immediately pour some water into the boiler, if it be a fixture, to prevent the fire burning a hole in the bottom. Move off the strained beer to a cool place (my plan is to carry it at once into the cellar and enter it into a cooler); in doing so be careful not to spill any, as we are brewing to close measure.

I have now said all that I think necessary to initiate cottagers who may be the possessors of but a few bee hives, into what large brewers in my native county of Suffolk sneer at as "tea-kettle brewings." But never mind, we cannot be all large brewers; and "tea-kettle brewers" do know what they drink, and so far as my observations of them have gone they are inclined to keep sober. I want to knock at the door of the cottage *ornée* as well as that of the cottage proper, so I will finish this paper on the supposition that we are brewing fifty gallons of honey beer, and point out the manner in which the fermentation of the larger quantity should be conducted, the process being the same in both cases, only that the larger quantity requires more time, and there is more complication attending its management which it will be as well to explain.

The working tub must not be placed in the way of cold draughts, but close to the cask intended to be filled. Tilt the tub, by placing something for the edge of its bottom to rest upon, and then pour into it about six gallons of beer set previously apart to cool. Plunge the thermometer into it, and make sure that its temperature is lowered to 70° at least. This temperature (milkwarm), is the proper degree of heat to apply the yeast, which must be thoroughly mixed with the beer; then place the lading-bucket, which should be made of wood, with its handle inverted, in the midst of it, and this will be found to considerably expedite the fermentation, which invariably begins at the point of contact with the bucket. Separate from the cooler double the quantity of beer just set to work in a different tub, to be added to that in the working tub when the ferment is causing a white froth to be formed upon the surface. Be very particular as to this; until a white "head" is well formed over do not add more beer, or fermentation may be checked in the beginning, and the working rendered precarious afterwards. Let the formation of the "head" act as a guide for future additions, and whenever one is made, separate more beer to become cooled, each time doubling the quantity. Of course, you have to untilt the working-tub when you add the second quantity. Malt liquor is set to work exactly in the same manner as I have just described, and should you previously have been a brewer of it, do not become frightened at the more sluggish fermentation of honey beer. The process of fermentation is longer, and never so active as in beer

made from malt. Should the honey beer cool down too much in the cooler before it can all be got together, bring up its temperature by reheating a portion of it in a saucepan, or prevent the escape of heat by covering the cooler over with some sacks or old carpeting. Patience is a virtue in carrying out the fermentation of honey beer, as I believe it to be in most other operations.

Now, we will place our cask firmly and level on a skeleton tram, elevated a foot or so from the floor, so that by a free circulation of air beneath it may be preserved from damp and injury. Make two cork-holes, or one as the case may be; two holes are better, one below the other in the centre of the barrel. Take out the vent-peg, allow the bunghole to lean slightly to one side for the purpose of casting off the scum, because, as I just mentioned, the fermentation is sluggish, and will scarcely if ever render a working-tube necessary; slip a pan under the barrel to catch the scum, adjust the tun-pail in the bung-hole, and the vessel is ready to be filled. Directly the beer is all in the working-tub, let this part of the proceeding be completed, and when the cask is nearly full froth will issue violently, then take away the tun-pail, complete the filling-up with a spouted jug quietly, and remove the pan or other vessel from beneath; empty it and replace it. Should the filling of the barrel be done in the evening, it would be as well to rise in the middle of the night and attend to it in case the fermentation should have begun and more liquor is wanted to keep the cask full. Now the necessity will be seen for having some to spare for that purpose.

In the event of the beer showing no sign of working in the barrel after the expiration of forty-eight hours, it will be necessary to encourage it to do so. Take a double handful of flour, place it on a plate before the fire, and stir to prevent its burning till it becomes quite hot, grating into it in the meantime about 1 oz. of ginger. Enter this by degrees with the left hand in at the bunghole, and keep stirring it about the liquor in the cask with a stout lath quickly with the right hand, so as thoroughly to mix the whole, and, doubtless, the fermentation will soon commence. The temperature of the place where the cask is set to work should, if possible, not be much below 60°. No given time can be stated when fermentation will cease, but it must not be allowed to go on too long, and as soon as it becomes gentle, and the liquor has become apparently fine, rack it off. At this stage the saccharometer would be found of the greatest consequence, as this is just the time when nine people out of ten allow their wines, &c., to enter into the acetous fermentation unwittingly, from not knowing the specific gravity. As soon as the liquor has attenuated itself by fermentation to 9°, by Roberts's saccharometer, which can be ascertained by occasionally floating the instrument at the bunghole, the contents of the cask should be immediately racked off, and the settlings or lees rinsed and drained from the barrel, mixed with twice their bulk of water, and applied to the roots of the rose trees showing the most blossom-buds.

After having cleaned the cask, turn it bunghole downwards, and fix it in that position. Then at the end of an old iron spoon place about 1 oz. of flowers of sulphur, set light to it by the flame of a candle, place it at the mouth of the bunghole, and allow the fumes to enter the barrel. As soon as the sulphur is burnt out, replace the cask, and enter the honey beer into it again immediately. Further fermentation will by this proceeding be nearly if not entirely arrested, and there will be no danger of the liquor becoming sour. It has also the effect of fining down and brightening it.

The cask may safely be bunged down tightly in three weeks after the racking. I ought, perhaps, to explain how to do that also. Force in the cork at the bottom of the barrel and allow the beer to escape into a cooler; tilt the vessel when it begins to run slowly until the thick grounds are perceived to escape; then untilt immediately, fasten in a new cork, and proceed as above stated. An underground cellar is always to be preferred, on account of its being warm in winter and cool in summer. We cottagers cannot often command such, but, wherever it may be, an even temperature of 50° is desirable. Frost and strong light should be avoided, and gleams of sun must be as carefully excluded as from a dairy.

DIGEST.

To make a Strong Honey beer.

Quantity to be brewed ..	50 galls.
Water required.....	67 galls.
Proper temperature of water to prove by saccharometer	60°
Proper sweetness of wort by Roberts's saccharometer	40°
Or, quantity of honey at 8¾ lbs. per gallon.....	234½ lbs.
Do. of hops if required to keep 12 months	4 lbs.
Do. of hops if for 6 months	3 lbs.
Do. of barm for working	3 pints
Time for boiling the beer	2½ hrs.
A good handful of salt thrown in after first hour's boiling.	
Quantity to begin to set to work with	6 galls.
Proper heat to set to work	70°
Time for brewing—September or October.	

—UPWARDS AND ONWARDS.

DIGEST.

A Table Honey beer Brewing.

Quantity to be brewed ..	50 galls.
Do. of water required....	67 galls.
Do. of honey, 2 lbs. per gallon	134 lbs.
Do. of hops	2 lbs.
Do. of barm for working..	2 qrts.
The table beer requires a larger proportion of barm to carry out the fermentation than the strong beer.	
Time for boiling	2½ hrs.
A good handful of salt thrown in after first hour's boiling.	
Quantity to begin the working	5 galls.
Proper temperature to set to work	80°
Times for brewing—In the spring and summer as wanted, and to be drunk directly it is racked and becomes fine in the cask.	

BEES AT THE MANCHESTER NATIONAL HORTICULTURAL EXHIBITION.—We learn from the *Manchester Courier* that at the National Horticultural Exhibition recently held at the Botanical Gardens, Old Trafford, Mr. Carr exhibited two stocks of Ligurian bees; one being in an "improved observatory revolving bar-frame hive," and the other in an "improved unicomb observatory revolving bar-frame hive." He also exhibited what is stated to be "the finest bell-glass filled with upwards of 32 lbs. of the most splendid honeycomb ever collected in Lancashire," and frames filled with honeycombs weighing from 6 to 7 lbs. each. Our contemporary pronounces the exhibition to have been altogether most successful.

OUR LETTER BOX.

CHICKENS DYING (*An old Cocker*).—The present warm weather will be the most effectual remedy for the diarrhœa in your chickens. A little bread soaked in ale once a-day, and a good supply of lettuce leaves to peck will be good treatment, in addition to oats, grits, and soft food.

FOOD FOR BANTAM CHICKENS (*M. B.*).—Custard and oatmeal would make very good food for Bantam or any other chickens. We should not think it too fattening, but we should give plainer food with it, both for a change and to prevent cloying. We do not know the Canary wine.

HENS SOLD FOR PULLETS (*Justitia*).—Birds of 1866 would not be considered pullets in June, 1867. A pullet is always considered a bird of the year. There is no age that constitutes a pullet or otherwise, after the end of the year in which it was hatched. Thus, if it could be proved, a bird hatched on the last day of December, 1866, could not be shown in the pullet classes at Birmingham next December; but one hatched on the 1st of January would be strictly within the rules, although the difference in age would be only a few hours. At shows held after Christmas, if there are pullet classes, it is thought advisable to add to the word "pullet," hatched in 1865, 6, 7, as the case may be. We have pullets of this year that show signs of being broody. (*G. H. W.*).—You should not be put to any expense in the matter. We do not think you have been treated aright in the transaction. You are unfortunate enough to obtain only three chickens from two sittings of eggs. The cockerel appears to be good, the pullets not good enough to exhibit with hope of success. You apply for two pullets, and choose the highest priced, in order to make an exhibition pen. This must consist of all chickens or all adults, unless it be for open competition in an all-aged class. A cock hatched in 1867, and two hens hatched in 1866, would not form a pen. Late birds are not desirable, and those now eleven months old must have been hatched last August. Those sent to you are hens, and cannot possibly be described as pullets.

INCUBATOR REGULATOR.—In answer to "K.," I recollect seeing such a thing many years ago in Kemp's shop for chemical apparatus, in Edinburgh. The regulator was not for sale, but was at work in the shop, something requiring a fixed temperature under boiling point for its preparation was placed in a water-bath, and a thermometer in the water-bath regulated the flow of gas. I cannot now remember the form of connection between the thermometer and the gas-pipe; but if Kemp's business is still carried on in Infirmary Street, close to the University, some of your Edinburgh subscribers or correspondents might procure a drawing of the apparatus for you.—MONTICOLA.

COCK'S FEET CRAMPED (*A. W.*).—Give him bread soaked in ale once daily, and plenty of lettuce leaves; keep him in a warm dry place. When settled dry and warm weather arrives, let him go where he pleases.

CAMPHOR ADMINISTERED TO CURE GAPES (*T. V.*).—The dose for a chicken five or six weeks old is a pill of camphor the size of a small garden pea. Where the camphor julep given to them to drink is strong, they seldom require a pill. It is the odour of the camphor that kills, there is no real contact with it. It is impossible, because the parasites are in the windpipe.

FOWLS EATING EACH OTHER'S FEATHERS (*Constant Reader*).—We can only repeat the advice we gave last week. This propensity only comes to those that are in confinement. Birds that are at liberty never fall into it. It arises from a bad state of body; this is caused by confinement and deprivation of something they get when they are at liberty. We speak practically. Ours are cured by lettuce, sods of grass, and fresh earth.

CANARY'S WING-FEATHERS DISEASED AT THEIR ROOT (*C. A. J.*).—The bird with quill-end of feathers full of blood is affected with the scurf, which irritates the skin and causes the bird to peck the roots of the feathers, and makes them stick out irregularly, bleed, and fall off. Get a little cold cream at a chemist's and apply it to any parts naked with a feather. Place a small pan of lukewarm water in the cage for the bird to bathe, and if it will not bathe, take a squirt or a little in the mouth and spirt over it from behind, so that the water may go under the feathers, and let it dry before a fire if there is no sun. Repeat this on several days. Soak a piece of stale bread in hot water to extract the alum, squeeze the water out, and then add a little milk and mawseed to it and squeeze rather dry, give it to the bird while warm. Examine the cage and nest and see if there be any insects. Gas, smoke, or cold would cause the waning of the bird, also the feathers to drop off. Give plenty of air.

POULTRY MARKET.—JUNE 19.

THIS season will rank as one of the extraordinary ones. Had there been anything like the average demand, such prices would have been given as were never before heard of. There is still but a very moderate supply.

From observations taken near London during the last forty years, the average day temperature of the week is 73.3°; and its night temperature 49.5°. The greatest heat was 91°, on the 30th, 1862; and the lowest cold 34°, on the 26th, 1864; and 30th, 1863. The greatest fall of rain was 1.18 inch.

BLOOMING PRIMULA SINENSIS A SECOND YEAR.

HOW beautiful these Primulas are! What lovely Primulas!" exclaimed my lady on her return after a year's absence from home. "We never had such fine plants or any so well bloomed before!" and my lady and her daughter were in ecstacies, for they were "fond, extremely fond of Primulas." But who is there that is not delighted to see one of those lovely flowers with its rich masses of beautifully-formed rose or carmine blossoms, and its serrated foliage? or its equally lovely masses of white, vieing in purity with the snow outside as it is falling upon the earth?

Yes, the Chinese Primula is indeed a valuable and indispensable addition to our winter-blooming plants. Who, possessing a greenhouse, however small, does not try to grow a few Primulas to grace with their presence his room during the Christmas parties? there, in the depth of winter, whispering of sunshine, and verdure, and flowers to come after all the frosts and snows. True messengers of spring they are.

"But what a pity," observed my lady, "that they will so soon have to be thrown away" "No," your ladyship, "I do not throw them away." "Then, will you plant them out in summer in the flower garden, as I have sometimes seen them at places? but the wind breaks them, and they look untidy. I never like to see them." "Well, but that is not my object. Those Primulas have a history which I will relate."

So I proceeded in my narrative.

I always sow the Primula seed about the middle of February, and as soon as the seedlings are fit to handle I pot them singly in 60-sized pots, using a compost of one-half turfy loam, one-half leaf mould, manure, and sand. Then they are placed in a warm pit for a week or two, when they will be making good growth. Then a shift is given them into pots a size larger, and they are placed on a shelf in the greenhouse, there to stay until I see them open a flower to prove them. Such as are not well fimbriated, or of well-defined colours, I at once discard. I pot the remainder in their blooming-pots, and place them back on the shelf, or in a cool pit or frame, there to stay until taken in for the winter.

The second year, however, is what I look upon as the best (the plants my lady saw were two years old); therefore, when the bloom is over I take the plants, clear them of any dead leaves or flower-stalks, and see that they are clean and healthy. I then place them in a cold pit or frame until about the middle of July, when they are re-potted, shaking off most of the old soil, but still leaving some undisturbed. I am very careful that they are clean, and not too deeply potted, as they are very impatient of moisture at the base of the leafstalks, and if potted too deeply, in dull damp weather the foliage damps off, and they look unsightly objects compared with those having good foliage.

I am also careful never to allow them to waste their strength during summer by blooming, which, if not prevented, they will do. I pinch off all flowers as soon as I see them, until I want the plants to bloom. "Then," inquired my lady, "is the plan a new one, and your own suggestion?"

"By no means. Certainly I never saw the method carried out, or even heard of it, and I have spoken to a few neighbours, who say they have not seen it tried. Still, I have every reason to believe that this course of culture is older than myself." Thus the tale ended.

Perhaps some of your readers may, like myself, have been so used to fresh seedlings every year, that they, too, have lost sight of this mode of culture. To such I would say, Try it.

Of course I always sow a pot of fresh seed every year.—J. Y., *Eccleshill Hall.*

HEATING SMALL PLANT-HOUSES.

"Subscriber" is having a small greenhouse (8 feet by 8 feet), put up, and being an amateur in but a small way, she objects to stoves that require coke, charcoal, or patent fuel, as, where she resides, such would be troublesome to procure, and expensive. She is told that a stove burning coal or slack would not do for the flowers; and, again, hot-water apparatus would be difficult to put up, the space being so small to work upon. Will you say if heating by a brick flue would do for flowers, and in that case how should it be managed so as to keep up a moist heat, which is so conducive to the well-doing of plants?

[There is so much needless mystery, and something like the making a "job" as to the heating of small greenhouses, that thousands are deterred from having these sources of pleasure close to their dwelling, and thousands more act on the advice which Mr. Tyerman, of the Liverpool Botanic Gardens, told us he frequently gives where there would be much trouble and expense in heating in winter—namely, to supply with flowering plants in summer, and to fill with ornamental-foliaged hardy evergreens in winter. This plan, however, deprives the enthusiastic amateur of the chief relish of such a house—the pleasure of growing and attending to his own plants, and keeping them on from year to year. The finest plants bought in when in bloom will never exert the peculiar pleasing influence that plants even not so fine will do when they have been reared, potted, and watered with our own hands, and otherwise tended under our own supervision. Then our pet plants become, as it were, part of ourselves, being so interwoven and blended with all our sympathies.

Again, though it is pleasant to have a greenhouse in summer, it has less attractions then, when everything out of doors is growing and flowering, and we become, if any-

thing, bewildered by the number of blooming beauties that are soliciting our attention. It is in winter, when all outside is bleak and bare, when the ground is hard, covered with snow, or the storm rages, and the pitiless rains descend, that a few plants in bloom in our windows or in a little greenhouse present their chief charms; and hence we would advise every one who has such a greenhouse to try some simple means for keeping the frost from his favourite plants. Some time ago we chronicled how large plants of Scarlet Pelargoniums stood in rather a large lofty house last winter, and had no assistance whatever in the coldest nights, except opening for a couple of hours or so the door that connected the place with the living-room. These plants lost most of their leaves, and looked rather badly in March, but now they are huge masses of scarlet, and no one would think they had come through such an ordeal. A small stove in such a place would have kept them green enough.

Now, to our correspondent, who is anxious to keep the cold out of her house, we will at once state that a stove, a flue, or hot water will do admirably for her; and as she cannot have a stove that will require prepared fuel, then, as the cheapest and quite effectual for all the purposes she wants, we would recommend an iron stove which can be set outside in summer, and that will burn coke or cinders, and have a pipe, 3 inches in diameter, to go out of the house; one of the simplest modes being removing a square of glass, and putting in a square of zinc, or galvanised or sheet iron in its place, with a hole in the centre to admit the pipe passing through. Except where a pipe can be taken from a kitchen boiler, it is very expensive in proportion to the size to heat a small house by hot water. It is much cheaper to do it by a flue. We thus heated a small house by a flue beneath the floor for little more than as many shillings as a hot-water apparatus manufacturer said he would want pounds. For so small a house we would be satisfied with a small stove.

To prevent the evil effects of dry stove heating, and to insure the moisture which our correspondent desires, two essentials must be secured. First, the stove, however small, should be large enough to permit of the firebox being fixed inside, free of the sides of the stove; and, secondly, the top of the stove should be flat, so as to permit of an iron vessel of the same size, as to width, standing on it, supplied with water. For this purpose it is best that the smoke-pipe should issue from the side near the top of the stove, instead of from the top itself, and that, after going a foot or 15 inches horizontally, it should have a joint, and go straight up through the roof. It matters not whether the stove is round or square if these conditions are attended to. For such a place as "Subscriber's," the stove might be 18 or 20 inches in height, and 1 foot in diameter or square, and the firebox inside be 7½ or 8 inches in diameter or square. The evaporating-pan might be the same width, and 8 inches deep, so as always, when much fire was used, to have a little water in it. In very severe weather a little water could also be poured on the floor near the stove. Plenty of stoves can be procured with all these conditions. The reasons why the firebox should not reach the sides were lately given. Were we to have a little stove of the kind made, then we would have a double moveable top to it, the inner part of rough plate iron, to go in a groove and to be covered with sand, and the upper to be of a somewhat ornamental character. This will both prevent the top becoming too hot, and allow of the inside centre being easily examined at any time. The draught should be regulated by openings in the ashpit door.]

POTATOES.

Early-planted Potatoes have been, I hear, much injured by the severe May frosts. Here Rivers's Royal Ashleaf, which was 9 inches high at the time of the frosts, is the only one that seems to have materially suffered. I hear that the small tubers of sorts cut down have put out young Potatoes. I bought a sack of Salmon Kidney to eat, and the price was 16s. I hope we shall have lower prices next year. I planted the following four sorts 5 inches deep on the 13th of February, under grass clods freshly broken up—namely, Grammars, Red Robins, Scotch Rocks, and Salmon Kidneys, and they are uninjured, and a capital plantation. I have had them hacked and slightly earthed up. They were previously dressed with 2 ozs. of blue vitriol to the stable-bucketful of water.

"Upwards and Onwards" was so kind as to send me several varieties, which were severely dressed with blue vitriol. Among them was Premier, the handsomest Potato I ever saw—a Kidney; I did not like it. The others, which have come up well and are very strong, having been uninjured by the frosts, were Fenn's Onwards, Pebble White, Gryffe Castle Seedling, Scotch Rocks and Yorkshire Hero (both here before), Shutford Seedling, and Prolific Seedling. Fenn's Onwards takes my fancy much, both tuber and plant. It is marked in my book, "Round, second early, first-rate." Premier is a Kidney, marked, "Splendid, first-rate." Pebble White is marked, "Kidney, late, excellent, first-rate." Gryffe Castle Seedling reads thus in my book, "Roundish oblong, rough skin, which in round Potatoes indicates fine flavour." I find that Kidney Potatoes strongly vitriolised do not come up well, neither will they stand being "chimped." I will report on some of the sorts sent. On the whole I am satisfied with prospects here. I enclose, by permission, the letter I received from "Upwards and Onwards."
—W. F. Radclyffe, *Okeford Fitzpaine.*

P.S.—"Nameless" and Yorkshire Hero were severely vitriolised, planted, and dug up again before sent to "Upwards and Onwards:" hence failure. Some Potatoes are more tender than others about their eyes.

[The following is an extract from the letter of "Upwards and Onwards."]

"I have seven sorts in competition in sheltered corners; these escaped from the frosts scathless. Those in the open ground, on my usual ridge plan, fared worse, though much better than those of my neighbours who planted on the flat. It is worthy of observation that one row of the old Ashleaf Kidney, which I planted on the flat between two rows of Asparagus, for the purpose of early household use, without earthing even, were killed down to the ground, even to the destruction of some of the tubers. In short, the Potatoes have suffered more in these parts from the severe pinching they had than has been known in the memory of the 'oldest inhabitant.'

"I am sorry to tell you also, that the tubers to a great extent are showing no signs of recovery. Mine are now looking as 'sprack' as if nothing had happened, excepting the Ashleaf row, though I must own that Premier, Sussex Kidney, Sutton's Racehorse, and Empress Eugénie do not seem to have liked it. The Emperor Napoleon, however, stood out the frosts triumphantly; but whether it was by mere chance, or whether it is constitutionally 'frost-resisting,' it is difficult to say, for in the majority of the sorts—I have fifty kinds competing this year—a solitary top or two escaped being frostbitten. Nevertheless, as the Emperor altogether escaped, I will give it the benefit of the doubt, and call it a most 'frost-resisting' variety. Yorkshire Hero did not maintain that character with me. I have two rows of Onwards. It has a distinct, robust character, which at once distinguishes it from its compeers in this garden. We had some store tubers of the sort for dinner the day before yesterday; they were quite firm before being cooked, and quite up to the mark as regards appearance and flavour at table.

"I have upwards of one hundred young plants from the berries produced by flowers which I fertilised last year, and which will certainly yield tubers; they are the results from 164 seeds sown.

"Mr. Fish's observations about diseased Potatoes, at page 412, is another step in the direction of the electrical theory. He says, 'All at once, after a thunderstorm, followed by some days of bright sunshine, the tops showed signs of distress, &c. Another puzzling circumstance is that one end of the bed *is* still perfectly healthy.' Exactly! those which became affected were at the midstage of their growth, the age at which I have always found them most susceptible. Those at the other end of the bed were younger, and they escaped. They would have been affected like the rest if they had been of more mature growth. The cool non-electric state of the air just now is very favourable to the well-doing of Potatoes, and on this account I trust no thunder and lightning will visit us for some time."

At page 412 there is a description of a failure in Potato stems, and the question is asked if similar manifestations have been noticed. Although, probably, my garden is more than three hundred miles from the place where these symptoms have appeared, yet a precisely similar condition of things exists here (Cornwall) in my own and some neighbouring gardens.

I have carefully examined the stems which have rotted down, I find they are solely those of the Scotch Regents; Early Frames, Kidneys, Flukes, and others have no instances amongst them, and this holds good in the other gardens alluded to. From watching them and from examination of the stems, I feel

convinced that the rottenness arises from the very wet and windy season we have had. The stems with me having grown rather luxuriantly, they were violently swayed by the wind, and by degrees revolved, as it were, in the ground, and so cut their own throats; for in each instance the rottenness is found where the action such as I describe it would be felt by the stem. The other kinds to which I have referred escape, owing, I believe, to their more sturdy growth, and to having a more sheltered position. The tenderness of the Regent stem marking it out as the first victim for blight is well known; this more delicate habit, with the peculiarly unseasonable weather, with us I consider to be the cause of this failure.—Subscriber.

WHAT IS A VARIEGATED PELARGONIUM?

Many raisers of Variegated Pelargoniums are very anxious to have this matter definitely settled, so that no mistake may occur at any exhibition where they may exhibit their varieties.

At the forthcoming Bury St. Edmunds Show one of the special prizes, a silver cup valued at £10 10*s.*, is offered for the best twelve seedling Variegated Pelargoniums of 1866 and 1867. Two other prizes are also offered in Classes 18 and 19 for six Variegated Pelargoniums. In Class 18 the subjects invited are described as six Variegated Pelargoniums including Nosegays, distinct varieties. There are very few Nosegays that I have seen that have more than two colours in the leaf. If Pelargoniums of the Bronze and Gold section are to be excluded from collections for which the £10 10*s.* prize is offered, what is to be done in the class for six Variegated, in which Nosegays are admissible?

I think the schedule in its present form is likely to mislead many intending exhibitors at the forthcoming Exhibition, and to occasion the jurors at that Exhibition much trouble and unpleasantness.

I maintain that any departure from the normal state must be variegation. If, as I understand by a communication lately received, a collection competing for the £10 10*s.* prize would be disqualified if containing plants belonging to the Bronze and Gold section, then I say the old Manglesii, Flower of the Day, Bijou, &c., are no longer Variegated Pelargoniums; and if not, what are they? I shall, therefore, feel obliged if the Editors will give us the benefit of their opinion. I also hope correspondents will give us their views on the matter.

I enclose leaves of several of my Bronze and Gold varieties, also leaves of a new section. The latter have only two colonrs in the leaf. Several of the Bronze have three; but if the Bronze and Gold cannot be considered variegated, the leaves of the pretty varieties named above cannot be variegated. I trust the Council of the Royal Horticultural Society will inform exhibitors by advertisement as early as possible, that all varieties with leaves containing more than one colour are variegated and eligible, and that such varieties may be exhibited without being disqualified at the forthcoming Bury St. Edmunds Exhibition. If something of this sort be not done, I think few exhibitors from a distance will bring their plants to the Exhibition. Mr. D. T. Fish wishes to see everything of beauty exhibited on that occasion. I therefore hope he will give us his views on the matter, and also try to induce the Council of the Royal Horticultural Society to adopt some measure similar to that which I have suggested above.—J. Wills.

[We have no doubt, if the words of the prize list remain unexplained, that any Pelargonium having another colour in it except the ordinary green and the dark zone, or horseshoe, is admissible to compete for the County silver cup, and in Classes 18 and 19; for that prize list does not even employ the word "Zonal."

To remove all doubts, we hope that the Society's Council will publicly announce the varieties they intend to be included under the general term of "Variegated Pelargoniums."

To avoid ambiguity, Zonal Pelargoniums, we think, should be divided into four sections, each with its special designation and characteristics.

1. Zonal Pelargoniums (the old Horseshoe), having green leaves with a dark zone.

2. Variegated Zonal Pelargoniums, having green leaves with a dark zone, and edged, or otherwise marked, with white or yellow.

3. Golden Zonal Pelargoniums, having yellow leaves and a dark or coloured zone.

4. Versicolor Zonal Pelargoniums, having leaves partly green, but marked with two or more additional colours, and zone partially or entirely red.

Such a division may be considered arbitrary, but it has the great advantage of certainty—enabling competitors to foreknow clearly against what and with what they must contend. It would also proportionately lessen the difficulties of the Judges. —Eds.]

THE EDINBURGH WORKING MEN'S FLOWER SHOW.

This is fixed to take place on the 3rd of August next.

"The Show of 1866 was a complete success. It was held in the Corn Exchange, Grassmarket, on Saturday, 28th July. It is estimated that upwards of 5000 persons visited it in the course of the day, 4000 having paid 1*d.* each admission after two o'clock. In all, there were 245 competitors, 80 of whom entered in Class IV. as 'Juveniles under fifteen years of age;' and, in addition, there were about 30 exhibitors, including several nurserymen, who kindly brought forward valuable and interesting collections of plants. (At the former Show, there were only 160 competitors.) There were 481 entries of plants, &c., for competition.

"The number of successful competitors was 133, to whom were awarded 220 prizes, including a number of 'specials,' amounting in all to £21 6*s.* 9*d.*

"The unanimous opinion of the Judges was, that, compared with the Show of 1865, a most decided improvement in the quality and appearance of the plants exhibited had taken place, showing increased care and skill in culture; and testifying to the fact that the experience gained during the former year had gone far to assist in educating the people in the cultivation of flowers, even at smoky windows, and other situations equally unfavourable to floriculture.

"The Committee are pleased to announce that during the past year a permanent fund, in support of the Working Men's Flower Show, was originated by the handsome donation of £100 sterling from the late Bailie Alexander, as trustee of the late John Mackenzie, Esq., 8, Manor Place, Edinburgh, the interest of which will be applied to payment of a series of prizes to be designated the 'Mackenzie Prizes;' and the Committee hope that additions to this fund will be made from time to time by parties interested in this movement.

"A new feature of last year's Show, which imparted to it considerable interest, was the district competition—prizes having been offered for plants grown in specified districts, in addition to those open to residents in any part of the city.

"In beginning operations for the ensuing summer, the Committee would earnestly solicit a renewal of the liberality of their friends. Bills, containing full particulars relative to the Working Men's Flower Show for 1867, may be had on application to—W. P. Drummond, *Secretary*, 52, *George Street*, *Edinburgh*."

HARDY PLANTS IN FLOWER IN EARLY SPRING.

BITTON, GLOUCESTERSHIRE.

March 1. Epimedium pinnatum elegans
Erythronium dens-canis
Narcissus pumilus
Primula helvetica marginata major
„ 2. Helleborus viridis
Pulmonaria officinalis officinalis alba
„ 7. Mandragora præcox
Scilla nivalis (præcox?)
Soldanella Clusii
„ 9. Luzula sylvatica var.
„ 16. Iris tuberosa
„ 22. Apricot
Sanguinaria canadensis
„ 23. Anemone pavonina
Draba verna aizoides
Tussilago farfara farfara variegata
Scilla bifolia rubra
„ 25. Narcissus calathinus odorus cernuus
March 25. Narcissus cernuus plenus pumilus plenus Curtisii

Cydonia japonica alba
Orobus vernus

—H. N. E.

HIGHLANDS, NEAR GRANTHAM.

In the first week of January my garden was enlivened by *Jasminum (nudiflorum, as I suppose, the yellow flowers appearing before the foliage), *Virginian Stock, Laurustinus,

*Antirrhinums; Primroses, the sulphur, red, and crimson varieties; Chrysanthemums, various colours; *Wallflowers, Heath (the pink herbaceous), Hepaticas, single pink and blue varieties; Acouite, yellow; Cowslip, yellow, and varieties; *Viola cornuta; *Roses, monthly, *La Brillante, *Auguste Mie; Pulmonaria. Those to which an asterisk is prefixed were flowering throughout the greater part of December.

In the fourth week of January I had the Hellebore or Christmas Rose, Snowdrop, Arabis albida, garden varieties of Daisy, and the yellow-striped Crocus.

By the second week of February I had Hepaticas, the double blue and pink; Wood Strawberry in flower; Crocus, white, mauve, and Drap d'Or; Hyacinth, white or Roman. In the third and fourth weeks of February:—Mezereon, Hound's-tongue, or Cynoglossum, Aubrietia, and Polyanthus.

March, owing to its severity, added little to the list; it rather indeed, diminished it. The Roses, the Chrysanthemums, the Antirrhinums, Laurustinus, and Wallflowers, were cut off, and others arrested in their growth. It produced, however, the blossoms of the Almond, Apricot, and Peach, numerous Hyacinths, and the pale yellow Van Thol Tulip.

These all grow on the slope of the high table land between Grantham and Stamford, the highest table land in England, according to the trigonometrical survey, notwithstanding that the prejudices of some have led them to speak of Lincolnshire as consisting only of fens, marshes, and bogs. My garden, however, is greatly sheltered by evergreens, and the minimum temperature in it is usually from 1° to 3° higher on the average of a week than in the vicinity of London, as registered in The Journal of Horticulture. The soil is generally loamy, and filled with small fragments of magnesian limestone, the rock being only from 3 to 5 or 6 feet below the surface. The soil of the flower-beds is, of course, more of an artificial character, having had various fertilising substances from time to time thrown upon it.—Philokepos.

ACKLAM HALL, MIDDLESBOROUGH-ON-TEES.

March	6.	Apricots, Peaches, partially in bloom
„	8.	Variegated Daisy Lungwort Elm White Dead Nettle

LEAFING OF THE OAK AND ASH.

I quite agree with you concerning the leafing of the Oak and Ash. I have always found the Oak some days earlier. I take my observations from the same trees yearly where the trees are growing together. This has been the case for ten years. Unfortunately I have not the former six years' register, but I state the time of budding and leafing for the last four years.

	1864.	1865.	1866.	1867.
Oak in bud	Apr. 12th. ..	Apr. 16th. ..	Apr. 18th. ..	May 7th.
Oak in leaf	May 5th. ..	May 7th. ..	May 26th. ..	May 10th.
Ash in bud	Apr. 29th. ..	Apr. 12th. ..	May 10th. ..	May 29th.
Ash in leaf	May 16th. ..	May 20th. ..	May 29th. ..	June 5th.

I saw it stated a few weeks ago, that the Ash and Oak always come into leaf simultaneously. I think locality must have something to do with the trees from which that conclusion was derived.—R. Hawkins, *Sunderland.*

Manchester Horticultural Exhibition.—We are informed that the money taken at the gates in half-crowns and shillings will more than cover expenses; but beyond this 250 new two-guinea subscribers have been obtained, and there is no doubt but that a very large number of these will continue members, thus contributing to the permanent good of the Society. £500 obtained by extension of membership is of very much more importance than the same amount received for entrance to the Show.

DUTY-FREE TOBACCO.

For fumigating-purposes, I think an admixture of Cayenne pepper would be better than sulphur, and protect the revenue at least equally well.—G. S.

[We think so too. If sulphur is peremptorily required to be mixed with tobacco duty-free for gardening purposes, it will prevent its being employed for fumigating.]

JOTTINGS ABOUT FLOWER GARDENING.

There is often some difficulty in arranging plants in flower gardens, and even after many years' practice the task of arrangement is not always satisfactorily completed without much mental balancing of the plants employed. For instance, should we plant a flower garden of eighteen or twenty-four beds with a variety of colours, in all probability recourse will be had to Pelargoniums with variously coloured foliage. Now, here arises a difficulty. If Flower of the Day, or any of the varieties of which it may be taken as a representative, be employed, the colour of the leaves and that of the flowers will cause perplexity at once, as one or the other will not come in well in forming a proper arrangement with the Tom Thumb and the Nosegay sections.

If, on the contrary, regard is paid only to the colour of the flowers without reference to that of the leaves, the matter is more easily settled. Were I confined to one class or section of Pelargoniums in order to produce a pleasing result in a moderate-sized flower garden, I would decidedly choose the Nosegay varieties, for these offer a great variety of colours; still their foliage in general partakes more or less of a dark green hue, especially when viewed from a short distance; and I hold that a flower garden is seen to most advantage from a moderate distance if it is of some extent, has pleasing surroundings, and is of an appropriate form for displaying to advantage the living picture within. Where flower gardens are placed close to mansions with terraces where architectural embellishments are largely employed, from the architect studying only the display of his professional talent very often when the gardening artist has to perform his part towards the adornment of the residence, he is embarrassed by the massive surroundings.

I have often found a more pleasing effect produced in a flower garden by principally employing the Nosegay Pelargoniums, along with Calceolarias and two or three of the most distinct and compact-growing Verbenas, than when I availed myself of any of the light and Variegated bedding Pelargoniums. Between twelve and sixteen years ago I often encountered a similar difficulty in respect to the tartan-looking varieties of Verbenas which were then planted. Examined individually they may have been pretty, but no frame to the picture, however refreshing to look upon of itself, could compensate for, or cure the muddy appearance which many of them presented to a person at 40 or 50 yards away.

No colour can show off flowers to greater advantage than green, which affords relief to the eye, and a pleasing contrast to the colours of most the plants now used so extensively in flower gardens.

When I have wished to produce effect by the foliage, and not by the flowers, I have frequently never permitted Flower of the Day and similar Variegated Pelargoniums to flower, cutting off the blooms as soon as they appeared. Indeed, one of the most effective ribbon-borders I ever had owed its beauty entirely to the foliage. In it I had Flower of the Day and Golden Chain, with between the two a row of Perilla nankinensis, always kept to the proper height. Golden Chain was next the grass.

What I said respecting standard sorts and former favourites may apply with more or less force to Mrs. Pollock and similar beautiful varieties. If there were a greater contrast between their foliage and flowers, to what advantage could they be employed—for instance if any of them had flowers of the colour of Christine instead of red, salmon or flesh-coloured ones, which, being borne above such a glossy leaf-surface of rainbow hues, greatly diminish the effect, especially when seen from the distance of only a few yards. I never saw Mrs. Pollock look better than in a low-roofed greenhouse, where the range of vision was limited, and where all the flower-stems were removed. In

a partially shaded house, and a rather moist atmosphere, this variety is seen to great advantage; but in the open garden in the sun, particularly where the soil and subsoil are both dry and gravelly, the whole of the Mrs. Pollock class are liable to have their leaves browned. Such is the effect of soil and situation, that in one place they are not satisfactory, except in well-prepared borders and beds, whilst in others they grow as freely as Tom Thumb; but after all will they ever prove so effective as the Nosegays, when seen from a distance of, say, 40 or 50 yards?—G. Dawson.

ROYAL BOTANIC SOCIETY'S SHOW.—June 19.

It has not fallen to my lot to witness many of the great shows this year; and as this was the only one I am likely to enjoy this season, I was heartily glad to hear it pronounced by several of the most constant *habitues* one of the best. To me the exhibitions here seem not only unsurpassed but unequalled. At the Regent's Park, though no novelty is attempted, no sensational alterations made, yet the scene is ever novel and fresh. The view on entering the tent, although seen a dozen times, is still as striking and as fine as ever; and an exhibitor must feel, however he stands with his competitors, that everything has been done to make his plants look effective.

In endeavouring to give an account of the florists' flowers, I shall begin, as in duty bound, with the Roses. Here amongst the growers for sale were to be found, as usual, the finest flowers. Their stock is so large, that it is only when amateurs approach them in this respect, that they can hope to compete with them. Messrs. Mitchell, Cranston, Paul & Son, and Fraser, were the exhibitors; and the best box in the Exhibition was that shown by Mr. Cranston. These consisted of Pauline Lauszeur, Jean Goujon, Souvenir d'Elise, Madame Willermoz, Marguerite de St. Amand, Abbé Berleze, Madame Furtado, Le Rhone, Madame Julie Daran, Niphetos, Madame Boll, Souvenir d'un Ami, Dr. Andry, a truly grand Rose; Général Jacqueminot, now superseded by some of his progeny; Jules Margottin, Victor Verdier, Senateur Vaisse, Madame Knorr, Mdlle. Emain, Gloire de Dijon, and Maréchal Vaillant. Messrs. Paul & Son had some fine boxes, containing in especially good condition Lord Herbert, Duchesse de Caylus, Joseph Fiala, Alfred Colomb, and Triomphe de Rennes. Mr. Mitchell had some very fine boxes of twenty-five Roses, three trusses of each. They were La Tour de Crouy, too full, and rejected by me long ago for that reason, but here very fine; Alfred Colomb, Maurice Bernardin, Celine Gonod, John Hopper, Pierre Notting, excellent; Charles Lefebvre, still unsurpassed; Le Rhone, Madame Boll, Senateur Vaisse, Anna de Diesbach, Madame Furtado, Gloire de Ducher, Maréchal Suchet, loose; Madame Domage, ditto; Louis Van Houtte, rough; Madame Clemence Joigneaux; Maréchal Niel, fine—it is, by-the-by, a mistake to call this hardy; Charles Margottin, rough; Louise Peyronny; Adolphe Rothschild; Xavier Olibo, crooked on opening; Caroline de Sansal, and Madame Victor Verdier. Messrs. Paul and Son were second with fine flowers, containing amongst others Princesse Marie de Cambridge, Madame Fillion, Beauty of Waltham, Alba Rosea, Olivier Delhomme, François Lacharme, Achille Gonod, Madame V. Verdier, Gloire de Dijon, Xavier Olibo, Comtesse de Chabrillant, Madame Charles Wood, Marguerite de St. Amand, very fine; Pierre Notting; and Alfred Colomb, a very fine Rose. Before leaving the queen of flowers I must notice a truly regal addition, in every sense of the word, to our already numerous favourites, but in a class in which we are very deficient. I allude to Miss Ingram, a Rose raised at the Royal Gardens, Frogmore, by Mr. Ingram, the veteran and accomplished gardener at that truly regal establishment. It is a lovely white Rose with a blush centre, somewhat of the shape of the old Cabbage, perfectly hardy, having withstood the frost of January, which destroyed nearly all the light Roses in that locality. I venture to predict for it a career as an English Rose equal to John Hopper.

I suppose many will consider it rather coming down from Roses to Pansies. All I can say is, that it astonishes me that the Pansy is not more grown. It requires, indeed, as all florists' flowers do, more care than bedding plants; but I am sure the enjoyment of beholding these lovely flowers displaying their beauties in early spring, is worth the trouble. Take Messrs. Downie, Laird, & Laing's collection, which was sent up from Scotland on purpose for this Show. What beauties! The stand contained Mr. J. Graham, Waverley, Vesta, Alice Downie, Miss Carnegie, Yellow Queen, Princess of Wales, Countess of Rosslyn, General Young, Alex. McNab, Mary Lamb, Perfection, Miss Ramsay, Comus, C. W. P. Ramsay, Mary J. White, Alex. Whamond, Village Maid, Lady Lucy Dundas, General Lee, Miss Muir, J. B. Downie, Attraction, Arab, Invincible, Emily Lyall, Miss Watson, Gem, Mrs. Hopkins, Eclat, George Wilson, and Chancellor. Inferior to them in form and substance, but remarkable for their novel colouring, were the Fancy Pansies, consisting of — Oriana, Princess Alice, Colleen Bawn, Earl of Rosslyn, Miss Melville, Cedo Nulli, Jeanette, Maccaroni, Mrs. R. Dean, Belle Lilleoise, Indigo, Striped Queen, and Hugh W. Adair. Mr. Turner, of Slough, had a beautiful stand of Pinks, containing exquisite flowers of Attraction, Beauty of Bath, Lord C. Wellesley, Excellent, Rev. Geo. Jeans, Marion, Device, Charles Waterton, Charles Turner, James Hogg, President, Helen, Cristabel, Blondin, Marguerite, Harlequin, Mary Anne, Prince of Wales, Victory, and Emily. Here is another florists' flower which but few grow in these days of gardening made easy.

Pelargoniums were exhibited in fine condition, but I shall only dwell upon the seedlings, of which there was a large bank, the greater portion being contributed by Mr. Foster, of Clewer Manor. Of these the best were—Sœur de Charité, a bright orange flower, lower petals slightly pencilled, upper petals dark, with bright salmon rose margin; Empress, a salmon rose flower, with a beautiful shade of violet through it, dark blotch, with narrow edge; Joan of Arc, a fine dark flower, reminding one by its name of the first grand march in Pelargoniums, ah! how many years ago, when the old Joan of Arc and Foster's Sylph astonished the world; but what an advance since then! Hermit, carmine lower petals, painted with dark cerise, upper petals black, shaded with dark crimson; Prince Consort, rosy carmine lower petals, medium blotch, the plant of excellent habit, and very free-blooming; and Troubadour, a beautiful salmon-coloured flower, very like Mary Hoyle, but a little more carmine in it, perhaps. Mr. Hoyle had only some yearling plants—Needle Gun, very dark; Patrimony, a large flower of bold appearance; and Miss Hervey, a pretty painted flower. Marksman (Fraser), is sure to make a good market plant, from its habit and profusion of bloom. From what I have seen and heard, the present is likely to be what I do not think last year was—productive of some fine flowers; certainly in last year's group there is nothing so strikingly in advance as Charles Turner and John Hoyle were when they were shown.

There is much more to say, but space fails; and here must end my contribution towards encouraging the growth of florists' flowers by detailing the beauties that shine amongst them.—D., *Deal*.

ROYAL HORTICULTURAL SOCIETY.

Weekly Show, *June 22nd*.—At the Show held this day there was only one exhibitor—namely, Mr. A. Wilkie, gardener, Oak Lodge, Addison Road, Kensington, who took a second prize for a collection of Zonal Pelargoniums, a first prize for a collection of Fuchsias, a first prize for a collection of miscellaneous plants, and an extra prize for another collection of plants, also a first prize for cut flowers. From the gardens of the Society at Chiswick an interesting collection of plants was exhibited, consisting of Raphanus caudatus (the Rat's-tail Radish), Gloxinias, Petunias, Heliotropes, Fuchsias, &c.

HOOPER'S NURSERY, NEW WANDSWORTH.

For evidence that a taste for flowers is rapidly progressing we have only to look around and see what has been done within the last few years; and as regards the neighbourhood of London, it is only necessary to visit Covent Garden Market, and compare the quantity and quality of the supply at present with what it was twenty years ago. If we go towards Clapham, Wandsworth, and Kingston in one direction, to West Drayton in another, to Hornsey in a third, to Norwood, or, in short, if we take any thoroughfare out of London, not only villas but whole streets will be found adorned with a little conservatory or greenhouse attached to each dwelling. In digressing from my immediate subject I take this opportunity of directing attention to the fact, that although some progress has been made in heating by hot water by the tank system, and by gas, nevertheless there is a field open for some ingenious practical gardener to obtain celebrity by devising a simple, economical, and efficacious system of heating the small greenhouses or conservatories attached to dwelling-houses.

Mr. Hooper's nursery is but five minutes' walk from the Clapham Junction station. The grounds are entered from the high road. On the left is the seed-shop, counting-house, &c., and on the right the show-house, containing fine specimens of the following Zonal Pelargoniums:—Beauty, pure white, with small centre spot of rosy salmon, dwarf, compact, and perfect in outline. Conspicuum, carmine salmon, margin white, truss large and compact, rising well above the foliage; abundant bloomer, dwarf habit. Clipper, vivid scarlet, large finely-formed flowers. Dr. Lindley, orange scarlet, clear white eye. Duchess, rosy lake, compact, free. Festoon, centre rose, tinted with delicate blush; flowers of very fine form. Gloire de Nancy, deep rosy carmine, with large and perfectly double flowers. Glow, very large truss, and flowers of fine form and substance; free bloomer, colour rich deep scarlet. Wiltshire Lass, rosy pink, remarkably large flowers and trusses, a valuable variety. Nonsuch, bright salmon, white centre and edges. Rev. H. Dombrain, rich velvety cerise, large well-formed flower and truss, very free. Rosebud, rose, edged with white, well-formed flower.

The main walk from the entrance has a border at each side, 40 yards long and 5 feet wide, planted very tastefully in triangular form with Mrs. Pollock, Lucy Grieve, Lady Cullum, Edward George Henderson, Luna, Goldfinch—the last two

with golden yellow foliage and bronze zones of different shades—and other Zonal and Variegated Pelargoniums; also Calceolarias, Rollisson's Unique Pelargonium, and the newest and best varieties of Verbenas. Mrs. Pollock, Lucy Grieve, and other Pelargoniums were planted out before the severe frost of May, and although they lost a few leaves, they are now growing freely, which will go far to prove that they are not so tender as generally supposed.

In the quarters on each side of the main walk are five acres of nursery stock, consisting of dwarf-trained fruit trees of various sorts, also two large beds of the beautiful Spanish Iris, several beds of border Tulips and other bulbs, Lilies of the Valley, Helleborus niger, and upwards of a thousand Provence Roses well furnished with bloom. The pits contained Camellias and Azaleas, which succeed well placed on a cold bottom. There was also a large collection of Verbenas, mostly the new varieties of 1866. Conspicuous amongst them were Crimson King; Junius, a rich Indian red; Mrs. General Lee, rich magenta, with crimson centre; Rosy Circle, brilliant crimson, tinted with rose, white eye; and Scarlet Nonpareil, soft lake scarlet, with large white eye. Variegated Hollies and other evergreens are propagated extensively in small pots, and in the propagating and other houses are Mrs. Pollock, Lady Cullum, Lucy Grieve, and the other new Zonal and Variegated Pelargoniums. Each cutting is inserted in a thumb-pot, and when rooted (which they are in a week or two with bottom heat), they are shifted into larger pots. I noticed a good Lobelia called Blue King, also Arabis mollis variegata, invaluable for edgings to beds and borders, and very freely increased. The two varieties of Viola cornuta can be seen here.

This nursery has been established only four years; for the last two it has been in the possession of Mr. Hooper, who adds to his stock everything worthy of notice in floriculture.—W. Keane.

VIOLA CORNUTA.

As I wrote to you last year respecting my being disappointed in Viola cornuta, I wish to say a few words now in its favour.

The plants have been in the ground throughout the winter, and are now looking perfectly lovely. From present appearances they will continue to bloom for some weeks. I have a circular bed of about 3 feet in diameter, and it is all covered with beautiful mauve-coloured blossoms, and is not surpassed by anything in my garden. Perhaps it is only equalled in effect by its neighbour bed of Cerastium.

You advised me last season to take cuttings of the Viola. I did so, but they do not bloom so well as the parent plants that have been exposed to the long and severe winter.—A. O., *Exeter*.

GISHURST COMPOUND.

In a wood of nine hundred acres of young Fir trees, only 1, 2, or 3 feet high, I noticed two years ago the presence in numbers of a sort of insect, the name of which I did not know and could not obtain from any one. These insects were then (in 1865), confined to two or three acres, scattered about in the wood in several parcels, and they did some harm, destroying several hundreds of trees. The insects lasted the whole year, notwithstanding the cold and the warm weather.

Last year (1866), I noticed that the insects had much increased, and that they covered twenty or twenty-five acres, also scattered about in the wood in many parcels; and at the end of the year I ascertained that many thousands of trees were destroyed by them.

Finally the Easter of 1867 came, and I saw with terror that, contrary to what had ever been seen in this country, all these insects were still living, although the winter had been very cold and very long, and that the trunks of the trees were literally covered with millions of nests of twenty to thirty eggs each; so that it was to be feared that the whole of the wood might be overwhelmed by them, and millions of trees destroyed.

I tried several applications to kill the insects, but nothing succeeded, or when it really killed the insects it also killed the trees at once. I finally heard of Gishurst compound, and used it in brushing the trunks and dipping the branches. It succeeded admirably, killing immediately the insects without doing any harm to the trees. I determined, although the cost of such work was considerable, to do it all over the twenty or twenty-five acres when it was necessary; but I had nearly done two or three acres, when after some extremely hot days, I was happily prevented continuing the task by the arrival of thousands of small insects, which I think are mealy bugs, and which destroyed in a week all the insects and their nests.—A. B.

CULTIVATION OF THE TOMATO IN COLD FRAMES.

There are some dozen or more varieties, Powell's Early Red we consider the best; it answers well for frame culture.

The experience of the past season has sufficiently shown that we ought not to depend entirely on out-door culture to meet the demand. There may be exceptional cases in favourable localities, but in Scotland generally, from the information I have been able to gather, the Tomato crop may be considered a failure last season.

Where abundance of glass is at disposal, few difficulties attend the profitable cultivation of the Tomato; it will produce abundantly, protected by glass, with or without the aid of artificial heat, if provided with an open exposure. The back wall of a vinery, Peach-house, or orchard-house affords grand scope to its luxuriant growth, from which we sometimes see enormous crops gathered; but in our opinion, cropping in such houses is sometimes carried too far, and we think some restraint should be put on the roots. The necessity of this will at once be manifest when we refer to the gross-feeding nature of the Tomato, and its innumerable rootlets, which spread themselves in all directions, extracting the richer qualities from the soil. To avoid this consumption of what is essential to the proper health and development of the permanent plants, boxes 2 feet square by 8 inches in depth (inside measure), plunged level with the surface and filled with rich soil, would be sufficient accommodation to meet the requirements of the Tomato, with the addition of good waterings of liquid manure from time to time.

In many cases none of the accommodations mentioned are at command, and still the demands for Tomatoes are the same.

Cold frames would assist many out of this difficulty if properly applied. But the question may be urged, Where, in that case, are Pelargoniums, &c., to be grown?—they must be displaced or sacrificed before this can accomplished.

The system we yearly practise with good success is as follows:—In the beginning of February a frame is put in order to receive our first batch of cuttings, early Melons, &c. As soon as the bed is reduced to a proper heat, a sprinkling of Powell's Tomato is sown in a six-inch pot and plunged in the leaves along with the Melons, both getting the same attention on to the time the Tomato requires to be singled out and planted individually in pots 3 inches in diameter. The soil used for this operation has been previously warmed by lying a few days in the hotbed. The plants are returned into heat again, and at the next potting they are shifted into 4½-inch pots, the compost employed being one-third light loam, one-third well-rotted manure, and one-third equal portions sand and leaf mould. The plants are again returned to their old quarters, and are similarly managed for a few weeks more, giving larger shifts when their roots have filled the pots. The last potting ought to take place at the commencement of May, and this time into eight-inch pots, by which time the plants are vigorous and are pointing out their laterals (side shoots). They are again put back to the frame and kept in an active condition till the middle of the month, when they are removed to a dry cool pit, placed on boards, and shaded for a few days until they recover the change.

After-culture.—In the last week of May, the arrangements are completed for their final shift into cold frames in the following manner. A line of boxes is placed at proper distances along both ends, and also the back of the frames, and other lines of boxes are placed running from south to north directly under each rafter. The boxes are plunged level with the surface of the sawdust which covers the bottom. They measure 18 inches long, 15 broad, by 8 deep, and are stiffly filled with a mixture of equal portions of rotten turf and old mushroom-bed dung, chopped well up but not riddled. The plants are next introduced and planted at a distance of 2¾ feet apart along the back and ends, as well as in the boxes placed immediately beneath the rafters. Strong stakes are next placed at convenient distances underneath the rafters to tie the shoots to, making the tops of the stakes press hard against the rafter, while the points are secured in the soil below, which acts as a support, and keeps

them from moving; in like manner stakes are provided for the other plants, to avoid damaging the frames by nailing up the shoots to them. The plants should now be well watered, but ventilated sparingly for a few days, and shaded with mats if the sun is strong. It will now be seen that a considerable space is left vacant between the rows of plants, which will give abundance of room to such plants as Pelargoniums, Fuchsias, Balsams, and the like, the Fuchsias and Balsams being plunged among the sawdust, and the Pelargoniums raised on large pots to a convenient distance from the glass. The frames may thus be well stocked, but not overcrowded, and one finds convenience for many plants that are often neglected.

Training.—Our custom is to allow for each plant one leading shoot, and three on each side, trained fan-shape, which shoots are tied carefully to the upright stakes as they progress, and as soon as each has formed two trusses of flowers, their points are pinched out or back to the eye beyond the last-formed truss, and all other growths are scrupulously cut away. Admit air abundantly throughout all the stages of their growth, but particularly when the flowers begin to expand, until the fruit has formed. As soon as the fruit has attained to the dimensions of Walnuts, the first watering of weak liquid manure is given, at first twice a-week, afterwards in every alternate watering. The eyes left at the last pruning will by this time have grown into shoots; these, and every superfluous growth remaining, should be removed.

After this dressing, if the plants are in a vigorous condition, in a short time they will show themselves very impatient, and if there is still one dormant eye about them it will be forced out, and must be at once cut away. The leaves will also be in vigorous growth, and have expanded to prodigious dimensions, which they may fairly be allowed to do, excepting trimming back any that cover or shade the fruit. As the season advances, the swelling of the fruit will keep pace, and the plants will rapidly extract the moisture from the soil, which necessitates a daily and abundant supply of water, especially in strong sunshine; if the weather prove dull, less will be required.

The subsequent management is merely a repetition of that already given—viz., air abundantly, keep clear of extra growths, trim the leaves that interfere with the fruit, at the same time preserving as many on the plant as possible, tie out the laterals as they advance, sprinkle with pure water overhead after a day's strong sun, and as soon as a general show of colour is visible, discontinue water, and take off the lights, excepting on wet days.

From the above system of treatment we managed to keep up a supply from the end of July until November. with a frame measuring 30 feet long, 10 wide, 4½ high at back wall, and 3 at front wall.—A. Kerr (in *Gardener*).

NEW VARIEGATED PELARGONIUMS AT THE BURY ST. EDMUNDS SHOW.

Permit me to call the attention of your readers to the accompanying letter, which I have received from Mr. John Watson, nurseryman, St. Albans, the raiser of Miss Watson and other fine Tricolor Pelargoniums, proposing sweepstakes of twenty and ten guineas for the best two new Variegated Pelargoniums and the best single new Variegated Pelargonium, to be competed for at the Bury Show:—

"I see that there is a cup of the value of ten guineas offered for the best twelve seedling Variegated Pelargoniums of 1866-67, for which I would be glad to compete; but under the arrangements it is impossible for me to do so, for the simple reason that, as soon as I see a seedling is not likely to be useful I discard it at once. And as to seedling Pelargoniums of this class, I see but little advantage to be derived, either by the public or by private individuals, from exhibiting them in this state, as it is well known among raisers that there is no dependance upon them until their character is established both as to habit and colour.

"The object to be sought is to know who has the best kinds not yet sent out; and the only way to bring out the right kinds is to have a challenge cup, value twenty guineas, to be awarded to the raiser of the best two, and a second cup of the value of ten guineas to the raiser of the one best kind, allowing any raiser to compete for both cups, and no raiser to exhibit less than six plants of each kind. This would plainly show who has the best to send out in the two years to come—1867 and 1868—the plants to be judged according to rules laid down in the gardening papers.

"Now, I shall be willing to subscribe £5 5*s.* towards the above prizes. Will you and your friends contribute the remainder? An appeal through the gardening papers would doubtless be responded to at once, and the desired end would be gained. Of course it is understood that I should be at liberty to compete for both prizes. Let me know as quickly as possible, and I will forward my five guineas by post to you at once.—John Watson."

This spirited challenge deserves the support of your readers. I shall be happy to co-operate in any way—to receive and hold the stakes, and correspond with intending exhibitors. I have accepted Mr. Watson's liberal offer conditionally. If liberally responded to the prizes will be offered; if not, all monies entrusted to me will be promptly returned. I sincerely hope, however, that the challenge will be accepted. Independently of such a competition adding much to the richness of the Bury Show, it would test real merit better than any of the other prizes.

There is much force in Mr. Watson's remarks on the instability of seedlings. However, it is now too late to alter the schedule; but by supporting Mr. Watson's thoroughly practical proposal, growers and the public alike would discover two or three of the very best varieties in existence—a point of the greatest possible moment at the present time, when both are bewildered by hundreds of so-called novelties, either like or inferior to those already in cultivation.—D. T. Fish, *Hardwicke, Bury St. Edmunds, Suffolk.*

PARENTAGE OF CLARKE'S ROSE PINK LORD LYON.

The parentage of Clarke's Rose Pink Lord Lyon, a seedling for forcing, to which a second-class certificate was awarded at the Royal Horticultural Society's Show, is as follows:—

Clarke's Garibaldi is the seed parent of Lord Lyon, Claude is the seed parent of Garibaldi, Anne Boleyn is the seed parent of Claude. The pollen parent was a laced Pink named Sir Robert Grant. Mr. D. Fish counted 110 flower-buds on one plant in my garden on the 8th inst.—James Clarke, *College Street, Bury St. Edmunds.*

TOBACCO TOUCH-PAPER.

"N. E. O." requests me to repeat my mode of making fumigating paper. It is as follows:—

Procure some coarse brown or the coarse blue paper usually employed as the outside wrapping of loaf sugar. Cut the paper into strips about 10 inches or 1 foot wide, and form them into a loose roll, confined so by a piece of string. Now, take an old iron saucepan which is useless for other purposes, and place in it a quarter of a pound of coarse shag tobacco, along with three pints of water. Boil for twenty minutes or so, and then strain the liquor off through an old colander. Return the liquor into the pot along with 2 ozs. of saltpetre, and a pinch or two of flowers of sulphur. As soon as the saltpetre is dissolved and the liquor has again become heated, stand in it the roll of coarse paper, and turn the latter upside down now and then. Continue the pot by the fire to keep the liquid hot till the paper becomes thoroughly saturated, then unroll it so that it may lie flat in a large dish, weighting it down with, say, a couple of pebbles, then pour over it the remainder of the liquor from the saucepan, and let it remain till it is cold. Now, dry the strips of paper in the sun, or by a fire, and to what liquid remains in the dish add double the quantity of water, and syringe it over any tree or plant affected with aphis.

In sick-rooms, or when there is any offensive smell in a sitting-room, a strip of the paper merely lighted and allowed to consume will be found to purify the place like magic, and a quarter of a pound of coarse fresh tobacco distributed evenly over the surface of three pieces of the touch-paper, each about 1 foot long, rolled loosely into the shape of a Pickwick cigar, and kept in that shape by three pins—namely, one at each end, and one in the middle, would prove sufficient to fumigate a small greenhouse for the green fly. When the cigars are to be lighted they can be retained in position by leaning them in small empty flower-pots. Should the tobacco prove too damp to burn freely, light the cigars at bottom instead of at the top. I do not, however, recommend this latter method, as the cigar is apt to burst into a flame, and for the welfare of the plants it should never be allowed to do so. One cigar would be sufficient for a two-light Cucumber or Melon-frame.

Plants too large to be covered by the crinoline contrivance, which has been twice illustrated in these pages, I place in the earth-closet. My latest exploit, only a few days ago, in this way was with two large plants of Coronillas, on the stems and branches of which I observed a few scale insects; a large

Myrtle with a few of another species of scale on the leaves; and two plants of Rollisson's Unique Pelergonium, a favourite sort of mine, though very liable to be attacked by green fly. A cigar in the evening and a good syringing next morning before the sun was allowed to shine upon the plants, have set them free from the pests. The exhausted boiled tobacco should be dried and kept for mild fumigations of delicate plants in flower. —Upwards and Onwards.

PEAR CULTURE.

(*Continued from page* 296.)

Pyramidal Training.—A maiden tree being planted early in autumn, it should be headed back in March to one, or at most two eyes above the place where worked. If, however, it is weak the top should merely be shortened a little, but not so much as to cause the eyes near the ground to break, and in autumn, when established, it must be cut back to one or two eyes above the graft. In spring a strong shoot will push from one or both of the eyes or buds; if there be two shoots, the best is to be retained, and the other removed. That which is retained should be trained upright, and allowed to grow throughout the season untouched as regards pruning.

In autumn the shoot should be cut down to within 13 inches from the ground, cutting above a bud, and not too close to it, for if the winter prove severe the bud next below the cut may be injured: therefore, make the cut not less than a quarter of an inch above the bud intended to furnish the leader, nor more than half an inch above it, and in spring, when the resulting shoot is but a few inches long, the portion left may be cut off closely, in order that the shoot or leader may grow erect. This shoot should be trained upright as a continuation of the stem, and below it other shoots will be produced. These must be under more restraint until the cessation of growth, which will be in September, when the strong should be brought down to the horizontal line, or nearly so, but those that are weak ought to be allowed to remain as they are till they become sufficiently vigorous to be bent down, which will be the case by the autumn or end of summer following that of their production. Although the shoots may not be naturally disposed to form a symmetrical head, much may be done towards securing such by judicious early training. The laterals, if any, which is rare, need not be stopped, unless they interfere with the shoots adjoining, when they may be stopped at the sixth leaf. If this be necessary the tree is sufficiently vigorous to allow of the stopping of the upright when it has grown 13 inches, which should be done before midsummer, or not at all, and unless the tree is exceedingly vigorous, the operation is best deferred until the following year, for the side shoots will be much stronger from the mature than from the immature central shoot or stem.

In November the upright should be pruned 13 inches above the point at which it was last cut; but if very strong, 15 inches, and if weak only 11 inches. This heading-back will cause shoots to push for the second tier of branches. The laterals upon the lower tier of branches should not be stopped in the following summer, as it is hardly possible to have the lower branches too strong; but if the laterals interfere with the shoots above them their points should be taken out at the sixth leaf. When the leader or upright has grown 13 inches its point should be pinched off, but not unless the tree is vigorous; for if weak, it is best to secure the first, second, and third tiers of horizontals being strong and proceeding from the mature wood; as regards those towards the top of the tree, the maturity of the wood is of less consequence. I shall presume that the leader has been pinched at 13 inches above where last headed back. Many shoots will be produced at that height, the uppermost of which is to be trained upright, and allowed to grow during the remainder of the season.

At the winter pruning the upright should be cut back to 13 inches above where it was pinched, and the laterals to within an inch of their base; the side branches, having been depressed and regulated at the previous winter pruning, are not to be shortened unless beyond the bounds essential in forming that cone or pyramid of which I now propose to treat. I shall now dismiss the stem and side branches by simply stating that they are to be reared and originated in future years as in the past, until the height desired be attained, when the leader is to be closely pinched.

The width of a pyramid or cone at its base should be one-third the height of the tree. A tree, therefore, having a height of 6 feet, should measure 2 feet in width at the lower tier of branches. Supposing trees to be planted by the sides of central walks in kitchen gardens in borders not under 4 feet nor exceeding 6 feet in width, the trees in a four-feet-wide border should be a little more than the width of the border apart, or 4½ feet, to allow of access to them on every side; in a five-feet border, 5 feet 9 inches; and in a six-feet border, 7 feet.

I will take it for granted that the border is 4 feet wide, and the trees 4½ feet apart. A tree in such a border will, with two tiers of horizontals from the mature and one from the immature or summer growth, appear as represented in *fig.* 11.

Fig. 11.

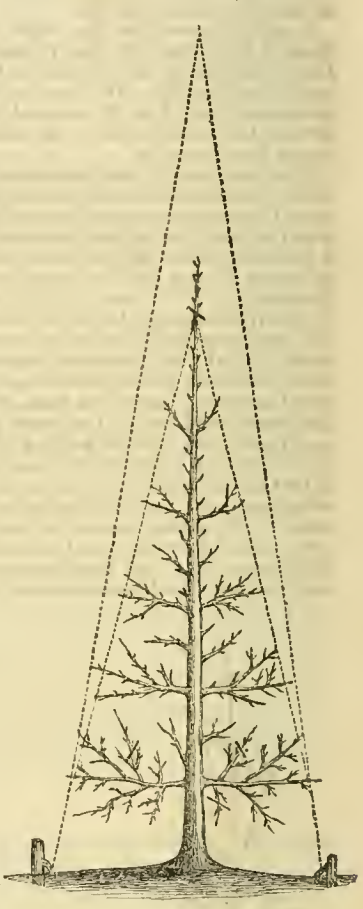

Fig. 12.

The two pegs, *a a*, are intended to be used in tying down the side branches, *b b*, in a horizontal position. A line being strung from *a* to *c*, above the central stem, and 6 feet from the ground, as indicated by the dotted line *a c*, will show the places at which the side branches are to be stopped—namely, where the line crosses them. This stopping should be performed in summer; but as it is most desirable to have the lower branches strong, they should not be stopped until they have exceeded the limits indicated by the dotted lines; and stopping should not be practised until the first tier from the immature wood is taken by stopping the leader.

In the autumn following, the third year of training, the side branches should be cut back, as shown by the bars in *fig.* 11. The knife must in future years not be used except to shorten the central shoot or stem, and to cut the laterals to within a quarter and not more than half an inch of their base. All the side branches should not be first cut close to the dotted lines, for the upper will grow more freely than the lower; the upper, therefore, should be shortened more than the lower—for instance, *b* may be cut at the dotted line, the next tier above at an inch from it, and the third 2 inches, reckoning from the central stem.

The following year the base of the tree should be extended, as shown in *fig.* 12, still taking the line up no higher than before. The dotted lines are intended to show this. Now, the

side shoots, from whatever part produced, are to be stopped at the summer pruning at the lower tier when they reach the dotted line, and so on upwards; and as the side branches will not be numerous enough, they may be allowed to fork; only a proper distance (9 inches), should be allowed between the branches, and none but those required for permanent branches ought to be allowed to extend. Such are necessary to secure and preserve the outline of the pyramid, but all within these must be kept closely pinched. The upper branches will be stronger than the lower; they must, therefore, be restrained by earlier and closer pinching, so as to equalise the sap as much as possible.

It will be seen that the mode of training above recommended is different from that referred to in Vol. XI., page 461. I have acted on the idea that when the cultivator will take the trouble to train his own trees, he should do so in the most handsome form; but the mode of training which I have just described is inapplicable to the majority of trained trees obtained from nurseries.

The great fault of the trees which I have received from nurseries has been their having been originally headed back far too high; the consequence was they were badly furnished with shoots near the base. Sometimes the trees had been headed back at 3 feet from the ground, and were without shoots on one side for a distance of 2 feet from the ground, whilst there were plenty on the other side. This was probably owing to the trees standing so closely together as they do in nursery lines. In other cases the trees were badly furnished with shoots at the base, and those situated there were weak, and consequently the tree could never become so well furnished there as at the upper part, even were the upper branches cut back, and the summer pinching of the shoots produced at the upper part excessive. The case would have been different had the leader been headed back to 12 or 13 inches. They would then have formed trees similar to that represented in *fig.* 13, which is the sort of tree I would recommend, and the only description of tree that ought to be selected. It is only justice to say, that the majority of the trees which I have received from nurseries were well furnished with shoots near their base, in many cases equal to the tree represented by *fig.* 13, and in most little inferior.

Fig. 13.

Fig. 14.

In the case of such trees as those represented in *fig.* 13, 4 or 5 feet in height, formed as shown in *fig.* 12, or bushes of the same height (*fig.* 14), it would be well to head back the leaders at the winter pruning to 13 inches until the height of 6 feet was attained, when the leader should be stopped when it has grown 6 inches, cutting back the after-growth in the autumn to a bud 6 inches above the last stopping, and so on in subsequent years until the required height is attained.

The only other mode of training Pear trees (*fig.* 15), is either the original or a modification of M. Du Breuil's system, the object, it would seem, being to cover the wall or trellis quickly. The trees should be on the Quince stock, maiden plants being eligible for planting. They should be planted 3 feet apart upon a 9-feet, and 2 feet apart upon a 12-feet wall. If planted 3 feet apart they may have three branches, and if at 2 feet two branches, obtained as follows:—

The trees being planted early in autumn may be headed back to two eyes, from which shoots will push. The strongest is to trained upright, and the other cut away. Every encouragement should be given during the summer by watering freely during dry weather, and the tree having made a shoot 3, 4, or 5 feet in length, this should not be cut back in autumn but be brought down to an angle of 45°. In the case of the end trees, the shoot should be taken to the right or left horizontally.

The shoot in the case of all the other trees being brought down to an angle of 45°, will in spring push every eye or bud, and when this is done the branch may be nailed erect, and all the laterals pinched at the sixth leaf, except a strong shoot near the base of the tree, which is to be trained-in to the right or left of the lowest branch, according to the side of the wall which it is required to cover. Neither it nor the leader of the branch must be shortened in summer or autumn, unless one outgrow the other, when the strong may be kept pinched-in during the summer. In autumn they are to be brought down to an angle of 45°, as shown by *fig.* 15, which is intended to represent a 12-feet wall covered in the manner above described. The plan is that of M. Du Breuil, but I have not read his work.

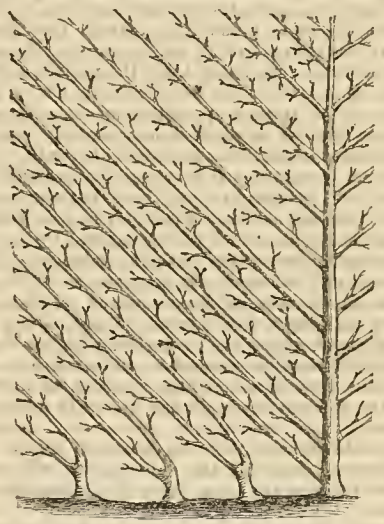

Fig. 15.

The end trees should be planted as many feet, less one, from the end of the wall as the latter is high, but as the shoot will not be of sufficient length the first year to reach to the end of the wall if brought to a horizontal position, it should in the second year be kept at an angle of 45°, a strong leader being insured by closely pinching back the laterals, and in the autumn it may be brought down to the horizontal line, shoot in the following year being trained in diagonally at a foot apart all along the horizontal branch.

Upon a 10-feet wall three branches will be required; the additional branch is to be originated in the same way as the second, and during the third year. The central tree on the wall must be fan-trained. It would be as well to have it and those at the ends of the wall on the Pear stock.

Summer Pruning.—This is the most important operation of fruit-tree culture; for it is evident that if the laterals are not shortened the crop must be small from the vigour of the tree being expended on a quantity of spray, and the fruit must be badly coloured and ripened from its being shaded by the needless crowding of the foliage. It is not the present production only, but the crops of succeeding years that are injured by neglecting to summer-prune; for the crowding of the shoots and foliage prevents the spurs receiving sufficient light and air for their full maturation and perfection. Summer pruning has for its object the maintaining of the tree in order and fertility; it tends to check overluxuriance, prevents the overcrowding of the shoots, secures the formation and perfection of the spurs and fruit-buds, and favours a more full perfection of the fruit.

There is not only some difference of opinion as to the time, but also as to the amount of summer pruning. The time is solely dependant on the season, and the vigour of the trees. The amount of pruning depends on the growth of the trees operated on, for that of some trees is so weak that it may be necessary to encourage it; others are not weak in growth, but are vigorous enough to produce fine fruit; whilst some are so vigorous that the spurs are not nearly so plentiful as the shoots, and the fruit fewer in number than the spurs. Now, to fix any time as the most suitable for summer pruning, and to limit the extent of the pruning to any one rule is impracticable, as it is evident that different trees require different treatment.

All shoots and laterals not required for the extension of the tree, or to fill up vacant space, must be summer-pruned or pinched, whether they spring from the young or old wood; but the leading shoots, or those shoots required for the extension of the tree, should not be pruned, except in the case of pyramidal or bush trees, in which, when the leading shoots make a greater growth than 12 inches, these should have their points pinched at that length. If the trees have covered as much space as is allotted to them, then the leading shoot, and, in fact, all the shoots, should be stopped or pruned in the same manner as the laterals.

Very few trees are so tractable as to produce good crops and require no pruning, or if there are such (as I have had a few instances), the fruit is generally small, and indifferent in quality. In such rare cases, no shortening of the summer shoots being practicable, or at least desirable, any that show themselves should be allowed to grow, and not be stopped until the second week in July, when they may have their points taken off immediately above the sixth leaf, and that is all the pinching they will need.

Trees that are moderately vigorous, or those with shoots not exceeding from 9 to 12 inches in length, should not be pruned until the fourth week in June or first week in July, according to the season, when they should have the points of all the laterals taken out at the sixth leaf, and when they push again, as in all probability they will, take out their points at the third joint above the last stopping, or from the base of the last growth.

Trees that are vigorous, and make shoots when unrestrained of 15 or 18 inches in length, should have the points of the shoots taken off above the fifth leaf, and all growths after the first stopping should be pinched off at the third leaf until the beginning of September, when pinching should cease.

Trees of very strong and rampant growth should be stopped as soon as they have made four leaves, and repeatedly throughout the summer up to September at the third leaf, after the first stopping.

Trees upon the Quince stock may be stopped in all cases one or two joints closer than those on the Pear. The most vigorous shoots will be those at the top of the wall, or where the greatest amount of winter pruning is practised; but, wherever they are, the strongest shoots will of course attain a length fit for pinching sooner, and they ought to be the first stopped or pinched, and in the course of a few days the remaining shoots should be stopped. In all cases, in calculating the number of leaves for stopping, do not count the latent or undeveloped buds at the base of the shoots, of which there are always two or more; only the leaves should be counted, and not the joints or buds.

Any trees with the branches weaker in one part than in another may have the laterals upon the strong branches closely pinched, whilst those upon the weak branches are allowed to grow without stopping until September, when a few inches may be cut from the extremity of each, and these in winter should be cut back to within an inch of their base. In spring a number of shoots will spring from the short stub left. All of them except one should be pinched, that one being left to grow unrestrained until September, when a few inches of its point may be removed, and cut close away at the winter pruning. The shoots pinched throughout the summer should be cut in winter to within 1 inch of their base. We have now a stub two years old, on which fruit-buds are usually produced. It is hardly necessary to add that the short stubby shoots (spurs), with a bunch of leaves, are not to be stopped, for on them fruit-buds form.—G. Abbey.

GYPSUM AS A FERTILISER.

Sulphate of lime, popularly called gypsum, or plaster of Paris, is, in many portions of America, the mineral manure in most general use. As found in the refuse of salt-works, it acquired a local celebrity in some parts of Europe several centuries ago, but the employment of the pulverised rock for agricultural purposes only dates back to about the period of the American Revolution.

Gypsum is a compound of 41.5 parts lime with 58.5 parts sulphuric acid; in its natural state it also contains about twenty per cent. of water.

It is very sparingly soluble in water, requiring 460 grains of water to dissolve a grain of gypsum. This lack of ready solubility would at first thought be considered as objectionable to its use, but really it is a most beneficial property; for if it were dissolved as easily as salt, its benefit to the plant would not be so lasting, and it would require frequent applications to make it productive of much good. Besides this, any mineral salt, although it may be absolutely essential to the growth of the plant, if furnished in too great abundance acts as a poison rather than as food. Now as plants only take in earthy matter when in a state of solution, it is evident that a substance which will afford a lasting rather than an extensive supply will be most advantageous.

The manner in which gypsum acts to increase the productiveness of our fields is a subject on which there have been more discussion and controversy than any other connected with agricultural chemistry; indeed, there have hardly been two writers who have advocated the same theory respecting it. Davy regarded it simply as an essential constituent of the plant, and held that it was not decomposed, but that it entered the plant as gypsum. Liebig holds that its chief use is to fix the ammonia of the air. According to his theory, a double decomposition is effected in the sulphate of lime and the carbonate of ammonia, sulphate of ammonia and carbonate of lime being the result of this decomposition. Hedwig compares the action of gypsum on the food of the plant to the action of the saliva and gastric juice on the food of the animal. That gypsum thrown into stagnant water that contains vegetable and animal substances in a state of decomposition, will cause the production of sulphureted hydrogen, and will also produce a more rapid decay of the vegetable and animal tissues, has often been noticed. To effect this result, it is evident that the sulphuric acid must be decomposed; the oxygen uniting with the carbon of the organic matter to form carbonic acid, and the sulphate combining with the hydrogen.

To apply gypsum with a certainty of producing the best results, requires more theoretical and practical knowledge than does the employment of most manures. Composts, and the solid and liquid excrements of animals, can seldom be used without benefit, whatever be the soil in which they are placed, or the crop it is intended to produce. They are, in a manner, universal fertilisers, from the fact that they contain the essential food of almost every plant. But with gypsum the case is very different. Indeed experience has proved that gypsum of itself is quite inadequate to produce fertility, and that it is only when it acts in conjunction with vegetable manures that its value is most apparent. It is also true that the longer it is used the smaller are the number of crops which are deemed benefited by its application.

It is now well settled that it promotes the formation of woody fibre and adds to the luxuriance of foliage, and that it protracts the period of the growth of the plant, or in other words, delays the time of its maturity. Dust gypsum on half the area of a clover field and the following distinctive results will ordinarily be observed: The leaves will be longer and of darker colour, the stalks more hardy and consequently less liable to lodge, and the period of blossoming will be delayed several days; the number of flowers being comparatively smaller than in that part of the field not so treated.

Now all these results are desirable in the production of clover; particularly are they so when sheep-growers bear testimony to the statement that sheep manifest a preference for, and eat with greater avidity, the clover raised under such circumstances.

On other crops, however, when the object is to produce seeds or fruits, rather than stalks and foliage, the use of this substance would not be desirable; particularly would this be the case where an early harvest is desired. Thus, the use of gypsum has been objected to in the cultivation of Strawberries, for the reason that it tended to the production of Strawberry hay rather than berries.

Too large an amount of it applied to Potatoes, either in the hill or as a top-dressing, has been found to produce a luxuriant growth of tops and comparatively small tubers; but a small quantity placed in the hill or on the sprouts when they are first breaking through the soil, has been found to be highly

beneficial. For the production of Peas and Beans, probably from the large amount of sulphur they require, the use of gypsum is justly celebrated both for improving the quality and increasing the quantity of the product; the same is also true in relation to the culture of the Turnip.—(*Prairie Farmer.*)

THE NEW PEAS.

The Fruit and Vegetable Committee of the Royal Horticultural Society has at last gone thoroughly into the question of the new Peas—a question upon which so much has been written, and so many conflicting statements have been made. No better opportunity could have been found of coming to a satisfactory conclusion on the subject, the trials at Chiswick having this season been in every way most successful, and all the varieties being produced in their best condition.

As regards Dillistone's Early, Carter's First Crop, Sutton's Ringleader, and Veitch's Early, there is no shadow of doubt as to their being all perfectly identical. They bloomed on the same day, or within a day of each other, slatted on the same day, and were fit to gather on the same day. It is a remarkable fact, that some samples of Dillistone's Early, which were obtained from Mr. Dillistone himself, proved to be a spurious and badly mixed stock, resembling Sangster's No. 1, and this will in some measure account for a great deal of the confusion and counter statements that have been made in the discussions relative to this Pea. How such a circumstance has arisen it is for Mr. Dillistone to say, and it is due to the public that some explanation should be given. Some years ago, when this variety was first introduced, it was received perfectly true from a wholesale London house, which was supplied with it by Mr. Dillistone, and singularly enough the sample sent by Mr. Dillistone himself was false. On the representation being made, the following year he sent it perfectly true. If, therefore, any confusion has arisen respecting his Pea, and if in any instances it has been spoken of in depreciating terms, Mr. Dillistone has himself to thank for it.

Dickson's First and Best is a taller grower and produces more haulm than the true Dillistone's, and proves to be a first-class stock of true Sangster's No. 1.

Taber's Perfection is rather stronger in the haulm, and somewhat later by a day or two in filling than Sangster's No. 1.

Young's No. 1 is a first early Pea, 4 feet high, producing more haulm, and about as early as Sangster's No. 1. The ripe seed of last year is rather darker, having a pale olive tinge.

Carter's Improved Emperor is an excellent free-bearing Pea, and is a fine stock of true Sangster's No. 1.

Washington is the same as true Early Emperor.

Carpenter's Express appears to be a run-out mixed stock of early Peas; and the same remark is applicable to Hooper's Early.

London Conqueror is an indifferent second early Pea.

Stanstead No. 1 is identical with Essex Rival; and Essex Rival is one of those pale-podded second or third early Peas, of the class of the old Ringwood Marrow.

Stuart & Mein's Improved No. 1 is identical with Dickson's Favourite, as is also Taber's No. 68.

Sudbury A1 is a white wrinkled Pea, 9 inches to a foot high, and about as early as Sangster's No. 1. This is an excellent Pea.

Dwarf Waterloo is another dwarf Pea, 9 inches to a foot high, a great bearer, producing a fine large pod nearly if not quite as large as the old Waterloo or Victoria, and earlier than Bishop's Long-podded.

Sutton's Long-podded Tom Thumb is wonderfully like the old Spanish Dwarf.

Carter's Improved Tom Thumb is not considered any improvement on the old Tom Thumb.

Mr. Laxton, of Stamford, has been successful in raising some varieties which will prove of high merit, when their characters become fixed. As yet they appear not to have been sufficiently long grown. They were obtained by crossing Laxton's Prolific with Advancer, and it has been found that where these crosses are made the produce from them assume various forms, and it takes two or even three seasons before a permanent character is fixed; and this is done by very close selection. This was so in the case of Dr. Maclean's many seedlings. When they were first raised, they assumed many forms, and for the first two or three years, even from closely selected seed, more than one variety may have been obtained. We look forward with much interest to see more of Mr. Laxton's novelties, and especially that named Alpha, which is an early wrinkled Pea with an immense pod, and as early as Dillistone's. If this keep its present character it will be a treasure.

THE WARATAH, OR NATIVE TULIP TREE OF NEW SOUTH WALES.

The flower called by the aborigines "Waratah," and "Native Tulip" by the colonists of New South Wales, is considered the most beautiful vegetable production indigenous to the colony, and is produced from a stiff, erect and rigid shrub, having the leaves of a hard woody texture, marking the Proteads, to which order the Waratah (Telopea speciosissima, R. Br.), belongs. The leaves are oblong, more or less unequally toothed, and from 4 to 6 or 8 inches in length; dark green, but when just expanding, of a dark red colour. The fruit is a pod containing many winged seeds. The Waratah is indigenous to, and grows luxuriantly and in abundance in the vicinity of Sydney, and other parts of New South Wales, and when first described by botanists was classed with a genus now known as Grevillea, named Embothrium speciosissimum, and figured under that name in Smith's "New Holland Plants," and in Curtis's "Botanical Magazine" (edited by Dr. Sims). It afterwards formed a new genus, called Telopea, derived from telopas (seen at a distance), from its bright crimson blossoms being discernible far off; and those who have had an opportunity of seeing this plant in flower, either wild or cultivated, will readily admit the correctness of this name.

There are some peculiarities of its natural habits and reproduction worthy of notice. The first year the Waratah blossoms it throws out from two to four shoots from each flower-head; in the second year only two, and in subsequent years only one, or more rarely two. To ascertain the way these shoots are produced, it is necessary to procure a flower-head, full-blown or just fading, and on looking closely among the flowers, from one to two or four young shoots will be observed just developing themselves; and these will form the branches of the following year, from each of which a flower-head will most likely be produced. A knowledge of this fact will explain why the plucking of the flowers destroys the new branch, injuring its natural development, keeping the shrub stunted in growth, and preventing its flowering in the ensuing year. The Waratah produces seeds every second year. A tree growing in a garden at Hunter's Hill, in the vicinity of Sydney, five years old, and 10 feet high, produced in 1864 as many as twenty fine heads of flowers at one time, forming a gorgeous sight; and in a tree growing in the Botanic Gardens at Sydney, I observed in the spring of 1865, from one flowering branch produced in the previous year, three stems, each of which was crowned by a magnificent full-blown flower-head.

When a Waratah tree grows in a dense thicket of shrubs, or among creepers by the side of a wall, in the shade, it runs up to a great elevation, a tall slender shrub, seeking the sun's rays; and to obtain light and air previous to developing its blossoms, in several instances, when so situated, the plants have been seen to attain the height of from 10 to 12 feet, or even 15 feet, and then flowering for the first time. In suitable situations, in their wild state, they usually flower when about 4 to 6 feet high, and when at that time stripped of their blossoms, they become stunted, devoid of beauty, and so remain until suckers are thrown up from the roots, by which flowering branches are reproduced. I have also observed that the Rice-paper plant (Tetrapanax papyriferum, C. Koch), only produces branches from the flowering stem; in order to prove it I removed all the panicles of flowers from a young tree flowering for the first time; the result was that the main stem increased in height and developed a new canopy of fine foliage, but no lateral branches were produced as obtained with those permitted to flower as usual. Those desirous of growing the Waratah in perfection, should not permit a flower to be gathered or otherwise destroyed. Many who are aware of the habit of this highly ornamental plant, have some magnificent specimens in their gardens, attracting attention by their rich and brilliant mass of bright crimson blossoms.

The Waratah thrives in a poor sandy soil, well exposed to light and air. The usual time of flowering is in September, (the early spring in New South Wales), and it continues for nearly two months. There are two kinds of flowers,—one the normal state, of a deep, rich crimson, calyx segments tipped

with white. The blossoms when just expanding are of a delicate light pink, a rose colour, gradually changing to a more or less deep crimson hue.—Dr. G. Bennet (in *Journal of Botany*).

NOTES AND GLEANINGS.

The third Great Exhibition of Roses and Congress of Rosarians will this year be held as usual at Brie-Comte-Robert (Seine et Marne). It will commence on the 14th of July, and last for the two following days. Brie-Comte-Robert is the centre of the greatest Rose-growing district of France, and the Exhibition may fairly be expected to be a very fine one, which all English horticulturists who are at the time in Paris should endeavour to see.

—— Exhibitions taking place in the month of July are announced by the following Floral and Horticultural Societies :—

July	1st, 2nd	St. Ann's Nottingham.
„	2nd	Royal Horticultural Rose Show.
„	„	Erewash Valley.
„	„	Wakefield.
„	3rd	Royal Botanic of London.
„	4th	Alton.
„	„	Spalding.
„	4th, 5th	Birmingham Rose Show.
„	5th	Louth.
„	9th	West of England Rose Show.
„	17th	Loughborough.
„	30th	Buckingham.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Special attention must at once be directed to those crops which are to afford the chief supply during the coming winter and spring, planting out *Celery* in its various stages, *Broccoli*, *Cauliflowers*, *Brussels Sprouts*, *Savoys*, *Kale*, &c. The ground from which early *Peas*, early *Potatoes*, early *Beans*, and *Winter Spinach* have been cleared will be suitable for this purpose. Exhausted Strawberry-beds dug after the fruit is gathered, will be excellent as a change for the better Broccolis and Cauliflowers. Deep digging and heavy manuring must be resorted to in all these cases, more especially for the Celery, which cannot be grown tender and crisp without manure and moisture. See that nothing is delayed at this period having a bearing on the supply of the table throughout the coming winter. To this end an extra labourer should be employed by those overpowered by spring business.

FRUIT GARDEN.

The foreright shoots of espalier fruit trees should now be shortened, precisely as directed to be done last week in the case of wall trees. This is the most essential step in a system of pruning, by which those trees may be made to bear from the stem almost to the extremities of the branches. The utility of espaliers, particularly as regards many of the new varieties of Pears, is unquestionable, and the best and cheapest mode of constructing and maintaining their supports deserves consideration. It is now a good time to shorten the shoots of dwarf trees. These trees may be well regulated and judiciously cut within their assigned limits at the winter pruning, but an abundant supply of shoots instead of fruit is the usual result unless the summer pruning is properly attended to. Let a vigorous shoot go on untouched till winter, then cut it back to a few buds, and the general consequence will be the production of three similarly fruitless shoots in the following season, whereas, by shortening such a shoot at the present time, the formation of fruit-buds is almost certain. Therefore, with the exception of some that may be required to fill vacancies, all the shoots of the dwarf-trained Apple, Pear, Plum, and Cherry trees should now be more or less shortened. One-third of their length may be taken off. Those who understand fully the immense importance of thoroughly ripening the wood of all wall trees and espaliers, will pay some attention early in summer to thorough thinning and training. Who can expect Peaches to ripen perfectly when the young wood is dangling from the wall until August?

FLOWER GARDEN.

As soon as the leaves of Tulips, Hyacinths, Narcissuses, &c., have begun to show signs of decay, the bulbs should be at once taken up and placed in an airy situation to dry, and the bed in which they have been growing should have a good soaking of water if they are very dry, and then be dug and replanted immediately. The earliest-planted beds should be kept well watered if the weather be dry. Fill up all vacancies, and cut off dead flowers from Pæonies, Rockets, &c. Sow Brompton Stocks for the last time this year, also Ten-week Stocks for next year. Transplant Sweet Williams and other biennials that are now ready. Hoe and rake borders, and sweep and clean as often as required. Tying-up will be the order of the day generally, all is confusion unless flowers are well staked. A thorough thinning of the shoots of various herbaceous plants should take place previous to the general staking period. A mixed bed will never look well in which gross and overgrown plants infringe on the rights of their weaker but more graceful neighbours. The Ranunculus-beds after blooming, when the grass begins to assume a yellow tinge, ought, if possible, to be protected from rain, as the Ranunculus is extremely apt to emit fresh fibres, and when that is the case, if no worse consequences result, to say the least the next year's bloom is much deteriorated. The seedlings should also be carefully taken up and gradually dried. The main crop of Pink-pipings may now be put in; with common care not one in twenty ought to fail.

GREENHOUSE AND CONSERVATORY.

Many of the plants in the conservatory will, in a majority of cases, be set out of doors; also the principal part of the New Holland plants may be placed in a shady situation in the open air, where they will mature and ripen their growth. In this hardened state they will be much better fitted for winter confinement. The wood of greenhouse plants matured in the open air is less likely to suffer from damp or long confinement than that which has been produced during summer under glass. The juices are much better elaborated; the young wood altogether assumes a firmer and closer texture, and the foliage a more persistent character. These truths are obvious to most growers. Care must be taken that the plants are thoroughly attended to with water, and the worms kept out. Good depths of cinder ashes are efficient for this purpose, yet even these should be lime-watered occasionally. No drainage can be long complete in pots or tubs if liable to the inroads of the earthworm from beneath. Let every attention be paid to young stock of Correas, Epacrises, Polygalas, Ericas, Chorozemas, &c., as regards thorough watering, stopping the gross shoots, and giving them sufficient room, with a free circulation of air, if in-doors. Such of them as are intended for winter flowering should not be shifted after this time. If any Achimenes remain in a state of rest, they may be potted for a late display. Cinerarias from seed should be put into single pots as soon as large enough, and suckers may be taken from the old plants and nursed in a similar way. All Cactaceæ exhausted with flowering should have the old and withered shoots cut completely away, receive liquid manure, and have every encouragement to rapid growth. Pelargoniums should be cut down in due time, before thoroughly exhausted, and cuttings made. The plants should be suffered to become dry in their pots before cutting-in, to prevent bleeding, which exhausts them much. They may be laid on their sides for a week after cutting, if out of doors, to prevent them from becoming wet, and when the young bud has fairly shown itself, they may be disrooted. Put out cuttings of hybrid Roses if firm, and let Chrysanthemums have every attention.

STOVE.

Many of the plants which have been excited, and which are coming into flower, such as Clerodendrons, Gardenias, &c., may be gradually exposed to a lower temperature until they bear with impunity the temperature of the greenhouse, when they may remain some time in flower. When they are done flowering they may be laid upon their sides and kept in a comparatively dry state during the winter, or until they are excited in early spring. Some of the stronger-growing stock, such as Poinsettias, Eranthemums, &c., may be stopped occasionally, in order to keep them bushy, also to produce a degree of succession in the order of their flowering. Attend well to the Euphorbias for winter flowering, more especially the E. jacquiniæflora; a gayer plant does not exist if well grown. They delight in one half fibrous and gritty heath soil, and the other half porous materials, such as charcoal, pounded crocks, small gravel, &c., and the drainage should nearly equal that for Orchids. Clear and weak liquid manure may be given them.—W. Keane.

DOINGS OF THE LAST WEEK.

Until Saturday we had a dull, cheerless week, without a sight of the sun; but now a rising barometer and the dispersion of the hazy clouds give promise of a chance for hay-

making, and a better warming of the ground than it has hitherto received, after which we may surface-stir and pulverise as much as we may. It should not be forgotten that, early in summer, whilst surface-stirring the ground helps to prevent heat and moisture from escaping, it also assists in keeping heat from entering. In sunny days in June we have sometimes found 3° or 4° difference in the temperature at 3 inches below the surface of a hard gravel path and that of earth stirred at the surface, but equally exposed, and in favour of the hard gravel. In the case of tender plants in the flower garden, where the earth temperature is a matter of importance, we have sometimes deferred a little the surface-hoeing of the ground, convinced that though the breaking of the crust to let air into the soil would do good to the plants, it would do more good still if the firm surface had previously been well heated.

KITCHEN GARDEN.

The work was to a great extent a repetition of that of last week as respects surface-hoeing, watering Cauliflowers, Peas, and Beans, pricking out, and thinning Onions, Parsnips, and Carrots. Sowed a bed of the latter for pulling young, also Lettuces and Turnips. Two matters we may notice: For six weeks or two months we had in a Strawberry-pit a rat visit, which annoyed us considerably, as neither poison nor traps would dispose of him or them; but at length a huge rat was trapped. He must have managed to find his way in and out by the openings for ventilation. He did much more mischief by what he cut off and left than what he actually devoured. Even a rat, however, may be blamed for what he does not do. On the morning he was caught we noticed that about a pint of pods had been pulled and partly eaten from a fine row of Tom Thumb Peas at the foot of a wall, and the same rat was blamed for that as well as the Strawberries. Fearing, however, he might have accomplices, we gathered enough for a good dish of the most forward of the Peas, and we were glad we did so, as the next morning from a peck to two pecks were spread along the ground, some of the pods opened and gnawed, and a good many that had Peas not half grown were untouched. This was done though several traps had been carefully set close to the Peas; but for the injury he does we can hardly help admiring the rat, owing to the cunning, the wisdom, perseverance, and forethought which he frequently exhibits. Unless when very hungry or hard pressed, he will not go near a trap or a bait so long as the smell of the human hand will linger near it. Some time ago we detailed how we caught, tarred, and feathered a rat, and for a number of months we were let alone; but now, as the stackyards in the neighbourhood are getting empty, we are threatened with a fresh inroad of an army that will come to no terms of conciliation. They must either be killed or driven away if we wish to enjoy the fruits of our labour.

We have numbers of letters from various parts of the country telling the same tale—that where game is greatly encouraged, where pheasants are fed and reared, there will be sure to be plenty of rats and clouds of sparrows. In a lot of Peas, the garden being more still last Sunday, if one pod was picked by sparrows there was fully a bushel so used, and at a time when every pod was wanted to keep up a regular supply. Under such circumstances the greatest advocates of the feathered tribe need not wonder that we resorted to means to lessen the number of such visitors, even though against our inclination, for we love to see them hopping about and chirruping. One of our favourites, and who seems to like the protection he obtains, is the dishwasher, or water wagtail, one of the most beautiful and useful of British birds, as he picks up the innumerable insects. We thought that the winter had thinned considerably the thrushes and the blackbirds, but as soon as the Cherries and Strawberries are swelling we have whole clouds of them; in fact, without securely netting we never could have fruit of any of these fit for table. What is puzzling and a little irritating is, that whilst we could not leave a Cherry unprotected after it took the second swelling, and long before it was ripe, there are large Cherry trees in meadow orchards within less than a mile of us, close to hamlets, with seemingly nothing to disturb the birds, and there the Cherries will become ripe and scarcely one be nibbled. Last season when, owing to not netting and never firing a gun, scarcely a Pear flower-bud was left on our dwarf trees, at a short distance in village and farm gardens not a bud was touched. The firing of a canister of powder has saved our Pear-buds this season, and the crop consequently will be good. The only trees that suffered from the birds were some early ones that we put some Laurel branches round to protect from the cold; and if we had not removed the branches we would not have had a bud left, as every bird within visiting distance would find out what was beneath these branches, and acted accordingly. On the same principle, if a net is not made secure it will be worse than no netting. The very sight of it sets every thieving bird reconnoitering. We would let them have their share willingly, but when they are satisfied with nothing less than all the crop, it is time to begin to think how we are to be paid for our own labour. Much against our will, we were forced to thin the sparrows a little with potatoes and arsenic beat up together, and put down where no domestic animal or other favourite bird was likely to go near the tempting bait.

FRUIT GARDEN.

Watered some Strawberries, to cause them to finish swelling their fruit in perfection, removed the most of those under glass, and watered trees in pots and Peach and Vine borders with manure water. In going through an orchard-house we noticed that in some bunches of Grapes just set, the little berries, like dust shot, were black at the points, and we feared that some fungus or mildew was paying us a visit, more especially as, owing to the cold and sunless character of the weather, there had been less air given than usual. On closer inspection we found that the dark ugly appearance was owing to the calyces of the flowers clinging to the young fruit, and a gentle application of the hand along the young bunch, and a rather higher temperature, caused the most of them to drop off. A little more heat, and a moister atmosphere when coming into bloom and setting, would have caused the calyx to drop off freely without assistance. Without the slight help given, most likely the berries thus cramped would have failed to have grown or swelled freely. The appearance of these few bunches before being thus acted on, was just as if the points of the berries had been painted with a blue blacking. Notwithstanding the little trouble given, a few of the berries will prove to have been too firmly embraced by the calyx to swell freely afterwards. This appearance took place only on one Vine, and there is more than double enough left, and the manifestation was entirely owing to the want of more heat, to give an additional impetus to vitality to throw off the calyx freely.

Perhaps in no season have there been more complaints of young bunches decaying, shanking-off, or becoming little better than a tendril, from the flowers dropping. When such appearances are not due to the want of reciprocal action between roots and branches, to unripened wood of the previous year, or to bare roots a long way from the surface, they are likely to be produced by a too close and moist atmosphere in the house, and which with many of us is apt to be the case in cold, sunless weather, when we wish to economise fuel, which we must have burnt if we had given much air.

Blotches and scaldings on the leaves are also produced from the same cause, and mildew is likewise to a great extent due to the same fertile source of mischief. Early ventilation, and a little more artificial heat to enable it to be given, would be the best cure for most of these maladies. Painted the pipes in the vinery when pretty cool with flowers of sulphur and water, and to make this paint adhere better, used dissolved soft soap in the water. When the pipes became warm the sulphur and soap smelt rather strongly, and for several nights a little air was left on at the top of the house, even all night, to avoid every possibility of danger. There is no better preventive of mildew, red spider, &c., than keeping a coating of sulphur on the pipes, but it must not be applied to a house where the pipes are hot, without air being given, or it will rust the berries when young. The Black Hamburgh is, perhaps, the most likely to be affected injuriously when in a young state, just out of bloom. Some plants, as Ferns, also suffer from sulphur fumes, especially if the heat in the pipes is above 160°. A little air kept on will make all safe, and the sulphur will be the best antidote to mildew.

ORNAMENTAL DEPARTMENT.

Much has been done in this field of labour, but we have time to advert to only two subjects, in addition to those referred to last week.

With or without bulbs, the flower garden is generally anything but at its best for some weeks after the bedding plants are turned out, and though much may be done with *early annuals*, beds of these, if sown where they are to bloom, prevent due justice and preparation being given to the bedding plants. We have frequently followed a system with early-flowering low-growing annuals, that rendered the flower-beds gay at once, after early bulbs, or without them, and that interfered but little with the welfare of bedding plants in the same beds. The beds were dug and prepared in the usual way, and then were planted in patches, with Nemophilas, Clarkias, &c.

that were either sown in the previous autumn, or in a bed in the following spring, so as to be raised in patches. These patches were far enough apart to permit of the bedding plants being well planted and in their regular places, and the annuals kept up a good appearance of bloom until the bedding plants almost choked them with their advancing growth. Many plants, as Sweet Alyssum, &c., may remain as under-crop or carpeting, and if a few flowers come through the foliage of the bedding plants, it will be an advantage rather than otherwise. If a fine bed of annuals is grown and flowered where sown, the same ground will not do justice to bedding plants, and they will make no great display unless turned out as large plants from pots. The lowest-growing annuals are the best for this early-flowering and partly-carpeting system, and when the annuals are planted out in patches of a good size and a considerable distance apart, every fair chance is given to bedding plants, and the ground is never so much seen after fresh planting.

The second subject is *watering*. The season has been trying to bedding plants turned out early. We did not plant early, and, therefore, lost none from that cause. Some plants, as Amaranthus melancholicus and Iresine, we turned out about the 20th of June, and early enough we found it for the first, though the sun that we have now will make up for all deficiencies. When some of these early-planted bedding plants looked rather badly, they were made much worse in many cases by injudicious watering. When a plant shows signs of distress the water-pail is looked upon as the infallible remedy, when cold rather than dryness is the cause from which they suffer. Would some of our readers just reflect, that the damper they make the soil the colder they make it, they would use water less plentifully. Some of our contemporaries have been telling their readers to soak their bedding plants well, and yet there are complaints that these do not thrive. We should say, that at least up to Saturday we have had no weather that would have warranted giving more water than would just moisten the roots of bedding plants, and the drier the surface of the soil was left all round them the better it would be for them. If freshly planted subjects, whilst the ground was comparatively cold, showed distress at a little bright sunshine, it would be safer to sprinkle the foliage a little instead of deluging the cold soil to insure its being made colder. A very little water at the bottom of each plant is all that has yet been given to our bedding plants, besides the little at planting to settle the earth about the roots, and we would not have given more even had we a river to go to. The plants are as yet all right, and we should not think of deluging the ground with water, or even damping the soil far beyond the extent of the roots, until at least we have had more sun and a higher temperature, that the roots may have warmth as well as moisture.—R. F.

COVENT GARDEN MARKET.—June 26.

All kinds of out-door vegetables are plentiful; and Cherries, Strawberries, and forced fruit are equal to the demand.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Orchard-house Management (*C. P.*).—The direction is "W. W.," Holcombe Vicarage, Wellington, Somerset.

Conifer (*J. F., Cornwall*).—Several pages of our Journal would be occupied if we explained intelligibly and usefully the numerous genera of this natural order. We have a volume preparing which will impart the information, and much more than you mention.

Irrigation (*W. Jackson*).—Stephens's "Practical Irrigator" will suit you.

Mr. Hullett's Chinese Sugar Grass (*Hope Deferred*).—We are sorry that you sowed it, and sorry that it has failed, but we cannot aid you. Be wiser in future.

Greenhouse Stages (*Amateur*).—You must be the best judge of how the stage should be altered to suit the plants. Even now you could not well have the front shelf of the stage lower without lowering your platform in front. We consider the stage a very good one for small or fair-sized plants. If your plants are large you could set them farther apart, and even miss one shelf and use the next. A good-sized pot will stand on a shelf 7½ inches wide. We would not wish a better stage for general purposes. It will hold many small plants, and large ones placed more thinly will have all the light possible. If large plants are chiefly desired, a flat table or a stage with fewer and wider shelves would be better.

Training Cucumbers (*Idem*).—It is well not to keep Cucumbers too long in vineries; but we have grown them well there and early on the floor, on a bed, on a trellis, and standing upright trained to a stout rod, and pretty well stumped in, much in the style that Mr. Rivers adopts with his trees in pots. Cucumbers bear well on that plan, but we will give the best advice when we know the case.

Viola cornuta (*R. S. S.*).—The flowers you enclosed are the true Viola cornuta. It is in many old gardens, and being introduced nearly a century since, it is not surprising that it has been in yours a quarter that period. The sand enclosed is quite suitable for potting-purposes.

Removing Roses in July (*W. M. S.*).—As they must be removed, cut all round each of them at once, at 1 foot distance from the stem, by thrusting down a spade the full depth of its blade. Keep them well watered, and remove in July with the balls of earth as unbroken as possible. If to be removed to a distance, each had better be put into a pot fully large enough to receive the ball. After planting keep them well watered and mulched.

Azalea Cuttings (*Jeremiah*).—The cuttings should be taken from the shoots of the current year, selecting those which are moderately strong. When the wood becomes a little hard, or what is known as half ripe, the points of the shoots should be taken off at a sufficient length for cuttings. Cut below the lowest joint which they may have, remove the leaves from the lower part of the cutting, and for half its length; then insert the cuttings up to the leaves in silver sand. The pots may be plunged in a hotbed of from 70° to 75°, with a shaded and close atmosphere. Azaleas unite the two sexes in the same flower.

Embothrium coccineum and Philesia buxifolia Culture (*F. G.*).—The Embothrium requires to be planted against a wall with a south-west aspect, training it against the wall and keeping the shoots moderately thin, and the forerright shoots well stopped during summer. It does well in a compost of turfy peat and loam, with a free admixture of sand. Philesia buxifolia succeeds in a compost of wet bog soil or peat, and should be kept abundantly supplied with water. Free drainage is essential. It is hardy, and so is the Embothrium. They flower freely when of sufficient age, and are to be kept in order by frequently stopping the irregular growths, up to July, when stopping must be discontinued. They are also very tractable as pot plants, if afforded the protection of a cool house in winter, with abundant light and air at all times. The blooming is dependant on the ripening of the wood, it being necessary to secure a good growth, and to have it well ripened by full exposure to light and air.

Acrophyllum venosum Culture (*Idem*).—This plant requires a light and airy situation in a cool house, to be well supplied with water when growing, and at all times to have the soil moist. A compost of two-thirds sandy peat, and one-third turfy loam, with a free admixture of sand, will grow it well. Good drainage is essential, and not less so are light and air plentifully furnished. The plant should be potted in spring after flowering, and may then be cut in as required, to give it a suitable shape. It is not hardy, but requires a house in winter, from which frost is excluded, otherwise it cannot be kept too cool in winter. It is the better of a cold pit or frame in summer. A work such as you mention is being prepared for publication.

Taking up Tea scented Roses in Winter (*Syntax*).—It is desirable to take up the delicate kinds of Tea-scented Roses in autumn, keeping them cool and dry during the winter, and planting out in spring. They must not be kept so warm in winter as to cause them to grow. Any of the florists advertising in this Journal can supply the Violets you require.

Peas Failing (*Young Gardener*).—We can only account for your Peas failing from your watering them excessively. In fact, you say they are sown in deep trenches, as for Celery, putting in plenty of manure. Peas

like good rich soil, but are impatient of boggy soil, such as your trenches filled with manure would be, the subsoil being a yellow clay. An opening made and filled with manure, and this well mixed with the soil, is excellent for summer crops of Peas, but the trench should be filled up to the level of the surrounding ground. When sown in a trench the plants are apt to become earthed too deeply, and the stems rot or decay when watered, or during wet periods. Such we think is the cause of failure in your case, and we can only recommend you to look to the drainage of the soil. Let it be well drained, and we think that with liberal dressings of manure you may grow Peas well, for it is just such a soil as late crops succeed well in. The warts at the roots are quite natural. You will find them on all plants of the Pea family.

Liquid Manure for Caladiums and Achimenes (*A Constant Reader*).—The best liquid manure that we have tried for these plants, and, indeed, for all plants in pots, is that formed by pouring thirty gallons of rain water over one peck of sheep's dung fresh from the pens, and one peck of soot. Stir the whole well up twice a-day for two or three days, allow the liquid to stand a day or two longer, then stir again, and use it for watering with once or twice a-week. 1 lb. of guano in twenty gallons of water, along with half a peck of soot, will form one of the best liquid manures known.

Covering for Vine-border (*Idem*).—A cheap and effectual covering for Vine-borders is felt well pitched and tarred, and sanded, fastened to a frame formed of slater's laths 2 inches by ¾ inch). A number of such frames, each 6 feet long and 3 wide, can soon be made for covering the border, and are easily moved. A covering of tarpauling is also good.

Muscat Hamburgh Vines Mildewed (*Mr. Gough*).—The bunches should not be syringed but be covered with sulphur; this will check the disease—in fact, cure it. In a few days the sulphur may be washed off by syringing with clear soft water. If you find any difficulty in making the sulphur adhere to the berries, you may slightly syringe the bunches, and then apply the sulphur, washing it off in a few days.

Removing Sweet Williams and Dianthuses (*Rose*).—To make room for bedding plants you may take up the Sweet Williams after they have flowered, also the other Dianthuses, with good balls of earth, giving them a good watering previously, and planting them in an open situation. Shade them for a few days, and afford copious supplies of water until established. They should be planted where they are to bloom.

Rose Cuttings (*Rose*).—Cuttings put in immediately after the first flowering is over, or now, will bloom finely next year. They should be inserted in sand in a cold frame, and kept close and shaded until they begin to grow, when they may be taken up and potted. Continue them in the frame until spring, affording air during mild weather, and protection from frost. In spring they may be planted out where they are to bloom.

Summer-pruning Currant and Gooseberry Bushes (*Idem*).—You may now cut back all the laterals or side shoots to three leaves, and take out the points of the terminal shoots. This will give you finer fruit, and if they push again stop or take out their points in like manner at the third joint or leaf above the last stopping. The last stopping should be done in August.

Propagating Golden Balm (*Idem*).—This plant strikes from cuttings as freely, if not more so, than the white-variegated variety; but is not so constant in its variegation. Cuttings put in now in sand in a cold frame, shaded, and kept close, will soon root, and being protected over the winter in a cool house or frame, will furnish a quantity of cuttings in spring. These will strike freely in a gentle heat. You may take up two or three old plants in autumn, wintering them in a cold frame, and by placing them in heat in spring you will be able to obtain a number of cuttings. These if put in in March, or early in April, in heat, will be fit to plant out at the end of May.

Hardy Fuchsias (*South Hants*).—Most, if not all the kinds of Fuchsias, will succeed in sheltered situations and well-drained soils, with a six-inch covering of dry leaves or litter in winter. The following need no protection, but are better with a covering of decayed leaves—Riccartoni, gracilis, corallina, globosa, microphylla alba rosea, and microphylla grandiflora superba.

Summer-pruning Pear Trees (*T. R. Drake*).—See some notes by Mr. Abbey to-day.

Names of Plants (*F. Fencott*).—It seems to be a Melissa, but not being in flower we cannot be certain. Whatever it is, it is of no particular value. (*D. A. B.*).—Selaginella uncinata, Pilea muscosa. (*A Subscriber*).—Auchusa sempervirens. (*Quintin Read*).—1, Nepeta Mussini; 2, Saxifraga ceratophylla. (*W. R. P.*).—1, Clintonia pulchella; 2, Thalictrum aquilegifolium; 3, Spiræa ariæfolia.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 25th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME FOWL BREEDING THIS SEASON.

I fear that the mortality amongst our young broods this season has been very severe in some localities. Several of my friends here have complained of the serious losses which they have sustained; indeed, my own yard has not escaped a fatal disease which is quite novel to me. I will endeavour to be as minute and particular as to the nature of the complaint and with respect other matters as possible.

My brood stock consists of a fine healthy Black-breasted Red cock, three pullets of my own breeding, and three hens selected from a celebrated yard on the borders of Shropshire (I am informed Shropshire was at one time famed for its excellent breed of Game fowls). These were put early together, and one of the pullets becoming broody in the end of December, I placed nine of her own eggs under her in a warm situation, and as free from intrusion as possible. I am glad to say from these eggs she brought out seven chickens, which were placed as soon as convenient in a room where a fire was occasionally kept. Their food was given frequently, and was varied, consisting of such as boiled eggs chopped and mixed with bread crumbs, bread soaked in milk or ale, potato, pudding, small sound wheat, and grits; indeed, anything that would conduce to their well-doing. They had also shallow boxes containing dry earth often changed, clean fresh water, and, when the ground and weather would allow it, worms were given them. Grass was also given them gathered from the sunniest banks, and where least exposed to the inclement weather. They were also indulged an hour or two each day out of doors in some warm shady place when the weather was favourable; indeed, no effort was spared to raise them, and I am glad to say now, that with the exception of one all are fine, healthy, vigorous birds.

In February, I had two more clutches hatched from the three hens. These were placed in a room devoted entirely to the young broods, and where no fire was kept, but facing the sun. The hens were placed in pens which are ranged longitudinally, and are 2 feet square, each pen having two doors with rounded bars placed 3 inches apart. Clean sweet straw was given them, and fresh supplied when necessary. The floor of the room was covered with dry earth and everything kept scrupulously clean. Feeding and other particulars as before. These all died.

In March I had another clutch from the same hens. These met with the same fate.

In April I obtained a sitting of Game eggs from a friend. These were placed under a broody hen, and at the same time I placed a sitting from my own hens under another hen, and as soon as these were hatched they were taken away a mile from my house, both broods being placed in one room, and every care taken for their well-doing. Strange to say, those from my own hens all died, affected in a similar manner to those before, and those from my friend's are now fine healthy chickens, never having shown the slightest symptoms of the disease.

I will now give you as nearly as possible the particulars of this destructive malady. In some instances all go on well for a fortnight; in other instances the chickens are hurried away in two or three days, the symptoms being (without apparent cause), sudden loss of appetite, violent purging, the motions being of a very acrid glutinous nature, and the vent becoming glued up; the body dry and much attenuated, and then comes the end. I have tried many modes of treatment to save the chickens thus affected but without success, with the exception of two cases. I find warmth and slightly stimulating food the best remedy.

I seldom keep more than a dozen hens, and have only reared one brood of chickens in the same yard before. They have an

unlimited grass run and good water, also a dry soil. I have found that birds by a removal from the country where they were bred, to a distant one have suffered in constitution, and I have also known it to have a contrary effect. For instance, a few years ago I forwarded to a friend in Craven, some forty miles from where I reside, a pen of Game fowls. These birds had been bred in-and-in, and were becoming somewhat small. My friend bred from them, and, singular to say, the produce improved both in bone, size, and stamina. The situation was dry and well sheltered, with good water, and the mineral limestone. It is just possible the hens I have bred with this season have suffered by removal, or they have otherwise had some hidden taint in the constitution.

I have no hesitation in saying, that several of our most choice breeds of poultry have much degenerated in stamina, and to a great extent this deterioration is owing to breeding from stock which has been too freely exhibited, and, consequently, cannot have the health necessary to produce a vigorous progeny.—Yorkshire.

UNPRODUCTIVENESS OF HIGH-PRICED EGGS.

I quite agree with "Veritas," that the sellers of high-priced eggs do themselves more harm than good in supplying eggs that are either stale or insufficiently impregnated. My own experience this season has been somewhat the same as his. About a month ago I sent an order to one of the best poultry establishments for two sittings of eggs. The eggs were received and placed under two proved hens that I had waiting in five days, so that no time was lost. The cost of the two sittings was about 38*s*., all expenses paid; the result, three chicks.

I wrote at once to the house stating the case, and by return of post received a letter expressing regret at my ill-success, but stating that the same number of eggs (twenty-six), had been gathered from the nests that morning, and sent to me, "free of cost." Now, this is what I call liberal and conscientious dealing, and worthy of the imitation of all, and in all trades. I do not feel at liberty to disclose the name of the firm, but will certainly do all I can to recommend it amongst my own friends.

Whilst I am on this subject, I would like the opinion of experienced breeders on this theory expressed by the writer of the above letter, "that unless the birds are well impregnated at the commencement of laying, the whole batch of eggs remain unproductive." Is not this rather far-fetched? I think with "Veritas," it is simply a matter of fresh or stale eggs. I have just had two broods hatched, the one Houdans, in twenty days, the other Crève Cœurs, in between nineteen and twenty days. The eggs were in both cases all laid by my own fowls in one day, and put to hatch at once. I had twenty-five chicks out of the twenty-six eggs. A friend of mine has spent some pounds this season in high-priced eggs, the result has generally been two or three chicks per sitting. Another friend has one cock and twenty-eight hens, all last season's, a mongrel set, but fine birds. He has had about one hundred chicks this month. His losses average ten per cent. on the eggs, and the chicks are healthy and strong.

Some of my friends argue that travelling is detrimental to eggs for hatching. This cannot, I think, hold good with fresh eggs, being perfectly full. A fresh egg cannot be shaken; a stale egg, wasting every day, produces a vacancy, which, of course, gives room for the yolk to be shaken about. My last sitting of last season's, the eggs from London, in the month of August, produced twelve chicks out of thirteen eggs.—A. Le Cheminant, *Foulon Vale, Guernsey*.

I saw in your Journal sittings of Dorking eggs advertised in England, and in March wrote for a sitting, for which I paid, with carriage, 19*s*. They were put immediately on their arrival under a most steady sitting hen, but at the end of the usual period there was not a vestige of a chicken in any of them, and some presented an appearance similar to that of a boiled egg. I am bound to say, however, that from the first sitting of eggs this year from my own birds. I had only one chicken in the lot, and in a second only five. I think, however, where very high prices are paid for eggs, it would be in the interest of dealers, in cases of such total failure, to supply a second sitting—say at half price—not that they should be bound to do so, as, of course, in some cases, they might be exposed to imposition, but where they have reason to believe in the respectability of the party concerned, I think it would be only just to make some allowance of the kind I suggest.—An Irish Subscriber and Sufferer.

MERITS OF HAMBURGHS.

I coincide with all that your correspondent "Toby" says about the Pencilled Hamburgh fowls. If any of the fanciers of the Brahma Pootra, Dorking, or Cochin kinds will keep an accurate account of the quantity of eggs laid in a season, they will find that the Silver-pencilled Hamburghs will throw all the others into the shade. No doubt those fanciers will say the eggs of Hamburghs are small—and they are rather small; but let the eggs for a season be weighed, and a very large balance will then be found on the Hamburgh side.

I well remember one of your correspondents asking, Who ever heard of a Hamburgh fowl laying in the winter? I have had fresh-laid eggs from Hamburgh fowls all through the winter. I have had Silver-pencilled hens laying when nearly naked in the moult, and only stopping for a very short time; whereas my neighbours who have kept the leading kinds they call winter layers have not had an egg, and have come to me for the eggs of my Hamburghs. I have kept all kinds of fowls except the new French ones, and I find that as layers the Hamburghs are the best. Moreover, not one of the four varieties of Hamburghs are such large eaters as most of the large fowls.—E. F. G.

BRIGHTON POULTRY SHOW.

This Show, held in connection with that of the Southern Counties Agricultural Association, commenced on the 24th inst., and will close on the 28th. The entries amounted to about 180 pens of poultry and Pigeons. The following is the prize list:—

Dorkings (Coloured).—First, D. C. Campbell, M.D, Brentwood. Second, J. Clift, Dorking. Highly Commended, C. Cork, New Shoreham, Sussex; J. Lewry, Bolney, Cuckfield. Commended, D. C. Campbell, M.D. *Chickens*.—First, J. Lewry, Bolney, Cuckfield. Second, Messrs. E. & A. Stanford, Ashurst, Hurstpierpoint. Commended, D. C. Campbell, M.D.; Mrs. M. Seamons.

Dorkings (White).—Prize, T. P. Edwards, Lyndhurst, Hants. *Chickens*.—Second, H. Lingwood, Barking, Needham Market, Suffolk.

Game (Black and other Reds).—First, S. Matthew, Stowmarket, Suffolk. Second, S. Dupe, Evercreech, Bath. Highly Commended, H. Gorringe, Southwick Green, Sussex. *Chickens*.—First, J. Jeken, Eltham, Kent. Second, J. H. Rigden, Hove.

Game (Pile, Blue, or Duckwing).—First, S. Matthew. Second, Rev. F. B. Parkes, Rectory, Southwick, Sussex.

Spanish.—First, J. Jenner, Lewes, Sussex. Second, A. Heath, Calne, Wilts. Highly Commended, R. Wright, Holloway Road, London; J. Jenner. Commended, R. Fulton, Deptford. *Chickens*.—First, F. James. Second, J. Jenner.

Cochin-China (Coloured).—First, J. Stephens, Walsall. Second, T. Elam, Southsea, Hants. *Chickens*.—First and Second, F. W. Rust, Hastings.

Cochin-China (White).—First, H. Hobson, Walsall. Second, H. Loe, Isle of Wight.

Brahma Pootras.—First, The Marchioness of Bath, Muntham Court, Worthing. Second, E. Sheerman, Chelmsford. Highly Commended, F. James, Peckham. Commended, E. Sheerman; F. Crook, Forest Hill; Marchioness of Bath. *Chickens*.—First, Mrs. M. Seamons. Second, A. Essery, Kingswood, near Bristol.

Hamburghs (Gold and Silver-pencilled).—First and Second, F. Pittis, jun., Newport, I. W. (Gold and Silver). *Chickens*.—First, H. Pickles, jun., Earby, Skipton, Yorkshire. Second, C. Catt, Brighton (Gold). Commended, C. Havers, The Beacons, Ingatestone, Essex (Silver); C. Catt (Silver).

Hamburghs (Gold and Silver-spangled).—First, withheld. Second, T. Penfold, Newhaven (Silver). *Chickens*.—Prize, H. Pickles, jun.

Polands.—First, D. Mutton, Brighton. Second and Commended, T. P. Edwards.

Game Bantams.—First, F. Pittis, jun. (Duckwings). Second, Rev. G. Raynor, Tonbridge (Black Red). Commended, J. Lamb, Hastings (Black-breasted Red Game). *Chickens*.—Prize, Rev. G. Raynor (Black Red).

Bantams (Any other distinct variety).—*Chickens*.—Second, T. C. Harrison, Beverley Road, Hull (Sebright).

Geese.—First, Mrs. M. Seamons, Hartwell, Aylesbury. Second, Lady M. Macdonald, Woolmer, Liphook, Hants.

Ducks (Aylesbury).—First and Second, Mrs. M. Seamons.

Ducks (Rouen).—First, H. Densett, Pleshey, Chelmsford. Second, F. Parlett, Great Baddow, Chelmsford.

Ducks (Any other distinct variety).—First, W. Stanford, jun., Steyning (Black East Indian). Second, Mrs. H. Wild, East Peckham, Kent (Muscovy).

Turkeys.—First, Marchioness of Bath. Second, Lady M. Macdonald.

PIGEONS.

Carriers.—First, H. Yardley, Birmingham. Second, R. Fulton. Highly Commended, Messrs. Watson, Hove; R. Fulton.

Tumblers (Almond).—First, R. Fulton. Second, F. Else, Westbourne Grove, Bayswater.

Tumblers (Other sorts).—First and Commended, R. Fulton (Short Face). Second, H. Yardley.

Pouters.—First and Second, R. Fulton. Commended, H. Yardley.

Runts.—Prize, H. Yardley.

Jacobins.—First, H. Yardley. Second, J. Percivall.

Fantails —First and Second, H. Yardley.
Owls.—Prize, R. Fulton.
Trumpeters.—First, T. Crunden, jun., Burgess Hill. Second, R. Fulton. Commended, H. Loe.
Barbs.—First, R. Fulton. Second, J. Percivall. Highly Commended, H. Yardley; R. Fulton.
Tumbits.—Prize, H. Yardley.
Nuns.—Prize, H. Yardley.
Archangels.—First and Commended, H. Yardley. Second, J. Percivall.
Any other Distinct Variety.—First, F. Else (Ice Pigeons and Trumpeters). Second, H. Yardley. Commended, H. Yardley; F. Pittis, jun. (Magpies and Swiss).

THORNE POULTRY AND PIGEON SHOW.

At no previous meeting of the Thorne Society has there been so large an entry, nor, as a whole, so good a competition for general quality, as at that held on the 19th inst. This Show has always been very popular—in fact, the great annual event of the neighbourhood; and it has often been remarked that it is quite "a lady show," as well as one for poultry. This year, however, the attendance of the fair sex was very limited, for the day was very unfavourable, rain falling from daybreak. Even under such adverse circumstances the unremitting courtesy and attention of Mr. Richardson, the Honorary Secretary, deserved, and received, the highest praise. The arrangement of the pens was exceedingly good; of fowls alone there was a length in pens of 320 yards, besides which there were other long lines of coops for the Turkeys, Geese, Ducks, Rabbits, and Pigeons.

The *Spanish* classes were most excellent, and, strange to say at this season, they were shown in exceedingly good condition: hence this portion of the Show was very attractive. Mr. J. Thresh, of Bradford, showed some very creditable pens. *Cochins* were good, Buffs taking the first position, but closely pressed by some very superior Partridge-coloured. The Dark *Brahmas* were very good, but little can be said in favour of the Light ones. *Dorkings* were well shown. In the *Game* classes the competition was unusually severe; and Messrs. Aykroyd, Mellor, Julian, Brierley, Hellewell, Chaloner, and Butcher, may well boast of success, the condition of the generality of their birds being perfect. Although only three pens of *Polands* were entered, they were remarkably good. The *Hamburgh* classes, in which there were heavy entries, were also of great merit. The *Game Bantam* class was first-rate, Mr. Crossland, of Wakefield, with only three pens (all Black Reds), taking both prizes and a high commendation. The two hens in the first-prize pen were such as we have not seen for a long time past.

Some splendid specimens of the Mandarin and also the Pintail *Ducks* placed Mr. Harrison, of Hull, at the head in the Extra Duck class. There was a close rivalry as regards both *Pigeons* and *Rabbits*. In *Extra Stock*, a very fine pair of Chinese Silver Pheasants and a Turkey hen busily engaged in attending to a family of thirteen poults, seemed to cause much interest among the visitors.

The Show ground had been very carefully and successfully decorated; and as it naturally possesses great attractions, a bright sunny day would have been the only requisite to have made this year's Show the most successful ever held. We trust that another season better weather may attend this Society's meetings, as the Show is only open a single day—a limitation as to time which is no doubt greatly appreciated by the owners of competing stock, but which sadly limits the receipts if the day prove a rainy one.

Spanish —First, J. Thresh, Bradford. Second, Messrs. Burch & Boulter, Sheffield. Highly Commended, H. Beldon, Bingley; J. Marchant, Halifax.
Cochin-China.—First, H. Beldon. Second, T. M. Derry, Gedney. Highly Commended, W. A. Taylor, Manchester.
Brahma Pootra —First, E. Leech, Rochdale. Second, J. W. Harrison, Spalding.
Dorkings.—First, Mrs. Arkwright, Etwall Hall. Second, H. Beldon. Highly Commended, J. White, Warlaby.
Game (White and Piles).—First, Rev. W. J. Meller, Colwick. Second and Commended, R. Butcher, Cressywell (Piles).
Game (Black-breasted and other Reds).—First, C. W. Brierley, Middleton. Second, G. Hellewell, Walkley. Highly Commended, E. Aykroyd, Bradford; H. Beldon; R. Williamson, Wheatley Bar; D. Gambles, Hatfield; C. Chaloner, Whitewell; J. Laming, Spalding.
Game (Duckwings and other Greys and Blues).—First, Master G. Cocking, Curlew House. Second, H. M. Julian, Hull.
Game (Any variety).—First and Silver Cup, C. Chaloner. Second, E. Aykroyd. Highly Commended, J. Fletcher, Manchester; H. M. Julian; Messrs. Sales & Bentley, Crowle; C. W. Brierley. Commended, C. Chaloner. *Cock.*—First and Silver Cup, H. M. Julian. Second, E. Aykroyd. Highly Commended, Messrs. Sales & Bentley; J. Laming; C. W. Brierley, Middleton. Commended, J. Fletcher.
Poland (Any variety).—First and Second, H. Beldon (Silver-spangled and Blacks). Highly Commended, W. Harvey (Golden-spangled).
Hamburghs (Silver-spangled).—First, H. Beldon. Second, J. A. Taylor, Manchester.
Hamburgh (Golden-spangled).—First, H. Beldon. Second, J. White, Whitley, Netherton. Highly Commended, T. Walker, jun., Denton; W. Wood, Sheffield. Commended, J. A. Taylor.
Hamburgh (Silver-pencilled).—First, H. Beldon. Second, W. Wood.
Hamburgh (Golden-pencilled).—First, W. Wood. Second, H. Beldon. Highly Commended, F. Hollings, Bradford.
Any other Distinct Variety.—First, R. Loft, Woodmansey (Sultans). Second, R. Pashley, Worksop (La Flèche). Highly Commended, Hon. W. G. Eden, Elmfield (Houdans). Commended, P. Winkelman, Gomersal (Houdans); Col. Stuart Wortley, London (Crève Cœurs).
Any Farmyard Cross.—First, R. Loft. Second, G. Robinson, Frodingham, Driffield. Highly Commended, H. Beldon.

Game Bantams (Any breed).—First and Second, Master E. Crossland, Wakefield. Highly Commended, Master E. Crossland; J. Fletcher. Commended, G. L. Curtis, Selby; R. Charlesworth, Manchester; Rev. H. C. Russell, Doncaster.
Bantams (Silver or Golden-laced).—First, Messrs. S. & R. Ashton, Mottram. Second, J. Walker, Halifax. Commended, T. C. Harrison, Hull.
Bantams (Black, White, or any Colour).—First, W. A. Taylor. Second, R. Bentley, Finningley Park. Highly Commended, W. A. Taylor. Commended, J. R. Jessop, Hull (Black).
Single Cock (Any breed).—First, W. A. Taylor (Buff Cochin). Second, H. Beldon. Highly Commended, W. Harvey (Partridge Cochin). Commended, R. Pashley, Worksop (Dark Brahma); Col. Stuart Wortley (Brahma); G. Holmes, Driffield (Golden-spangled Hamburgh). *Hens.*—First, J. Thresh, Bradford (Black Spanish). Second, R. Pashley (Brown Red Game). Highly Commended, H. Beldon (Golden Polands); M. Farrand, Dalton (Black Spanish); W. Harvey (Partridge Cochins). Commended, Mrs. Arkwright (Grey Dorkings); Rev. W. J. Meller (Dark Brahma); Messrs. H. & S. Cooper, Walsall (Spanish); Col. Stuart Wortley (Buff Cochin); Messrs. Burch & Boulter (Spanish). *Cockerel and two Pullets.*—First, Messrs. Burch & Boulter (Spanish). Second, W. Wilkinson, Wath (Black Red Game). Highly Commended, Mrs. J. Newman, Worsborough (Dark Brahmas); W. F. Entwisle, Leeds (Black Red Game Bantams); F. Key, Beverley (Grey Dorkings). Commended, A. Bamford, Middleton (Buff Cochin-China).
Guinea Fowls.—First, T. C. Harrison. Second, H. Merkin, Driffield. Highly Commended, Miss Chester, Dykesmarsh.
Turkeys.—First, E. Leech, Rochdale. Second, H. Merkin. Highly Commended, Rev. W. J. Meller.
Extra Stock.—Commended, Miss Smith, Hatfield (Turkeys).
Geese.—First and Second, J. White (Toulouse). *Gibs.*—First, Mrs. S. Hodgson, Thorne (White). Second, J. Hepworth, Bearswood Green (Grey). Highly Commended, Master J. C. Coalman, Thorne; Miss L. Outwin, Hatfield Parks; C. Haycroft, Thorne.
Ducks (Aylesbury).—First, E. Leech. Second, O. A. Young, Driffield.
Ducks (Any breed).—First and Second, T. C. Harrison. Highly Commended, R. Bentley, Finningley Park.
Extra Stock.—Highly Commended, F. Sales, Crowle (Silver Chinese Pheasants).

RABBITS.

Buck and Doe.—First, Messrs. Hanson & Wagstaff, Thorne. Second, C. Singleton, Thorne. Commended, A. H. Easten, Hull; H. T. Marriott, Wirksworth.
Buck.—First, F. Roberts, Thorne. Second, A. H. Easten. Highly Commended, Messrs. Hanson & Wagstaff; J. Owen, Sheffield. Commended, J. Bradley, Hatfield. *Doe.*—First, R. Dobson, York. Second, Messrs. Hanson & Wagstaff. Commended, J. Mangham, Sheffield; A. O. Young.
For Weight.—First, W. Gant, Doncaster. Second, G. Chester, Thorne. Highly Commended, J. Owen.
Extra Stock.—First and Second, H. Cawood (Himalaya).

PIGEONS.

Carriers.—First, — Newbitt, Epworth. Second, E. Horner, Harewood. Highly Commended, H. Yardley.
Croppers.—First, Master E. Crossland, Wakefield. Second, F. Key. Highly Commended, H. Yardley. Commended, Messrs. Newbitt; T. Burgess, Brighouse.
Tumblers.—First, F. Key. Second, H. Yardley. Highly Commended, H. Cawood; G. Kelsey; C. Gravil, jun. Commended, T. Burgess.
Jacobins.—First and Second, E. Hornes, Harewood. Highly Commended, F. Key. Commended, H. Grant.
Nuns.—First and Second, J. Marshall, Driffield. Commended, H. Yardley.
Trumpeters.—First, E. Horner. Second, S. Robson, Brotherton. Highly Commended, C. Gravil, jun.
Turbits.—First, E. Horner. Second, Messrs. Newbitt. Highly Commended, H. B. B. Laycock, Woodville; J. Marshall, Driffield. Commended, Master E. Crossland; J. Marshall.
Fantails.—First, E. Horner. Second, H. Yardley. Highly Commended, H. Yardley; J. Ellrington, Woodmansey. Commended, Messrs. Newbitt.
Owls.—First, E. Horner. Second, H. B. Laycock. Highly Commended, H. Yardley.
Barbs.—First, E. Horner. Second, E. Brown. Commended, H. Yardley; T. Burgess.
Extra Stock.—Messrs. Newbitt (Fairy Swallows).

The Judges were Mr. Harry Adams, of Beverley, and Mr. Edward Hewitt, of Birmingham.

PROMOTING SWARMING—CONFINING BEES.

I have an old cottage hive which I have been expecting to swarm for the last fortnight. The bees are clustered about the mouth of the hive and hang nearly to the ground, more or less, according to the weather, but they will not swarm. Would it be advisable to sweep them off into a hive, or let them remain to swarm in their usual way?

I had a strong swarm last year which I put into a bar-and-frame hive (straw), which did exceedingly well all summer, and stood the winter; they came out during the few fine days in February, and were very active. The second frost and snow then came, when I put the perforated zinc before the entrance as usual during the snowy weather, but when the snow cleared I found nearly all the bees dead, and how to account for it I know not. They had plenty of honey, and they were well covered up. They stand by the side of a cast I had put into a wooden bar-and-frame hive which was too large for them, so I had to feed, and did not expect them to live, but they are doing exceedingly well. Some of the bees work, and some appear idle. A fortnight ago I took the crown-board off, and

took out some of the side frames, and found many of them sealed up. When I came to the centre one I found some young bees ready to come out of the cells. I did not look for the queen, nor did I take out all the frames, as it appeared to irritate the bees. If I be so fortunate as to have a cast from the old hive, would it be advisable to put them to this hive to strengthen them, or let them remain as they are?

Would you also be pleased to inform me which is the best practical work on bee-keeping?—J. W. G.

[Sweeping the clusters of outlying bees into another hive would do no good, as they would speedily leave it and return to their old domicile. Why not drive all the bees into an empty hive and establish them as an artificial swarm on their old stand; then cut out their combs and appropriate those containing honey, fitting the brood-combs into frames and applying them to strengthening the other stocks?

The colony in the first-mentioned frame hive was weakened by your mistaken kindness in confining the bees during snow, the mortality which ensued being, doubtless, owing to suffocation caused by an accumulation of dead bees in the doorway.

"Bee-keeping for the Many," published at this office, price 4*d.*, free by post for five stamps.]

TRAPPING DRONES.

How can I trap drones at the mouth of the hive? I placed an old stock upon a square box, which the bees have nearly filled. Will there be any danger of the queen being in the box when I take it off? If so, what will be the result?—Baron.

[The Germans trap drones in a wire receptacle attached to the hive's mouth. This receptacle is made of such a mesh as to retain the drones whilst the workers escape, and when filled is plunged into boiling water. The queen is very likely to be in the lower box, to which the seat of breeding may very probably be transferred. In this case the top hive should be removed, but there is a probability of too great a proportion of drone combs being built in the nadir, and this may seriously impair the future prosperity of the colony.]

UNITED SWARMS.

On the 11th inst., I had a first and second swarm (from two separate hives), which I shook into Stewarton-boxes, uniting them together the same evening by drawing the slides. The union was accomplished pretty amicably, only a few dead bees being observable the next morning. For room they were allowed three body boxes of the Stewarton hive, and on the evening of the 12th the two united swarms filled the two top boxes completely. On the 13th they seemed to work very well, and the same evening the two boxes were filled as before. On looking at them this evening, June 14th, I found that only the top box was filled with bees, the second box being completely empty. Am I to conclude that one of the swarms has taken its departure? This morning they seemed busy at work, and I had concluded that all was well, but am now afraid that I have lost one of the swarms.—D. C.

[You need not be uneasy. The desertion of the second box was doubtless owing to a fall in the temperature, causing the bees to cluster more closely together, and, therefore, to occupy a smaller space.]

SWARMS.

On June 10th, a swarm of bees came from one of my two hives, and after flying about in the air some minutes returned to the hive they came from. On the 18th, a swarm came from the same hive, which I secured. To-day (21st), another swarm came off from the same hive, which I also secured. Will you kindly tell me which you consider the first swarm, the one which returned, or that which I first secured? Can you also tell me the cause of the swarm returning, and whether there is likely to be any more swarms from the hive mentioned this season? The super at top is only half full of comb.—A Bee Amateur.

[The queen either remained behind or dropped on the ground and was lost, and, therefore, the bees returned to the hive. The swarm which you secured on the 18th was, we should think, the first. We can offer no opinion as to the probability of a further issue.]

OUR LETTER BOX.

Hatching in an Incubator (*G. M.*).—Eggs do not take longer to hatch in an incubator than under a hen.

The French Fowl Le Brest (*E. H. C.*).—We do not think well of the "Le Brest" fowl—that is, we prefer the other breeds. Of all the French importations, the Houdan is in our opinion the hardiest, and a capital winter layer. The La Flèche and Crève Cœur produce very large eggs, but we have had much trouble with the cocks. They die, or live in a dying state, while the pullets thrive well in the same yard and on the same food.

Young Turkeys Picking their Feet (*J. M.*).—Your Turkeys need something which they have not, or there is something in the soil that adheres to their feet and causes discomfort. Give them some lettuce, and put some brimstone in the water they have to drink.

Dorking Chickens Crooked-breasted (*O. P.*).—We do not think the short time the chickens roost on the sharp rails in the neighbourhood of their haunts would have any effect on their breasts, but sharp or narrow perches in their roosting-places may have much to do with them. We have often noticed that chickens are ambitious to roost where as adults they do not care to do so. There is little doubt that crooked breasts are hereditary in some strains. If, however, you had none last year, and are still breeding from the same stock, it cannot be so in your case. Fast-growing chickens when roosting on narrow perches are obliged to cling closely with their feet; but as they often lack sufficient strength to hold on, they, to avoid see-sawing, rest their breasts on the perch. There is no doubt that, as it is at this age quite cartilaginous, it takes easily the formation of a round and narrow resting-place. Our own chickens, though now good-sized, do not roost in a house. They live out of doors, and at night either get under hayricks or into the rips which they occupied when they were young and smaller. We keep them out of doors as long as possible, but when they are put in houses at night we allow them perches within 2 feet of the ground, and made of fir poles 16 inches in circumference, sawn through the middle, and placed, with the bark on, round side uppermost. It depends much on the competition whether Dorkings with crooked breasts would be successful at a show. If they were very crooked it would be much against them; if only slightly so, and other points were favourable, they would win in spite of it.

Chickens Drooping (*R. C.*).—When your chickens droop feed them on bread and ale. If they are supplied with strongly camphorated water it will do much for them. A pill of camphor the size of a garden pea is beneficial to an adult, while one half the size is a sufficient dose for a chicken. We know no publication now that gives the rules of the pit, or instructions for training cocks. Such things are out of print; but in some parts of the north and north-west they have been correctly handed down from father to son.

Brahma Pootra's Feather (*W. D.*).—The feather you enclosed may have belonged to a perfectly pure Brahma cock, but he was an old bird. We should not impugn the purity of a young bird for such a feather, but we should not keep him. The hen's beak cannot grow again, and when she has reared her brood she should be consigned to the cook. She will do no good, and the trouble her injury causes is all labour thrown away.

Diarrhœa in Chickens.—"I think that bread or toast soaked in port wine is a good remedy for diarrhœa in chickens that are not too young for wet or damp food.—T. D."

Preserving Eggs (*G. S.*).—Take a bread-pan or other pan, put slaked lime into it, till it has enough to allow the eggs to stand upright small end downwards. As soon as the layer is completed, fill up till they are covered and there is an even surface. When you have enough of eggs to make another layer, then put in slaked lime sufficient to be filled up by the eggs you have ready. You may continue till the pan is full. If the eggs are put in fresh you may keep on, and they will be fit for breakfast at any time, and be the same as new-laid eggs. You must recollect, if they are stale when put in this process will not restore them. There are cases we can neither understand nor prescribe for. Yours as regards the Dorking cock may be one of them. You must judge for yourself as regards the Dorking cock. If you have one to take his place, take no more trouble about him—put him in the stock-pot. If you have not, we can only advise you to persevere.

Spanish Cock's Face (*White-faced Spanish*).—Your bird with the white wrinkles grown over his eyes has what is called a cauliflower face. We doubt whether he will recover from his blindness. Wash his face carefully with equal parts of cold water and vinegar. At this time of year the hens often peck the cock's face, and cause the blindness you complain of. Put him by himself, and try the application. Many of the best birds suffer from this and become useless.

Foul Brood (*M. Y. L.*).—This terrible malady is very infectious, and is a disease, not of the bees, but of their brood, which dies in the cells and becomes putrid and offensive, emitting a very disagreeable odour. It can rarely be identified, except in moveable comb hives, until the stocks are dead, when the foul state of the combs makes it evident enough. Its first cause has not been detected, although various hypotheses have been mooted on the subject. A long discussion on foul brood took place in our pages during the autumn of 1863, and continued until the spring of 1864. A graphic description of the ravages committed by this disease in the apiary of "A Devonshire Bee-keeper," and the means by which he finally banished it, will be found in Nos. 121, 122, and 123 of our new series.

Destruction of Drones (*T. R. Drake*).—This premature expulsion of the male element is owing to the failure of the honey harvest, and is therefore unusual at this season. The unfortunate drones have doubtless been denied access to the dwindling stores of food, until, weakened by starvation, they have been entirely banished from the hive.

Honey Harvest (*S. E. V. D.*).—There can, we think, be no doubt that the honey harvest up to the present time has been but scanty. How far bees benefit directly by honeydews is a disputed point. They certainly collect honey in abundance at such times; and we have occasionally, although rarely, seen a bee licking the saccharine deposit from the leaves.

A Book (*A Subscriber*).—Write to Mr. W. J. Pettitt, Snargate Apiary, Dover, enclosing twenty postage stamps with your direction.

Caterpillars of Bombyx cynthia.—*Bromley* wishes to know if these can be fed on mulberry leaves. We never knew them fed on anything but leaves of the Ailanthus.
